This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Mab, a fairy celebrated by Shakespeare, Ben Jonson, and other poets. She is usually called Queen Mab, but this does not mean that she is queen of the fairies. That place belongs to Titania, the wife of Oberon. For a description of Queen Mab's mischievous ways, telling how she comes "athwart men's noses as they lie asleep," etc., see Shakespeare's *Romeo and Juliet.* In Shelley's *Queen Mab,* she is made queen of the fairies and given a much wider realm to reign over, —the deeds and thoughts of men.

Macad'am, John Loudon, inventor of the system of roadmaking known as "macadamizing," was born at Ayr, Scotland, Sept. 21, 1756. In 1801, he began to make experiments in road-building, a work to which his future life was devoted. His system was adopted on nearly all the public roads of England, and was introduced into France and other countries. The principles of his system may be briefly stated: In constructing a road it is not necessary to lay a foundation of large stones, as it is a matter of indifference whether the foundation be hard or soft. The material for the road must consist of broken stones, one or two ounces in weight, scattered to a depth of from six to ten inches, and pressed together as closely as possible. The road is to have a slight fall from the middle to the sides, and ditches are to be dug on each side of the road of sufficient depth to drain it. Macadam was offered the honor of knighthood some time before his death, but declined it. He died at Moffat, Dumfriesshire, Nov. 26, 1836.

McAll' Mission, the largest Protestant mission in France, was founded in 1871 by Rev. R. W. McAll and his wife. It embraces more than one hundred stations, nearly all of which are in the city of Paris, and is supported by Protestants of all denominations in both England and America. Such has been the progress of this mission that in the 12th year after its foundation it held 15,000 meetings, attended by nearly 1,000,000 persons, and distributed more than 500,000 Bibles and tracts.

Macaroni (*mǎk-a-rō'nĭ*), a peculiar paste or dough manufactured from wheat flour into tubes, ribbons, or threads. It is an Italian invention, and although the process is very simple, the manufacture of macaroni is almost wholly limited to Italy and France, probably because the wheat raised in those countries contains so large a proportion of gluten. Macaroni is used for soups, and is exported to all parts of the world.

MacAr'thur, Arthur, American soldier, major-general in the regular army, was born in Massachusetts, but served during the Civil war in the western army; entering the service as a lieutenant in the 24th Wisconsin Infantry, Aug. 4, 1862, and rising to a brevet colonelcy, given for conspicuous bravery at the successive engagements of Perryville, Stone River, and Missionary Ridge. For his gallantry in the latter engagement he was voted a medal by congress. He served throughout the Atlanta campaign and was mustered out only after the final review of the volunteer forces, June 10, 1865. The next year, Feb. 23, 1866, he was commissioned as first lieutenant in the regular army and assigned to the 17th Infantry; but a few months later he was promoted to a captaincy and transferred to the 36th Infantry. At the outbreak of the war with Spain, he was serving in the office of the adjutant-general with rank of lieutenant-colonel. On May 27, 1898, he was appointed brigadier-general of United States Volunteers, and promoted to major-general commanding 2d division, 8th army corps soon after, and assigned to duty in Havana. In 1899, he was sent to the Philippines where he rendered conspicuous service, was made brigadier-general in the regular army, and, on the retirement of General Otis, was placed in command of the army in the Philippines and also made military governor of the islands. In February, 1901, he was promoted to major-general in the regular army.

McAr'thur, Duncan, an American pioneer, was born in Dutchess county, N. Y., June 14, 1772. He was with General Wayne in his campaign against the Indians in 1797, and soon after that settled in Ross county, O., where he acquired a large landed estate. In the War of 1812, he was commissioned brigadier-general in the army, and in 1814 succeeded General Harrison in command of the army of the west. As such he partly executed a bold plan for conquering upper Canada, which he was obliged to relinquish on account of the failure of other forces to cooperate with him. He served a term in congress, 1823–25, and was governor of the state from 1830 to 1833. He died in Ohio, April 28, 1839.

Macassar (*ma-kăs' sar*), a strait about 400 miles long and from 100 to 200 miles wide, connecting the Java and Celebes seas, and separating the island of Celebes from that of Java.

Macaulay (*ma-kaw'lī*), **Thomas Babington,** Lord, a great English historian and essayist and the most pictorial prose-writer in English literature, was born in the village of Rothley, Leicestershire, Oct. 25, 1800. From his earliest infancy he showed an eager desire for knowledge and remarkable capacity for composition, both in prose and poetry. As a boy he attended a private school kept by Mr. Preston, a low-church clergyman, and at the age of eighteen entered Trinity college, Cambridge. His university career was very brilliant, in spite of his dislike to mathematics. Macaulay was admitted to the bar soon after his graduation; but his love of literature was so great that he made no effort to secure a legal practice. At the age of twenty-five, he published an essay on Milton, in the *Edinburgh Review*, which at once placed him in the highest rank of literature, and for nearly twenty years afterward he continued one of the principal writers for that magazine. In 1830, Macaulay entered parliament, where his powers as a debater and orator proved fully equal to his talent as a writer. In 1834, he accepted the position of legal adviser to the supreme council of India, at a salary of £10,000 ($50,000) a year. He remained in India four years, during which, in addition to the duties of his office, he gave considerable time and attention to the preparation of a new India penal code, and also wrote his essays on Bacon and Sir James Mackintosh. Macaulay was elected to parliament from Edinburgh the year after his return from India, and during the few years he continued in public life greatly increased the fame he had previously won. In 1848, appeared the first two volumes of his great work—*History of England from the Accession of James II.* The popularity of this book was, perhaps, greater than was ever secured by any history, and the interest and delight with which it was read were almost beyond description. The third and fourth volumes appeared in 1855, and were received with the greatest favor and enthusiasm, both in England and America. In 1857, Macaulay was made a peer of the realm under the title of Baron Macaulay of Rothley. In the same year he was elected a foreign associate of the French Academy of Moral and Political Sciences. He died Dec. 28, 1859, and was buried in Westminster Abbey, Jan. 9, 1860. See *Life and Letters*, by Trevelyan.

LORD MACAULAY.

Mac'beth', a Scottish king, whose name has been immortalized by Shakespeare in his matchless play, *Macbeth*. In 1040, he slew Duncan, king of Scotia, and succeeded him on the throne. His seventeen years' reign is described in the chronicles as a time of plenty. Alone of Scottish kings he made a pilgrimage to Rome (1050), where he gave very large alms to the poor. In the year 1057, Malcolm Duncan, who had fled to England after the murder of his father, returned to Scotland, and, marching a hostile force against Macbeth, defeated and killed him at the battle of Lumphanan, after which Malcolm was proclaimed king.

Maccabees (*măk'ka-bēz*), the name assumed by the patriotic Hebrew Mattathias (and his descendants), who first resisted the persecutions inflicted upon the Jewish people by the Syrian king, Antiochus Epiphanes (175–164 B. C.). Mattathias had retired with his five sons, at the beginning of these troubles, to a small place called Modiin, between Jerusalem and Joppa, to mourn over the desolation of the city and the desecration of the temple. He was pursued to this point by the Syrians, and when one of their captains tried to bribe him to abandon the Jewish faith, he answered by slaying with his own hand the first Jewish renegade who approached the altar of idolatry. This bold act was the signal for a general outbreak. The five sons of Mattathias, with a few faithful followers, rose against the national foe, destroyed all traces of heathen worship, and then fled into the wilderness of Judæa. Not long after, they entered the adjacent cities and villages, circumcising the children, and restoring the ancient religion of Jehovah. At the death of Mattathias, 166 B. C., his son Judas took command of the patriots, repulsed the enemy at Mizpah and other places, reconquered Jerusalem, purified the temple, and restored the worship of Jehovah. Having further concluded an alliance with the Romans, he fell in battle with Bacchides. Judas was succeeded by his brother Jonathan, who also acquired the dignity of high priest. Jonathan was treacherously murdered at Ptolemais, 141 B. C., and was succeeded by his brother Simon, the second of the five sons of Mattathias. The reign of Simon marked a new era in Jewish history. His power was almost absolute, but it was exercised with great moderation and "Judah prospered as of old." The reign of the Maccabean family continued until the time of Herod the Great. See *History of Israel*, by Ewald; *History of the Jews*, by Milman.

McCarthy (*mă-kär'thī*), **Justin,** Irish historian and novelist, was born at Cork, Nov. 22, 1830. He joined the staff of the *Northern Times*, Liverpool, in 1853, and in 1864 became chief editor of the London *Morning Star*. He resigned this position in 1864, and devoted the next three years to a tour

through the United States. He entered the house of commons in 1879, as member of Longford, a liberal, but his literary works have extended his name much further than his political triumphs. Among his best-known novels are, *Paul Massie* (1866), *The Waterdale Neighbors* (1867), *My Enemy's Daughter* (1869), *Miss Misanthrope*, *Dear Lady Disdain*, *Donna Quixote*, *Maid of Athens*, *Red Diamonds*, *A Fair Saxon*, etc. His historical writings, on which his fame mostly depends, are *History of Our Own Times*, *History of the Four Georges*, *Epoch of Reform*, *Life of Sir Robert Peel*, *Life of Pope Leo XIII.*, *Modern England*, *Reminiscences*, *The Story of Mr. Gladstone's Life*.

JUSTIN M'CARTHY.

McClel'lan, George Brinton, an American general, was born at Philadelphia, Dec. 3, 1826. He graduated at the West Point Military academy in 1846, one of his classmates being the renowned "Stonewall" Jackson. He served as an engineer during the Mexican war, winning a brevet-captaincy by his skill and bravery. He continued to serve as an officer in the regular army until 1857, when he resigned his commission to engage in railroad business. When the Civil war broke out, in April, 1861, Governor Dennison of Ohio appointed him major-general of Ohio volunteers, and in May he was appointed major-general of United States troops by President Lincoln. He was immediately sent into West Virginia, and during the month of July conducted a short and very successful campaign against the Confederates in that state. On account of this signal success of McClellan, he was soon after called to Washington to reorganize the army of the Potomac and prepare it for another advance upon the enemy. On the retirement of General Winfield Scott, in November following, McClellan was made commander-in-chief of the army. As an organizer, he showed marked ability and efficiency; but he sorely tried the patience of both the administration and the people by the slowness of his movements—rather than by his failure to move at all. At length, in April, 1862, under the positive orders of the President, he entered on his disastrous Peninsular campaign. He advanced within a few miles of Richmond, but after fighting what is known as the "Seven Days' battles" (June 25 to July 1), he was driven back and was directed to abandon the peninsula. A large part of his army was now ordered to re-enforce General Pope's troops; but soon after the second battle of Bull Run, McClellan, in command of his army of the Potomac, marching northward, met the forces of General Lee at Antietam, Maryland, where there occurred one of the bloodiest battles of the war; but whatever advantage McClellan gained by this fight he failed to follow up, and General Lee was allowed to recross the Potomac without being molested. McClellan followed him into Virginia; but all his subsequent movements were so unsatisfactory to the President and cabinet, that in November he was relieved of his command and General A. E. Burnside appointed in his place. In 1864, he was the Democratic candidate against Lincoln for the presidency, but received the electoral vote of only three states—New Jersey, Kentucky, and Delaware. In 1877, he was elected governor of New Jersey, and filled that office for a term of years. He died at Orange, N. J., Oct. 29, 1885.

GENERAL GEO. B. M'CLELLAN.

McClin'tock, Sir Francis Leopold, was born at Dundalk, Ireland, in the year 1819, and entered the navy when only twelve years old. He served in Austin's expedition in search of Sir John Franklin in 1850, and made a sledge journey of several hundred miles along the northern shore of Parry sound. In 1857, he took command of the expedition fitted out by Lady Franklin to search for her husband. For his success in ascertaining the fate of Franklin, in addition to many other honors, he was knighted in 1860. During the same year he published a book containing a full account of his voyage in the Arctic seas in search of Franklin and his companions, entitled *The Fate of Sir John Franklin;* he has also published, *The Voyage of the Fox*. During the years 1879–82 he was commander-in-chief of an English squadron on the North American and West India station.

CARDINAL M'CLOSKEY.

McCloskey (*ma-klŏs'kĭ*), **John,** a cardinal of the church of Rome in America, was born at Brooklyn, N. Y., March 20, 1810. After pursuing a collegiate and theological course at St. Mary's college, Emmitsburg, Maryland, he was ordained a priest at St. Patrick's cathedral,

New York, Jan. 9, 1834. He was consecrated bishop March 10, 1844; archbishop May 6, 1864, and in 1875 was created cardinal, being the first American raised to that princely dignity. He died at New York, Oct. 10, 1885.

McCook', Gen. Alexander McDowell, was born in Columbiana county, O., April 22, 1831. He graduated at West Point in 1852, and after several years' service in the army was appointed instructor of infantry tactics in that institution. He was appointed colonel of the first Ohio regiment organized for service in 1861, which he commanded at the battle of Bull Run, July 21, 1861. He was afterward promoted to the rank of major-general, and as such commanded a division at the battles of Shiloh and Perryville. When General Rosecrans was placed in command of the army of the Cumberland, McCook was assigned to the command of the 20th army corps, with which he took part in the battles of Stone River and Chickamauga. Since the war he became colonel of the 6th Infantry, and was for a time in charge of the Military school at Fort Leavenworth. In 1895, he retired with the rank of major-general.

GEN. ALEX. M. M'COOK.

McCook', Gen. Daniel, was born at Carrollton, O., July 22, 1834, and graduated at Florence college, Alabama, 1857. He entered the Union army as colonel of the 51st Ohio volunteers in 1861, being afterward promoted to the rank of brigadier-general. In addition to a number of minor engagements, he participated in the battles of Perryville, Chickamauga, Missionary Ridge, and Kenesaw Mountain, Ga., in the latter of which he was killed, July 21, 1864.

McCook', Gen. Robert Latimer, was born in Columbiana county, O., Dec. 28, 1827. He was commissioned colonel of the 9th Ohio volunteers on the outbreak of the Civil war, and commanded a brigade in West Virginia under General Rosecrans, in the summer of 1861, highly distinguishing himself in a number of engagements. He was in command of a brigade in General Buell's army in August, 1862, when he was shot by guerillas while sick and traveling in an ambulance near Salem, Ala.

McCor'mick, Cyrus H., inventor of the McCormick reaping machine, was born at Walnut Grove, W. Va., Feb. 15, 1809. In the year 1847, he moved to Chicago, where he engaged in the manufacture of his machine, which soon came into extensive use, both in the United States and other countries. He amassed a large fortune and became noted for his great liberality. In 1859, he endowed the Presbyterian Theological seminary, at Chicago, which bears his name, and which is one of the best equipped and most prosperous educational institutions of the country. The total amount contributed by Mr. McCormick and his heirs to this and other institutions is over $1,000,000. Mr. McCormick died at Chicago, May 13, 1884. At the head of the great industry connected with his name, the McCormick Harvesting Machine company, is now Cyrus Hall McCormick, born in 1859 and graduated from Princeton in 1879. His uncle, Leander J. McCormick (born 1819), is known to the world of commerce to-day as the inventor-capitalist.

McCosh', James, a Scottish-American educator and philosopher, was born in 1811, in Ayrshire, Scotland. He was educated at the universities of Glasgow and Edinburgh, and while there earned the honorary degree of M. A. by his paper on the *Philosophy of the Stoics*, through the influence of Sir William Hamilton. He was ordained at Brechin a minister of the Church of Scotland in 1835, but joined in the Free-church movement in 1843. He was called to the chair of logic and metaphysics in Queen's college, Belfast, in 1851, and remained there until 1868, when the College of New Jersey, at Princeton, elected him as its president. By this step the college gained great benefit, for he imparted to it new life, and secured for it large donations by his personal influence. The writings of Dr. McCosh are marked by keen insight as well as clearness of statement; he belongs to the Scottish or "common sense" school of philosophy. The most important of his works are: *The Methods of Divine Government, Physical and Moral; Typical Forms and Special Ends in Creation; Intuitions of the Mind Inductively Investigated; An Examination of Mill's Philosophy; Laws of Discursive Thought; Logic; Christianity and Positivism; A Work on Scottish Philosophy*, besides papers on education and the relation of science to religion. In 1888, he resigned his office as president, to give his attention more closely to philosophical writing, and published *First and Fundamental Truths*, and *Religious Aspects of Evolution*. He died at Princeton, N. J., Nov. 16, 1894.

JAMES M'COSH.

McDon'ald, Sir J. Alexander, D. C. L., a Canadian statesman, was born in Scotland in

1815, but removed to Canada when a child. He was admitted to the bar in 1836, when barely twenty-one, and was elected to the Canadian parliament as a Conservative, in 1844, from Kingston, Ontario. Three years later, he became a member of the executive council, then receiver-general, and, not long after, commissioner in charge of the public lands of the colony. The Liberal party was in power from 1850 to 1854, but in the latter year a coalition cabinet was formed in which he became attorney-general, retaining office till 1862, when, upon the defeat of an important bill, the whole cabinet resigned. He returned to the new cabinet formed by Sir E. P. Taché in 1864, holding the same office as in the previous ministry. In 1865, Sir John became minister of militia; in 1868, minister of justice, and in 1869, premier of the Dominion cabinet, retaining office until 1873. It devolved upon him to form a new cabinet in 1878, in which he reserved for himself the ministry of the interior. He continued in office until 1891, the year of his death, having been violently opposed to the policy of reciprocity which existed by treaty between the United States and Canada from 1855 to 1865. This policy was at that time terminated by the states themselves, and never resumed, although at the time of his death many leading Canadians desired to be embraced in the treaties to promote commerce which were being executed between the federal government and various other American states.

Macdonald (*măk-dō-năl'*), **Etienne Jacques Joseph Alexandre,** Marshal of France, was born Nov. 17, 1765, at Sancerre. He entered the army in 1784, and became a general in 1795, after having distinguished himself at Jemappes and also by crossing the Waal on the ice under the fire of the enemy. In 1800 and in 1801 he commanded the army of reserve in Switzerland, but in 1805 he lost the favor of Napoleon by his support of Moreau. Four years later, however, Napoleon placed him in command of the right wing of the army of Italy, and he so distinguished himself at the battle of Wagram that he was created marshal and also duke of Tarentum. In 1813, he was defeated by Blücher at the Katzbach, and at the battle of Leipsic he assisted to cover the retreat of the French. He adhered firmly to Napoleon until the latter's abdication; but during the "hundred days" refused to take any command under him. He lived in honorable retirement at Courcelles, near Guise, until his death, which took place Sept. 25, 1840. See *The Consulate and the Empire*, by Thiers.

Macdonald (*măk-don'ald*), **Flora,** a Scottish heroine, was born in the Isle of South Uist, one of the Hebrides, in the year 1722. She lost her father at the age of two years, and four years later her mother married Hugh Macdonald, of Armadale, in the island of Skye. Flora, however, was left behind in Uist for a number of years, but obtained three years' schooling at Edinburgh. After the defeat of Prince Charles Edward Stuart at Culloden, in the spring of 1746, under the disguise of "Betty Burke, the Irish woman," he was conducted by Flora from Ormiclade in Beubecula to Monkstadt in Skye, and thence by way of Kingsburgh to Portree, where the prince was committed to the care of Macdonald of Kingsburgh. They encountered great dangers, but Flora's wit and courage saved the young prince from capture and brought their voyage to a successful issue. She was soon after arrested by the government for her part in this affair, and held in mild captivity for about a year, during which she received a great deal of honor and attention from leading Jacobites. In 1750, she married the son of Macdonald of Kingsburgh, and became the mother of several children. They moved to North Carolina in 1774, and when the Revolutionary war broke out, her husband was commissioned a brigadier-general in the British service — her five sons were also British officers. Flora returned to Scotland in 1779 with her younger daughter, and during the voyage took part in an engagement between the vessel in which she sailed and a French privateer. Two years later, she was joined by her husband in Scotland, where they lived until her death, which took place in a neighbor's house at Kingsburgh, March 5, 1790. She was buried at Kilmuir in one of the sheets of the bed in which Prince Charles Edward slept the night he passed at Kingsburgh. Dr. Johnson, who was entertained by Flora in 1773, describes her as a woman "of middle stature, soft features, gentle manners, and elegant presence." He also says that "her name will be mentioned in history, and if courage and fidelity are virtues, mentioned with honor." See *Autobiography*.

Macdonald (*mak-dŏn'ald*), **George,** LL.D., a Scotch poet, novelist, and preacher, was born at Huntly, Aberdeenshire, Scotland, 1824; educated at King's college and Aberdeen university, studying subsequently at the Independent college, Highbury, London, for the nonconformist ministry. He preached for a short time in the counties of Surrey and Essex, but later became a lay member of the Church of England and devoted himself to literature. He visited the United States in the years 1872–73, lecturing and preaching in various cities. He published volumes of poems in 1855, 1857, 1864, 1868, and 1882. He also published a large

GEORGE MACDONALD.

number of novels, among which are *David Elginbrod; Adela Cathcart; Annals of a Quiet Neighborhood; Robert Falconer; Wilfrid Cumbermede; Malcom; The Marquis of Lossie; Sir Gibbie; Mary Marston; What's Mine's Mine; The Flight of the Shadow; The Light Princess; Lilith*, etc. His religious and theological works, including *The Hope of the Gospel, Gifts of the Child Christ*, etc., are not so well remembered; but some of them attracted no little attention at the time of their publication. His stories are of unequal merit, the *Annals of a Quiet Neighborhood* and *Wilfrid Cumbermede* being perhaps best known.

McDonough (*mak-dŏn'ō*), **Thomas,** an American naval officer, born in Delaware, Dec. 23, 1783. He became a midshipman in the navy in February, 1800, and belonged to the crew of the frigate *Philadelphia*, which was one of the squadron employed against Tripoli in 1803. He afterward served in the *Enterprise*, commanded by Decatur, and participated in the various attacks upon Tripoli in 1804. In 1814, during the second war with Great Britain, he commanded a squadron on Lake Champlain, and gained a decided victory over a British squadron under command of Captain George Downie. For this service he was promoted to the rank of captain and was presented with a gold medal by Congress. The legislature of Vermont also gave him an estate overlooking the scene of the engagement. He died at sea, Nov. 16, 1825.

McDow'ell, Irvin, a United States soldier, born in Franklin county, O., Oct. 15, 1818. He graduated at West Point Military academy in 1838; and during the Mexican war was brevetted captain for his gallant conduct at the battle of Buena Vista. At the opening of the Civil war, in 1861, he was commissioned brigadier-general, and placed in command of the army organized for an advance upon Richmond. His plan of the battle of Bull Run was without fault, and his conduct all that could be desired in a general; but he was unable to arrest the retreat of his troops, when they became panicstricken in the afternoon; and for some time after, McDowell was made the object of severe and unjust criticism. He was afterward placed in command of an army corps under McClellan and Pope, and was with the latter at the second battle of Bull Run, Aug. 29–30, 1862. He died at San Francisco, May 5, 1885.

Macduff', a Scottish nobleman (thane), and one of the leading characters in Shakespeare's immortal play of *Macbeth*.

McDuf'fie, George, a South Carolina statesman, born in Columbia county, Ga., in 1788. He began the practice of law at Edgefield, South Carolina, in 1814, and four years later was elected a member of the state legislature. In 1821, he became a member of Congress, and during the years he served in that body distinguished himself as an opponent of the protective tariff and an advocate of state-rights. He retired from Congress in 1834, after a bitter and vehement speech against the administration of President Jackson, and in the same year he was elected governor of South Carolina. When his term of office expired, he retired to private life, but, in 1842, he was chosen United States senator by the legislature of the state. Failing health compelled him to resign this office in 1846, which was the termination of his public career. He died in South Carolina, March 11, 1851.

Mace, the aril or inner covering of the nutmeg. It is blood-red, and somewhat fleshy when fresh. It is prepared for market by drying for some days in the sun. Mace is used as a spice, and its flavor is very similar to that of the nutmeg. It is imported chiefly from Penang and Singapore, where it is received from the Spice islands.

Macedo'nia, originally the name of a small country in Europe, lying north of Thessaly and the Ægean sea. Perdiccas I., about 700 B. C., is reputed to be the first king of Macedon, but it was not until the accession of Philip, 359 B. C., that the power of Macedon began to be felt by Greece and other nations. Philip applied himself very vigorously to developing the resources of his kingdom, and laid the foundations of the greatness it afterward assumed. His son, Alexander the Great, conquered Persia and brought half the known world under his sway; but a few years after his death the Macedonian empire was divided into four kingdoms under his principal generals. In 168 B. C., Macedonia was conquered by the Romans, and twenty-five years later was made a Roman province. The country is now under the dominion of Turkey.

Maceo (*mȧ'sā-o*), **Antonio,** a mulatto officer of the insurgent army in Cuba, was born at Santiago, Cuba, July 14, 1848. His family were people of humble position in the island, but inclined to side with the officers sent over from Spain. But upon the death of a brother, ruthlessly slain by a Spanish officer, he and his brother Josef joined the insurgents, and both rose to positions of great influence. His career during the ten years' war, 1868–78, displayed natural abilities as a soldier, and at Guimaro he defeated the Spanish troops under General Weyler. At the conclusion of peace, signed at Zanjon, 1878, he refused to accept the conditions, and retired to Costa Rico, Central America, where his time was mostly spent in preparation for a renewal of the war. He attempted, though unsuccessfully, to start another revolution in Cuba in 1890. He took part actively in the uprising of 1895, and, second only to Maximo Gomez, was rated the ablest of the insurgent leaders. He was killed by the Spanish troops in a skirmish near Mariel, Cuba, Dec. 2, 1896.

Macfarren (*mak-fär'en*), **Sir George Alexander,** English musical writer and composer, was born at London, March 2, 1813. He was educated at the Royal Academy of Music, and became a professor in that institution in 1834. In 1875, he was appointed principal of the academy, and also professor of music at Cambridge university. He was knighted in 1883, and died at London, Oct. 31, 1887. Macfarren's musical works are quite numerous; but he stands higher as a writer on the theory of music than as a musical composer — his aim being to revive the old English music in modern opera.

Macgreg'or, John, English canoeist, traveler, and philanthropist, was born at Gravesend, Jan. 24, 1825. He was educated at Trinity college, Cambridge, where he graduated with high honors in 1847. His love of travel caused him to make a tour through Europe, Egypt, and Palestine in 1849–50, and a few years later he also visited Canada and the United States. The rise of canoeing in England since 1850 was largely due to his influence and example. In 1866, he published an account of a canoe journey under the title of *A Thousand Miles in the Rob Roy Canoe*, which was followed by narratives of canoe voyages on the Baltic and Zuyder Zee, and by canoe trips on the Jordan, Red sea, and lake of Gennesareth. The profits of his lectures and works, amounting to over $500,000, he turned over to various philanthropic institutions. He died at Bournemouth, England, July 16, 1892.

Machiavelli (*mäk-i-ä-vĕl'i*), **Niccolo di Bernardo dei,** Italian statesman and diplomatist, was born at Florence, May 3, 1469, and died there, June 22, 1527. It was during the early years of his life that the Medici fled from Florence, and the republic was established under the influence of the great reformer Savonarola. In 1498, Machiavelli was appointed secretary to the body of ten men chosen to direct the civil and military affairs of the government. This position, which was one of great importance, Machiavelli held for fourteen years, during which he was sent on a large number of foreign embassies. On the restoration of the Medici, in 1512, he was arrested on a charge of conspiracy, and put to the torture to induce a confession. He denied all knowledge of the conspiracy charged against him, but although released he was obliged for several years to withdraw from public life and betake himself to literature. After the defeat of the French by Charles V., at Pavia in 1525, Machiavelli was very active in arousing his countrymen to resist the advancing army of the Spanish emperor. In May, 1527, the Florentines again drove out the Medici rulers and proclaimed the republic; but Machiavelli was so distrusted by them that he was not allowed to take any active part in the movement for liberty. This disappointment, added to his already feeble health, brought on an illness of which he soon died. Machiavelli's writings comprised several volumes, his most important work being *Il Principe*, commonly called "The Prince." The purpose of this book is to reveal the means by which princes and rulers may maintain authority over their subjects; and the author boldly lays down the doctrine that in order to sustain their power rulers may use all possible means, including fraud and treachery. The principles taught in this book may be traced in a large measure to the peculiar nature of European politics in Machiavelli's time; but it nevertheless reveals a defect of moral sense in the author that is all the more to be deplored on account of his talents and great services to the state. See *Life*, by Villari; *Florentine History*, by Napier.

McKees'port, Pa., a city in Allegheny county, in southwestern Pennsylvania, the center of an extensive bituminous coal trade and commerce in natural gas, which abounds in the region. It is situated ten miles southeast of Pittsburg, on the Monongahela river at the mouth of the Youghiogheny, on the Baltimore and Ohio, the Pennsylvania, and the Pittsburg and Lake Erie railroads. It has a large number of manufacturing industries, among them being the largest wrought-iron pipe works on the continent, with ample capital and employing over 6,000 hands. There are establishments engaged in the manufacture of iron and steel, locomotives, railroad cars, glass works, lumber mills. The city also has a considerable river trade. Population, which has of late largely increased, 34,227.

McKen'na, Joseph, an American lawyer and jurist, was born at Philadelphia, Pa., Aug. 10, 1843. At the age of twelve he removed to California with his parents. He was educated at the college of St. Augustine, Benicia, studying law after his graduation and being admitted to the bar in 1865. He was soon after elected county attorney of Solano county, and in 1875 was sent to the state legislature. Although twice defeated for congress, he ran again in 1884 and was elected, serving four consecutive terms. During his life in congress he was an intimate friend of Mr. McKinley and assisted in the framing of the McKinley tariff (1890). He succeeded Judge Sawyer upon the circuit bench of the Pacific slope in 1892, appointed by President Harrison, and remained there until called by President McKinley to a seat in his cabinet as attorney-general. In 1897, he was appointed by the now deceased President to the vacancy in the supreme court, succeeding Justice Field.

Macken'zie, the largest river in British America. It rises as the Athabasca in British Columbia, flows over 600 miles into Athabasca lake and thence as the Slave river 240 miles to Great Slave lake. It now assumes the name

of Mackenzie river, and flowing northward in a course of 1,000 miles empties into the Arctic ocean. The Mackenzie received its name from Sir Alexander Mackenzie, by whom it was discovered in 1789. Sir John Franklin descended it in 1825.

Mackenzie (*ma-ken'zi*), **Alexander,** a Canadian statesman, was born near Dunkeld, Scotland, Jan. 28, 1822. He moved to Canada in 1842, engaging in business as a contractor until 1861, when he was elected to the assembly of Canada, remaining in the same until the formation of the Dominion parliament, to which he was also elected, representing the same constituency for 25 years. He was offered a seat in the Canadian cabinet in 1865, but declined it. Upon the resignation of Sir John Macdonald he became premier of the Dominion and minister of public works. Upon the election of a conservative majority to parliament in 1878, he, with his cabinet, resigned his position. At various times he visited his native country and was treated everywhere with distinction, being offered knighthood three times, but each time he declined the honor. He visited the queen at Windsor in 1881. Possessed of great ability as an administrator and of splendid gifts as an orator, his influence throughout the Dominion is still felt. He died at Toronto, April 17, 1892.

Mackenzie (*ma-ken'zi*), **Alexander Campbell,** musical composer, was born at Edinburgh in 1847. He studied music in Germany in his early years, and afterward at the Royal academy in London. After devoting many years to his art, in Edinburgh and in Italy, he was appointed principal of the Royal Academy of Music at London, and in 1892 became conductor of the Third Harmonic Society's concerts in London; and three years later he was knighted. His works embrace almost every form of music, his celebrity dating from the production of his opera *Colomba* at Drury Lane in 1883.

Macken'zie, Sir Morell, M. D., was born in 1837 at Leytonstone, England, and studied at the London Hospital Medical college, at Paris and Vienna. In 1863, he founded the Hospital for Diseases of the Throat, at London, and in the same year his essay on *Diseases of the Larynx* won for him the Jacksonian prize from the Royal College of Surgeons. Not long after, he was elected as assistant physician to the London hospital, then became full physician, and later was appointed lecturer on diseases of the throat, which appointment he held at the time of his death. He attended on the late German Emperor Frederick during his last illness. In 1888, Dr. Mackenzie published *The Fatal Illness of Frederick the Noble*, in vindication of his treatment. He was a corresponding member of the Imperial Royal Society of Physicians of Vienna and of the Medical Society of Prague, and an honorary fellow of the American Laryngological association. He was the author of a systematic treatise, in two volumes, on *Diseases of the Throat and Nose*, which has been translated into French and German, and is well known in America. He died at London, Feb. 3, 1892, after an illness of only a few days.

Mack'erel, an important food fish living in the North Atlantic from Cape Hatteras north to Labrador and Newfoundland. It is steel blue above with dark bars, and silvery beneath. They attain a length of seventeen or eighteen inches, or even longer; but the average length of those caught for the whole coast is about twelve inches. Their food is small crustacea, the spawn and young of other fishes, and jellyfish. They occur in large schools, and many vessels of fine modern construction are engaged in the mackerel fishery. They are caught with hooks and lines, and also with nets. They are salted and very extensively used as food. In a single year (1898) the market price of those landed at Boston and Gloucester amounted to nearly three million dollars.

Mackinaw or **Mackinac** (*mak'in-aw*), an island three miles long and two miles broad in the Strait of Mackinaw, which connects Lake Huron and Lake Michigan. The village of Mackinaw, on the island, is the seat of Mackinaw county, and is noted as a fashionable summer resort. Fort Mackinaw is situated on a rocky eminence, overlooking the village and commanding the strait. Population 564.

McKinley, William, twenty-fourth President of the United States, was born at Niles, O., Jan. 29, 1843. He was educated at public schools, the Poland academy, and Allegheny college. For a short time he taught school, but in the first summer of the Civil war, when still but eighteen years of age, he enlisted as a private in the 33d Ohio volunteer infantry. The next year he was made second lieutenant; the following year, first lieutenant; and captain in 1864. He was brevetted major by President Lincoln for gallantry in the field, March 13, 1865. He served on the staffs of Generals Rutherford B. Hayes, George Crook, and Winfield Scott Hancock. When mustered out, July 26, 1865, he was assistant adjutant-general, 1st division, 1st army corps. He began the study of law upon his retirement from military service; took a course at the Albany (N. Y.) Law school; was admitted to the bar in 1867, and settled at Canton, O., in

WILLIAM M'KINLEY.

the same year, which place has since been his home. Being elected to Congress in 1876, he served continuously in the house until March, 1891. As chairman of the committee on ways and means, he reported to congress the Tariff bill of 1890, known since as the "McKinley bill," taking advanced ground in favor of a high tariff. He was elected governor of the state in 1891, and re-elected in 1893. In 1896, he was nominated for President by the Republicans and was elected, receiving in the electoral college 271 votes, as against 176 cast for William J. Bryan. The issue for that year was for or against "free coinage of silver," Mr. McKinley opposing and Mr. Bryan favoring the same. The first year of his administration was marked by the stirring events and the diplomatic steps which led to the intervention of the United States on behalf of the oppressed Cubans. Early in the second year, war with Spain was declared (April 20, 1898). An army of 200,000 men was called out and speedily organized and equipped and the battles of the war were fought, beginning with the naval victory in Manila Bay, May 1st and closing with the surrender of the Spanish army at Santiago, July 14th. By subsequent treaty, Spain ceded to the United States Porto Rico and the Philippine Islands. A revolt of the Filipinos under Aguinaldo led to a protracted struggle which was not ended when the campaign for the succeeding presidential election occurred in 1900, and naturally this election turned largely upon the causes, the conduct, and the results of the war. Mr. McKinley was again elected President, November, 1900, a second time defeating Mr. Bryan, who was again the nominee of the Democratic party. Meantime the United States had taken a prominent part in the capture of Tien-tsin and Peking, China, relieving the legations without a declaration of war. The struggle in the Philippines was brought to a close early the next year and military rule was superseded by the establishment of civil government, July 4, 1901. In meeting the grave questions which arose during a period fraught with events of far-reaching importance to the nation, Mr. McKinley displayed high qualities as a statesman and political leader, and gained the esteem of men of all parties as a pure, able, and patriotic executive. While he was attending the Pan-American Exposition at Buffalo, an attempt was made on the life of President McKinley by an anarchist, Leon F. Czolgosz, during a public reception held in the Temple of Music in the exposition grounds, Sept. 6, 1901. Czolgosz took his place in the line of those who were shaking hands with the President, and, as he presented his left hand to the President, fired two shots from a pistol which he held in his right hand concealed by a handkerchief. One shot was not serious, but the other proved fatal. By prompt and skillful surgical attention, the dreaded result was for a few days averted, but the end came in the early morning of Sept. 14. The death of the beloved President and revered chief of the state, under such cruel circumstances, fell with instant and crushing effect upon the nation, and hushed to an awed silence its activities, and, for the time, even its life-breath. Foreign sympathy for the country's loss was also profound and widespread, for Mr. McKinley was held in high regard abroad, as he was widely, sincerely, and deservedly loved at home. His painstaking and tireless devotion to the duties of the executive office, his patriotism which was above all personal ambition, his wise guidance of the nation through grave perils to a height of prosperity before unknown, the purity of his personal character, the warmth of his friendship, and the courage and Christian resignation displayed in the closing hours of his life, combine to give to William McKinley an honored place in the records of the nation. His body was taken to Washington, where an impressive funeral service was held in the rotunda of the capitol, thence was carried to Canton, Ohio, where his burial occurred, Sept. 19, 1901.

Maclar'en, Ian. (See WATSON, REV. JOHN.)

Macleod (*mak-lowd'*), **Norman,** a minister of the church of Scotland, distinguished for his pulpit oratory and liberal Christianity, was born at Campbelltown, Argyllshire, June 3, 1812. He was educated at Glasgow university and was minister there until his death, June 16, 1872. His writings and sermons are at once charming and instructive, full of shrewd observation and good humor. His nature was large, and yet very childlike; manly, but full of tenderness and sympathy; and being very broad and catholic in all his views, his influence in the religious world was both widespread and beneficent. He published *Parish Papers*, *Wee Davie*, *The Starling*, and *Character Sketches*.

Maclise (*mak-lēs'*), **Daniel,** an eminent painter, was born at Cork, Feb. 2, 1806. He went to London in 1828, and entered the school of the Royal academy, where he won all the prizes for which he competed. In 1833, he made himself famous by his *All Hallow Eve*. His works are very numerous, and many of them have become quite familiar through engravings. *The Death of Nelson* and *The Meeting of Wellington and Blücher after the Battle of Waterloo* were admitted to be the finest mural paintings hitherto executed in England. He died at London, April 25, 1870.

Maclure (*mak-lūr'*), **William,** the "father of American geology," was born at Ayr, Scotland, in 1763, but settled in the United States in 1796. In 1803, he went to Europe as one of the commissioners to adjust the claims of American citizens against France for losses of property sustained during the revolution in that country. While in Europe he gave a great deal of attention to the geology of that continent, and on returning undertook a private

geological survey of the United States. He visited nearly every state and territory, crossing the Allegheny mountains a great many times on foot. At Philadelphia, he was long president of the Academy of Natural Sciences. He died near Mexico, in 1840.

McMahon (*mäk-mah-on'*), **Count Marie Edme Patrice Maurice,** ex-president of the French republic, was born at Sully, near Autun, Nov. 28, 1808. Entering the army at an early age, he saw active service in Algeria, especially distinguishing himself at the storming of Constantine, in the year 1837. He commanded the division that stormed the Malakoff at Sebastopol during the Crimean war, and in the Italian campaign of 1859 was created a marshal of France for the decisive part he took in the battle of Magenta. In the Franco-German war of 1870, he commanded an army corps, and although defeated and captured at Sedan, his military reputation remained untarnished. At the close of the war he was made commander of the army of Versailles, with which he suppressed the commune that held sway in Paris during many weeks. On the retirement of M. Thiers from the presidency of the republic, in 1873, Marshal McMahon was chosen his successor for a term of seven years, but resigned the position Jan. 30, 1879. He died at Paris, Oct. 18, 1893.

McMas'ter, John Bach, Ph. D., Litt. D., an American scholar and writer, was born at Brooklyn, June 29, 1852. He was educated in the public schools of New York, graduating at the College of the City of New York in 1872. Having first made a specialty of civil engineering, he was called to be instructor in the same in Princeton college, 1877, remaining there until 1883. In this year he was appointed professor of American history (to which study he had devoted his later years), at the University of Pennsylvania. His first published work, *Bridge and Tunnel Centres*, came out in 1876, but in 1883 he issued the first volumes of an important *History of the People of the United States*, the fourth volume of which appeared in 1895. The fifth volume did not issue from the press until five years later. He has also published a *Life of Benjamin Franklin; The Origin, Meaning, and Application of the Monroe Doctrine*, etc.

McMon'nies, Frederick William, an American sculptor, was born at Brooklyn, N. Y., Sept. 28, 1863. He studied art in the rooms of Augustus St. Gaudens, and subsequently pursued his course at Paris, London, and Munich. His best-known work was the great fountain in the principal court of the Columbian Exposition at Chicago. He also modeled the statue of Nathan Hale, which was erected in the City Hall park, New York, as well as several other public monuments. Among his later productions are the bronze doors and a statue of Shakespeare for the Congressional library, Washington, D. C. He received the Decoration of the Legion of Honor from the French government in 1896.

McNab', Sir Alan Napier, a Canadian soldier and statesman, was born at Niagara, Canada, Feb. 19, 1798. He served in the expedition against Sackett's Harbor in 1813; and later was in command of the English forces in their assault upon Plattsburg. At the close of the war he returned to Canada, studied law, and was admitted to the bar, residing at Hamilton. He was elected to the assembly of Upper Canada in 1830, subsequently becoming speaker of the house. During the insurrection of 1837–38 he was in command of the Canadian forces, with the rank of colonel. His energetic measures at that time soon dissipated the forces against him. He seized, burned, and sent over the falls the American steamer *Caroline*, which was engaged in conveying supplies to the rebels from the American side. After various further services, legislative and executive, being prime minister from 1854 to 1856, he died at Toronto, Aug. 8, 1862.

Ma'con, Ga., the capital of Bibb county, on the Ocmulgee river, in central Georgia, traversed by nine or ten lines of railway that interlace the state. It has many manufacturing establishments, representing various industries, the chief of which are those devoted to textile fabrics, together with a large commercial trade. It has many schools, churches, a public library, and is the seat of Mercer (Baptist) university, the State Academy for the Blind, the Alexander Free school, the Jones Home for Indigent Women, besides other educational and charitable institutions. Population 23,272.

Ma'con, Nathaniel, a North Carolina statesman, was born in Warren county, of that state, in 1757. He served as a private soldier in the Revolutionary war, and was a member of the state legislature from 1780 to 1786. He was a member of congress for twenty-four years, from 1791 to 1815, and of the United States senate for the thirteen following years, making a continuous service in congress of thirty-seven years, the longest on record. He died at his home in Warren county, N. C., June 29, 1837.

Macpher'son, James, a Scottish author, the alleged "translator" of the Ossianic poems, was born at Ruthven, Inverness-shire, Oct. 27, 1736. He was educated at King's college, Aberdeen, giving evidence of a taste for poetry while pursuing his course of study. In his 20th year he published a poem entitled *The Highlander*, and two years later published a small volume of fragments purporting to be translations of ancient Celtic poetry. These fragments excited so much interest that money was raised to send Macpherson on a tour through Scotland to collect more of the same. He accordingly visited the mainland and islands inhabited by the Gaelic

race, and in 1762 published "*Fingal*, with other poems composed by Ossian, and translated from the Gaelic," and this was followed the next year by "*Lemora*, with other poems, by Ossian." These poems were read with great interest, but a strong party soon arose to question their genuineness and the controversy over their authenticity has hardly yet ceased. Macpherson entered parliament in 1780, and sat as a member of that body for the next ten years. He died upon his estate in Inverness-shire, Feb. 17, 1796, his body being interred in Westminster Abbey at his own expense, and in accordance with his own request. See *On the Authorship of Ossian's Poems*, by Sinclair.

McPher'son, Gen. James B., was born in Sandusky county, O., Nov. 14, 1828, and graduated at West Point Military academy at the head of his class in 1853. In August, 1861, on account of his superior qualifications as an engineer, he was promoted to the rank of lieutenant-colonel and placed on the staff of General Halleck, commanding the department of the Missouri. In his capacity as staff officer General McPherson was with General Grant at Forts Henry and Donelson, at Shiloh, and at the siege of Corinth, rendering service that was gratefully acknowledged by that general; and during the Vicksburg campaign, in 1863, he commanded the 17th army corps which so successfully fought the battles of Raymond and Champion Hill. During Sherman's Atlanta campaign, McPherson commanded the army of the Tennessee, displaying the highest soldierly qualities in every engagement until he was killed in the battle before Atlanta, July 22, 1864. General McPherson was tall and rather imposing in appearance, but very gentle and unassuming in his manners, and his death was deeply lamented by all the officers and soldiers in his command. "To know him was to love him," was the high tribute paid to him by General Grant.

GENERAL M'PHERSON.

Macready (*mȧk-rē'dĭ*), **William Charles**, an English actor, was born at London, March 3, 1793. At an early age he was sent to Rugby to be educated for the bar, but his father's financial embarrassments forced him to adopt the stage as his profession. He made his first appearance as "Romeo" at Birmingham at the age of seventeen. Six years later, Sept. 16, 1816, he made his London début, playing "Orestes" at Covent Garden, and after several years of patient effort took rank among the leading English actors. In December, 1837, he inaugurated his famous Covent Garden management, during which he did much to improve and elevate the English stage. Macready made a number of visits to the United States, during the last of which a riotous mob, trying to break into the Astor place for the purpose of attacking him, was fired upon by the military and several lives were lost. Macready took his farewell of the stage at Drury Lane, Feb. 26, 1851, and passed his remaining days in retirement at Sherborne and Cheltenham; at the latter place he died April 27, 1873. As an actor Macready sought to combine the dignity of the Kembles with the naturalness of Kean. In addition to being an actor of great power, he was a man of fine literary taste and of pure, elevated character. See *Biography*, by Littleton.

Macrosporangium (*mȧk'ro-spo-rȧn'jĭ-ŭm*) (in plants). See MEGASPORANGIUM.

Macrospore (*mȧk'ro-spōr*) (in plants). See MEGASPORE.

Macrosporophyll (*mȧk'rō-spor'o-fĭl*) (in plants). See MEGASPOROPHYLL.

MacVeagh (*mȧk-vȧ'*), **Wayne**, lawyer and diplomat, was born near Phœnixville, Chester county, Pa., April 19, 1833. He graduated at Yale in 1853, and received the degree of doctor of laws from Amherst, 1881, and from the University of Pennsylvania in 1897. He was admitted to the bar in 1856, and three years later was elected district attorney of his native county, where he served till the outbreak of the Civil war. He was commissioned a captain of infantry in 1862, and major of cavalry in 1863. Mr. MacVeagh was appointed minister to Turkey by President Grant in 1870. In 1873, he was sent as the head of the commission intrusted by President Hayes with the duty of bringing order out of the political chaos of Louisiana. He became attorney-general in the cabinet of President Garfield, but resigned upon the inauguration of President Arthur. Mr. MacVeagh supported Grover Cleveland for president in 1892, and was sent by Mr. Cleveland as minister to Italy in 1893. For a number of years he was a prominent leader of the Civil Service Reform association of Philadelphia and a leader among independent Republicans. He was also an active member of the Indian Rights association.

Madagascar (*mȧd-a-gȧs'kar*), a large island off the southeast coast of Africa, from which it is separated by Mozambique channel. Madagascar is the third largest island in the world, reckoning Australia as a continent, being 975 miles in length, and its greatest breadth is 358 miles. Its total area is a little over 28,500 square miles. Madagascar consists of an elevated region in the center, from 3,000 to 5,000 feet above the level of the sea, and a nearly level country surrounding the

high land. The island is also surrounded with a belt of forest from 10 to 40 miles wide. The capital city, Antananarivo, is situated near the center of the island, and contains about 260,000 inhabitants. The chief ports are Tamatave, on the east coast. (population 6,000), and Majungà, on the northwest coast (about 250 miles distant from the coast of Africa), population 6,000. English missionaries first entered Madagascar in the year 1820, and were greatly encouraged in their work by King Radàma, but when Queen Ranavalona I. came to the throne, in 1828, a severe persecution followed, and they were compelled to leave. A great many native Christians were put to death, and Europeans generally were excluded from the island. But on the death of the queen, in 1861, there was a complete change in the policy of the government and since that time the people have made great progress in religion, as well as in all the arts of civilization. In 1879, all the African slaves on the island were set free, and considerable effort has been made to improve the military system and reduce the administration of law to a fixed and equitable system. In 1896, Madagascar, together with Nossi-Bé and Ste. Marie Islands, was proclaimed a French colony, though a French resident general had been received at the capital as far back as 1885. In February, 1897, the native queen was deposed by France and deported to the island of Réunion, and subsequently to Algiers. France now rules the island entirely, under a governor-general, aided by an administrative council. Many parts of the island are known to be rich in mineral ores. The chief exports are rubber, rice, hemp, and other fibres. The population of Madagascar is between 2,500,000 and 3,000,000.

Madeira (*ma-dē'ra*), an island belonging to Portugal, in the Atlantic ocean, off the northwest coast of Africa, about thirty-two miles long and from ten to fifteen miles broad. The island (area 505 square miles) is of volcanic origin, and is occasionally visited by earthquakes. It is traversed by a mountain chain running east and west; and the coasts are steep and rough, affording few harbors. Wine is the product for which Madeira has long been noted, several kinds of grapes being produced on the island. The vines were much injured by the grape disease in 1852; but they were soon replanted and only one failure of the crop has been recorded in the past twenty-five years. The value of the wine exported is nearly $1,000,000 a year. There is also a considerable export of sugar. The inhabitants of Madeira, estimated at 135,000 in number, are a mixture of Portuguese, Moors, and negroes, and are described as a vigorous, industrious, and peaceful race. The capital, Funchal (population 19,000), is the chief seaport, and a noted health-resort. Its situation is in lat. 32° 38′ N., long. 16° 54′ W. The Madeira islands began to be colonized by the Portuguese about the year 1420; they were occupied by the British in 1801, and from 1807 to 1814.

Madei'ra, a river of South America, and the largest tributary of the Amazon, is formed by the junction of the Mamoré and Guaporè in Bolivia, the Beni joining about 100 miles lower down. The river then flows northeast to the Amazon, its drainage basin embracing nearly 500,000 square miles. From its mouth to its first falls the distance is nearly 600 miles; and above this point navigation is rendered impossible by a series of falls and cataracts extending over 200 miles. The length of the river, including its tributaries, is about 2,000 miles.

Mad'ison, a city of Indiana, the capital of Jefferson county, is situated on the right bank of the Ohio river, 90 miles below Cincinnati and 50 miles above Louisville, Ky., with which two cities it has daily communication by steamer. Population 7,835.

Mad'ison, the capital of Wisconsin, is located in Dane county, on an isthmus between Lakes Monona and Mendota, 80 miles west of Milwaukee and at the junction of several railroads. The capitol, State university, and other public buildings stand on hills, commanding extensive views of beautiful scenery. The university is in a 13-acre park, is open to both sexes, has a faculty of 100 members and 2,000 students. It has an income of over $100,000, arising from a state tax of ⅛ mill on the dollar. The Washburn observatory, built in 1878–80, at a cost of $30,000, was given to it, with a full equipment, by Governor C. C. Washburn. Many summer visitors are attracted to this charming little city, by its pure springs, bass fishing, boating of all kinds, beautiful drives, and Chautauqua assemblies. It has also a large number of manufactories. Population 19,164.

Mad'ison, James, fourth President of the United States, his two terms extending from 1809 to 1817, was born at Port-Conway, Va., March 16, 1751, and graduated at Princeton college in 1772. He was elected to the Continental congress in 1780, and in 1784 to the legislature of Virginia, in which he was largely instrumental in securing the fullest religious liberty to the people of the state. He was also one of the leading spirits in the convention of 1787, which framed the constitution of the United States; and it was in a great measure due to his influence

JAMES MADISON.

that the instrument was ratified by the legislature of Virginia. Madison was a member of congress during Washington's administration; and although he retired to private life when John Adams became President in 1797, he was the author of the "Resolutions of 1798," adopted by the legislature of Virginia in opposition to the famous alien and sedition laws of the Adams administration. During Jefferson's administration, from 1801 to 1809, Madison filled the office of secretary of state with such ability that he was chosen Jefferson's successor and inaugurated President, March 4, 1809. The principal feature of his administration was the War of 1812 between Great Britain and the United States, which was terminated by the treaty of Ghent, Dec. 14, 1814, although the battle of New Orleans was fought on the 8th of January following. On retiring from the presidency, Mr. Madison took up his residence at Montpelier, Va., where he died June 28, 1836. While not distinguished for brilliancy of intellect or great oratorical powers, Madison was a pure and able statesman, and was well worthy of the universal respect accorded to him. See *Life*, by Adams; *Life and Times*, by Stoddard.

Madoc (*mād'oc*), a Welsh prince, who is believed by his countrymen to have discovered America three hundred years before Columbus. It is said that he sailed westward in 1170 with a small fleet, and, after a voyage of several weeks, reached a country whose inhabitants and productions were very different from those of Europe. After remaining for some time in this new country, he returned to Wales and equipped another fleet, with which he set sail and was never heard of again. The story of Madoc will be found in Lloyd and Powell's *Historie of Cambria*. Southey has made the legend the subject of one of his poems.

Madras (*ma-drās'*), the capital of southern India (Madras presidency), is on the coast of the sea of Bengal, which washes the eastern coast of the presidency about 225 miles north of Ceylon. It is the center of all the great military roads of India, is also the terminus of two railway lines, and is connected with a system of canals. Although it has not a single handsome street, there are several buildings of fine architecture and many spots of historical interest. Nearly all the most important offices and the headquarters of every department of the presidency are located here. The garrison of Madras is about 3,500 strong, of whom 1,200 are Europeans. Notwithstanding its exposed situation, Madras ranks third among the ports of India in the number and tonnage of vessels calling, and the value of its imports and exports. The port trades with every part of the world, exporting coffee, cotton, grain, hides, indigo, oilseeds, dyes, sugar, and horns, and importing iron and other metals and all kinds of European manufactures. The lighthouse, 125 feet high, can be seen from a ship's deck 15 miles at sea. The city of Madras dates from 1639. It is liable to be swept by furious hurricanes, which occur some years at the beginning of the monsoons in May and October. The present population is 452,518, about three-fourths of whom are Hindus. Over 50,000 are Mohammedans, 13,000 are Eurasians, and about 4,000 are Europeans. Madras presidency has an area of 141,189 square miles, with a population of 39,630,440. It comprises the eastern or Coromandel coast, a large part of the interior of the Deccan, and part of the western or Malabar coast. Its mountain ranges are the east and west Ghats, and it is watered by the Godavari, Kistna, and Kavari rivers.

Madrid (*ma-drid'* or *mā-drēd'*), the capital city of Spain, is situated on the left bank of the Manzanares, 880 miles by rail from Paris. It is built on a treeless plateau 2,000 feet above the sea level; and its sole recommendation as a capital would seem to be its central position in the peninsula. When Madrid was declared the capital of Spain by Philip II., in 1561, it contained about 30,000 inhabitants. At the beginning of the 19th century the population numbered 160,000; in 1860 it was 298,000, and in 1897 over 512,000.

Maelstrom (*māl'strŭm*), a famous whirlpool, or rather current, in the Arctic ocean, between Mosken and Moskerra, two of the Lofoden isles, on the northwest coast of Norway. Vessels can pass through this strait at high tide and low tide, although in one place there is always a rough sea, the water being churned into angry foam. The stories of ships being swallowed up are mere fables, although a ship fully under the power of the current might be dashed against the rocks on either side. The current takes twelve hours to complete a circular revolution.

Maestricht (*mās'trikt*), capital of the Dutch province of Limburg, in the Netherlands, 19 miles by rail from Liège, and 152 from Amsterdam. It lies on the left bank of the Meuse, a stone bridge connecting it with Wijk. It was formerly a fortress, but is now only a garrison town, the fortifications having been dismantled in 1871–78. Population in 1899, 34,620.

Mafia (*mā-fē'a*), a Sicilian order, or secret society, which gradually came to suppiant the authority of the state by its own decrees, which are enforced even at the cost of life itself. Its organization does not appear to be of a very definite nature; but its power is undoubted and pervasive. It controls elections, affords protection against the officers of justice, and practically renders it impossible for those not members of its order to secure employment upon the island. Boycotting, its usual weapon, is suplemented by violence whenever occasion may seem to demand it. Nearly all crimes of violence which occur in

any part of Italy are laid at its door, with how much truth in particular cases it is impossible to say. In the United States there is little doubt it has its own secret agents, as murders in the Italian quarters of our American cities are seldom traced to their real perpetrators, and the guilty parties are but rarely brought to justice. It was this state of affairs which led to the riot in New Orleans in 1890, when eleven Italian prisoners, incarcerated in the city jail upon suspicion of the murder of the chief of police, were taken from their cells and put to death by the mob. This act came near leading to the severance of diplomatic relations between Italy and the United States; but the difficulty was adjusted by the payment of a heavy indemnity to the families of the Italians that perished in the outbreak.

Magdale'na, the principal river of Colombia, South America, rises in Ecuador, about 2° north latitude, only eight miles from the source of the Cauca. These streams flow northward, one on each side of the central Cordillera range, uniting about 100 miles from the Caribbean sea, into which their waters are discharged. The Magdalena is navigable to Honda, 620 miles from its mouth, where the rapids begin; and above these it has been navigated to Neiva since 1875, a 20-mile railway alongside the rapids connecting the upper and lower portions of the stream. The length of the Magdalena is 1,050 miles, and the area of its drainage has been estimated at 92,000 square miles. Magdalena' is also a province or department of the republic of Colombia, and the seat of silver mines. It has an area of 24,440 square miles, with a population of 90,000; its capital is Santa Marta (population 6,000).

Magdeburg (*măg'de-bŏrg*), the capital of Prussian Saxony, and one of the chief fortresses of the German empire, is situated on the Elbe river, 90 miles from Berlin and 72 miles from Leipsic. Magdeburg was founded by Charlemagne in 805, and rebuilt by Editha, after its destruction by the Wends, in 924. During the Thirty Years' war it was besieged for twenty-eight weeks by Wallenstein in vain; but two years later (1631), it was taken by Tilly and burned to the ground, nearly the entire population perishing by fire or sword, or by drowning in the river. Magdeburg is at the junction of five railways, and its river trade is large. The city was taken by the French in 1806, but was restored to Prussia in 1814. It is the center of the German sugar trade, and has many manufactures, with a notable cathedral, which dates from the 12th century. Population (1900) 229,663.

Magellan (*ma-jĕl'lan*), **Ferdinand,** a Portuguese navigator, was born at Oporto about the year 1480. After several years' service in the Portuguese navy he visited Spain, and laid before Charles V. a scheme for reaching the Moluccas, or Spice islands, by sailing west, which was favorably received and acted upon by that emperor. Magellan sailed from San Lucas, Aug. 10, 1519, with five ships and about 250 men. Reaching the mouth of the La Plata river, and sailing along the coast of Patagonia, he passed through the strait that separates the island of Terra del Fuego from the mainland, and entered the vast ocean which he named the Pacific, on account of the smooth and tranquil waters that he found there. He continued his voyage across the Pacific until he reached the Philippine islands, which he at once proceeded to take possession of in the name of the Spanish king; but in an encounter with the natives of the island of Mactan, who resisted his authority and his efforts to convert them to Christianity, he was killed April 27, 1521. His only remaining ship, the *Victoria*, was brought back to Spain by Sebastian del Cano, who reached San Lucas Sept. 6, 1522; and thus was completed the first voyage ever made around the globe. See *Life*, by Towle.

Magellan, the name of the strait separating South America from the island of Terra del Fuego, and connecting the Atlantic and Pacific oceans. It is over 300 miles in length, its breadth varying from 10 to 15 miles. This strait was first discovered by Ferdinand Magellan, who sailed through it in the year 1520, and it has ever since borne his name.

Magenta (*mă-jĕn'tă*), an Italian town, 16 miles west of Milan by rail. Here on June 4, 1859, occurred the terrible battle between the French and Sardinians on one side and the Austrians on the other, in which the Austrians were defeated with a loss of 10,000 killed and wounded, besides 7,000 prisoners. For his part in winning this victory, Marshal McMahon was created by the emperor Louis Napoleon, duke of Magenta.

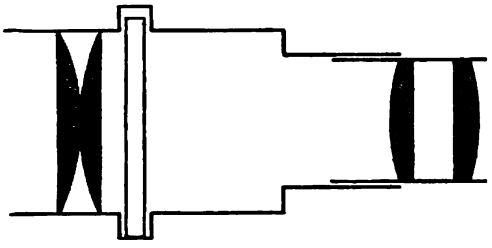
Maggiore (*măd-jō'rā*), **Lago,** one of the largest lakes in Italy, although the northern portion of it extends into the Swiss canton of Ticino. It is about 40 miles in length, and its breadth varies from one to five miles. It lies a little to the west of Lake Como, on the southern frontier of Switzerland. It is 600 feet above the level of the sea, its greatest depth being about 2,000 feet. On the north and west it is surrounded with granite mountains, and on the south and east, by vine-covered hills. It has some very picturesque scenery; on its banks are the Swiss towns Locarno, Intra, Pallanza, Luino, and Laveno.

Magi (*mā'jī*), the priestly caste among the ancient Persians. They were not only "keepers of the sacred things, the learned of the people, the philosophers and servants of God," but also diviners of the future, augurs, and astrologers. They were held in the highest reverence; and no transaction of importance took place without their counsel or advice. Zoroaster, in the course of his great religious reform, reorganized the Magi, sub-

jected them to the most rigid discipline, and prescribed a mode of life suitable to their sacred office. For a long time their influence was almost without limit, but it afterward declined until they became mere jugglers and fortune tellers, and gave their name (magic) to the tricks of conjurers and sorcerers.

Magic Lantern, an optical instrument mostly used by lecturers for projecting upon an opaque screen an enlarged and brilliant image of a picture or object otherwise too small to be seen simultaneously by an audience.

The ordinary magic lantern consists of five essential parts, as indicated in Fig. 1., namely:—



MAGIC LANTERN.

1. A source of light to illuminate the picture or object which is to be projected upon the screen.

2. A lens which collects the light from this source and trains it upon the picture or object. This is called the "condensing lens," or more briefly, the "condenser."

3. A "slide," that is, the picture or object which is to be shown to the audience.

4. A lens which will produce a good image of the illuminated slide. This is called the "projection lens."

5. A screen or wall—generally opaque and very white—upon which the projection lens casts the image which is to be viewed by the audience.

During the 17th and 18th centuries, this instrument was largely employed by magicians to produce certain curious effects for public entertainment. Hence the name "magic lantern," which is now largely replaced by the name *sciopticon*, or *stereopticon*.

The best source of light to employ is the electric arc; but when this is not available, the next best source is the "lime light." (See DRUMMOND LIGHT.) But the lime light requires a cylinder of coal gas and a cylinder of oxygen; and where these are not available an acetylene flame, or an oil lamp with two or three flames, makes a very fair substitute. Incandescent electric lamps of high candle power are now made for this special purpose.

The condensing lens is usually made up of two single plano-convex lenses with their spherical faces opposing each other. Since this lens is used only to throw light on the picture, and not to produce an image, it need be only a low-grade lens. Passing now to the "slide," it was the discovery of photography that led to the use of the lantern as a means of instruction rather than a means of amusement. The picture on the slide should be sharp so as to bear magnifying and clear so as to give a brilliant image.

The projection lens should be placed in a position between the slide and screen so that, when the slide is in one conjugate focus, the screen will lie in the other conjugate focus. It is necessary also that this lens should be of a rather high-grade—corrected both for chromatic and spherical aberration—since the definition of the image on the screen depends immediately upon this lens.

When the screen is viewed from the side on which the lantern is placed it should be as white and smooth as possible. And since it acts as a diffusing screen it is essential that no light should be lost by passing through the screen. It should, therefore, be filled with sizing or paint to make it opaque. See Wright's *Light* (Macmillan).

Magna Charta (*măg'nă kär'tă*), the great charter signed by King John of England, at Runnymede, June 15, 1215, which has ever since been regarded as the foundation of English liberty. Under the feudal system the tyranny and oppression of the Norman kings had become so great that, in the reign of King John, the English barons rose up against him and compelled him to sign this charter. By its provisions a great many abuses connected with the feudal system were abolished. Justice was no longer to be sold or denied to the subject. Life, liberty, and property were to be protected against the arbitrary will of the king, and no one was to forfeit either of these except by the law of the land. Fines imposed were to be in proportion to the offense, and even the humblest subject was not to be deprived of his lawful possessions. The great charter was renewed by John's successor, Henry III., in the ninth year of his reign and on five subsequent occasions before his death; and in the year 1300, it was finally confirmed by King Edward I. and his parliament.

Magne'sium, a widely distributed metallic element which is never found in the free state. It is present in many minerals, in carbonate of lime and magnesia, asbestos, meerschaum. It exists in mineral waters, and in the sea as a sulphate, and as chloride. A sulphate is Epsom salts, which Drew extracted from the Epsom spring in 1695. The metal was first discovered by Davy. For a long time its manufacture was on a small scale; but now it is made in large quantities. Chlorides of potassium and magnesium and fluor spar, with metallic sodium added, are fused together. The crude metal is finally distilled and pressed in a semi-fluid state into ribbon or wire. The metal is also prepared by passing an electric current through a fused

mixture of salts instead of using metallic sodium. It has a silver-white color, which is tarnished by moist air. It is very light, readily volatile, and when lighted burns in air with an intensely brilliant light rich in chemical rays. On this account it was much used in photography until the electric light took its place. The medicine calcined magnesia is the oxide of magnesium, the same substance as that formed when magnesium is burnt.

Mag'net, any mineral body that has the power of attracting iron or steel. A magnet may be natural or artificial, permanent or temporary. LOADSTONE is an iron ore that is very magnetic, and so forms natural magnets. The name comes from this property of drawing or leading bits of iron, "loadstone" meaning leading-stone. The first magnets used were pieces of this loadstone, which is a black mineral found very commonly in volcanic rocks and in beds with other iron ores. Large quantities are found in Sweden, and in the United States it is found in New York and New Jersey, and also in Asia Minor, near the town of Magnesium, from which magnets were named. Artificial magnets were first prepared by rubbing a bar of iron or steel with a magnet made from the loadstone. They are now made also by passing an electric current through a bar of iron or steel, or through a wire. The steel becomes a permanent magnet; the iron is only temporary, losing its power after the current ceases. Magnets can be made strong enough to hold up two tons, or two common loads of coal. A magnet's power of attraction is strongest at the ends, so that they are usually made in the shape of a horseshoe, which brings the two ends together. These ends are called the poles of the magnet, and while both poles will attract metals equally, they will act differently on other magnets. The north end or pole of a magnet will attract the south pole of another magnet, but will drive away the north pole, so that like poles repel each other and unlike poles attract. The poles are named north and south poles, because when a magnet is left free to move it will turn the same end always to the north and the other end to the south, as is seen in the mariner's compass. This is supposed to be due to the fact of the earth itself being a great magnet. This polarity, as it is called, is always found in magnets, and if you cut one in two there will be a north and south pole in each division. Steel magnets are made more powerful by placing several magnets together with their poles in the same direction. The magnet will not lose its magnetism by giving it to another piece of iron or steel, but it does lose it gradually if left alone. To avoid this, a piece of soft iron is placed across the two ends of the magnet, with a hook to which a weight can be attached. This piece of iron, called an armature, is thus turned into a magnet and receives the magnetism. By increasing the weight every few days, the magnet will grow stronger. Iron and steel are the substances most easily attracted by the magnet, but cobalt and nickel and some liquids and gases are also attracted by it. What magnetism is, is still undetermined; but it seems to be something in the atoms or particles of the magnetic body. The accepted theory is that it consists of two magnetic fluids in the body of the magnet adhering to the atoms, and that in a body not magnetized these two fluids counteract each other. Magnets made by electricity are called electro-magnets, and are used in the telephone, dynamo, etc. See ELECTRICITY, DYNAMO, TELEPHONE.

Mag'netism. It has been known for many centuries that a certain kind of iron ore, which mineralogists call *loadstone* or *magnetite*, has the remarkable property of attracting iron filings. A body which possesses this property is said to be *magnetized*, and is called a *magnet*. Certain parts of a magnetized body attract iron filings more strongly than others. These parts are called *magnetic poles*. A piece of iron can be magnetized by rubbing it over a piece of lodestone; and if the iron have a long, slender shape it will ordinarily have only *two* poles. The first important discovery in magnetism was made some time near the 12th century of the Christian era, when it was found that if a piece of magnetized iron be freely suspended it always sets itself so that a certain direction in it makes a fixed angle with the geographical meridian, *i. e.*, with the north-and-south line. This, of course, is the fundamental principle of the ordinary mariner's compass.

The direction in which the freely suspended compass needle points, at any place, is called the *magnetic meridian* at that place. The angle between the magnetic and geographical meridians is called the *magnetic declination.*

Before the time of Columbus first voyage to America, it was thought that the magnetic declination was a constant quantity. But on the voyage mentioned Columbus found that the declination varies from one point to another on the earth's surface. This was a discovery of the utmost importance to navigators. It might be called the second important discovery in magnetism.

Hartmann, who lived at a time intermediate between Columbus and Galileo, found that if a needle be suspended so as to lie *horizontal* before magnetization, it does not remain horizontal after magnetization; on the contrary, the north end "dips" down as if it had become heavier than the south end. This phenomenon is known as *magnetic dip;* and its discovery may be called the *third* important one in magnetism.

The first profound student of magnetism was Dr. William Gilbert (*b.* 1540; *d.* 1603), who was the leading man of science in England during the reign of Queen Elizabeth. He was led to conclude from the manner in

which small magnets behave at various points on the earth's surface that the earth itself is a gigantic magnet. But how the earth became magnetized is a problem which no one has yet been able to explain.

Gilbert showed also that when an iron magnet is heated to red heat, it not only ceases to be magnetized, but loses all ability to become magnetized. Red-hot iron behaves, therefore, not as cold unmagnetized iron, but as cold brass or glass or zinc. This discovery is described by saying that iron loses magnetic quality at red heat.

Gilbert also made it highly probable, by his experiments on broken magnets and on heated magnets, that magnetism is a molecular phenomenon, a prime discovery which all subsequent experiments have confirmed.

If, to the phenomena already described, we add that of *magnetic induction*, we shall have a fairly complete summary of the fundamental facts of magnetism. A piece of unmagnetized iron when brought near a magnet immediately acquires magnetic poles, *i. e.*, it exhibits magnetization as well as magnetic quality. A wire nail held near a strong magnet is not only attracted itself, but will also attract other iron nails or iron filings. These wire nails are said to be magnetized by *induction*. The most useful and most interesting case of induction met with in modern science is that of the *electro magnet*. Here an electric current is made to flow through a coil of wire in which is placed an iron core. This combination is called an *electro magnet*, and is a fundamental part of the dynamo, motor, telephone, and telegraph instrument.

Faraday made one of the great advances of modern times when he introduced into the study of magnetism the method of "lines of force," and the idea of the "magnetic field." For these and other more advanced considerations, see Ewing's *Magnetization of Iron and other Metals*, which is undoubtedly the best treatise on the subject in the English language. HENRY CREW.

Magno'lia, a genus of highly ornamental trees or shrubs, containing about 20 species, which are native to North America and eastern Asia. The finest of the American species, and the one most largely cultivated in the south, is *M. grandiflora*, which is native from South Carolina to Louisiana. In its wild state it reaches a height of 100 feet, and has very large thick leaves, the flowers being frequently a foot in diameter when flatly expanded. The other native magnolia in common cultivation is *M. glauca*, or "sweet bay," which reaches a height of about 30 feet.

Mag'pie, a bird of the crow family closely related to the jays, but distinguished by having a much longer and graduated tail. The true magpies are mostly inhabitants of the Old World. The American form is a variety of the European species, and occurs in the northwest from the Pacific coast east to Wisconsin. It is about sixteen or eighteen inches long, of black iridescent color, with white on

MAGPIE.

the under surface and wings. It is easily tamed and can be taught to articulate a few words. Its note is harsh, and it keeps up a continual chattering when disturbed. The food of the magpie is mainly snails, worms, frogs, rats, etc. Its nest is protected by rough thorns. These birds are noted for thievishness; they have a propensity to carry away and conceal bright articles, and, therefore, often steal jewelry. A great amount of popular superstition attaches to them. They were long regarded by superstitious people as birds of evil omen associated with witchcraft and the black art.

Magruder (*ma-grū'der*), **John B.,** an American soldier, was born Aug. 15, 1810, at Winchester, Va. At his graduation from West Point in 1830 he received an appointment as second-lieutenant in the infantry, becoming first-lieutenant six years later, and a captain at the outbreak of the Mexican war. He served throughout the invasion of Mexico under General Pillow, as the commanding officer of a battery. He was twice brevetted for bravery at Cerro Gordo, and again after the battle of Chapultepec, when he became lieutenant-colonel. He remained in the regular army until the breaking out of the Civil war, when he resigned in order to enter the Confederate force, in which he became a major-general. He took part in the battle of Malvern Hill, the fight on the Chickahominy, etc., but was afterward transferred to the southwest, being actively engaged in Texas at the time of the surrender of General Lee. He retired to Mexico where he accepted a commission as major-general in the army of Maximillian. Upon the collapse of the attempted empire he returned to Texas, lecturing in various southern cities. He died at Houston, Tex., Feb. 19, 1871.

Mag'yars. See HUNGARY.

Mahaffy (*mȧ-hăf'fi*), **John Pentland,** an Irish classical scholar and writer, was born in Switzerland, Feb. 26, 1839. He studied at

Dublin and in Germany, and became successively tutor, lecturer, and professor of ancient history in Dublin university. His works are mostly on subjects connected with his teaching, among them *Lectures on Primitive Civilization*, *Greek Social Life*, *Rambles and Studies in Greece*, *History of Classical Greek Literature*, *The Story of Alexander's Empire*, and *Greek Life and Thought*. He has edited Duruy's *Roman History*, and also translated Kuno Fischer's *Commentary on Kant*, and published Kant's *Critical Philosophy for English Readers*. Among his other publications are *The Decay of Modern Preaching*, *The Art of Conversation*, and the *Life and Teaching of Descartes*.

Mahan (*ma-hän'*), **Alfred Thayer,** a naval officer, was born Sept. 27, 1840, at West Point, where his father was a distinguished instructor in military engineering. He graduated from the United States Naval academy in 1859 and served throughout the Civil war, chiefly in the South Atlantic and Gulf squadrons. He was head of the department of gunnery in the Naval academy from 1877 to 1880, and president of the United States Naval War college, Newport, R. I., 1886–89. After various distinguished services rendered the republic in connection with naval commissions and educational institutions, he was appointed to the command of the United States cruiser, *Chicago*, and attached to the European squadron May 11, 1893. He soon became widely known for important works upon the history and philosophy of naval warfare and was exceedingly popular abroad, Cambridge conferring upon him the honorary degree of LL.D., and Oxford that of D.C.L. His writings embrace *The Gulf and Inland Waters*, *The Navy in the Civil War*, *The Influence of Sea Power upon History*, *The Life of Admiral Farragut*, *The Interest of the United States in Sea Power* and various other works, including a *Life of Lord Nelson*. Captain Mahan retired from active service in 1896, but was made a member of the Naval Advisory Board during the war with Spain, 1898, and appointed by the President one of the delegates to the peace conference at The Hague, 1899.

CAPTAIN A. T. MAHAN.

Mahanoy (*mä-ha-noi'*) **City, Pa.,** a borough in Schuylkill county, in the anthracite coal region, on the Lehigh Valley and on the Philadelphia and Reading railroads, 55 miles northeast of Harrisburg and 80 miles northwest of Philadelphia. It was founded in 1859, and has since developed greatly, due, in great measure, to the famous mines in its vicinity. There are in the immediate vicinity of the town about 20 collieries, giving employment to a large number of miners. Besides these mines, there are a number of iron foundries, potteries, etc. Population 13,504.

Mahdi (*mä'dē*), the Mohammedan restorer of all things. He is not mentioned in the Koran, but is said to have been promised by Mohammed to complete his work — to fill the world with righteousness. The Mahdi is a Mohammedan messiah. In Mohammedan history, at different times men of ambition have arisen who have set up claims to being the Mahdi. Hence the claim figures in war and strife between rival tribes and nations. In 1799, a Mahdi arose in Egypt against the French. Political exigencies have led men to set forth the claim. In 1883, one assumed the title of Mahdi and led a revolt against the khedive of Egypt. He seized El-Obeyd, the chief city of Kordofan, and made it his capital; and on the 5th of November the Egyptian army of Hicks Pasha was annihilated. In 1885, Khartum was taken, and General Gordon, whom England sent to pacify the Sudan, was killed. This Mahdi died at *Omdurman* on the 25th of June, 1885.

Mahog'any, the wood of *Swietenia mahogani*, which belongs to the family *Meliaceæ*. The tree becomes 70 feet high, and is native to Central America and the Antilles. Its beautiful dark red wood is chiefly used in veneering. The species of *Cercocarpus*, a genus of the rose family, is also popularly called mountain mahogany. There are four known species, which are found in the Rocky mountains from Montana to Mexico. The name is suggested by the very heavy and cross-grained wood.

Mahom'et. See MOHAMMED.

Mahone (*ma-hōn'*), **William,** a Confederate soldier and Federal senator, was born in Southampton county, Va., Dec. 1, 1826. His paternal ancestors were Irish, but long resident in America, and both his grandfathers served in the War of 1812. At the outbreak of the Civil war he entered the Confederate army, taking part in the capture of the Norfolk navy yard, April 21, 1861. Having been both student and instructor in military schools, he was rapidly advanced in the service

GEN. WILLIAM MAHONE.

and soon became colonel of the 6th Virginia infantry. He was engaged in all the desperate fighting about Petersburg toward the close of the war, and was called "the hero of the crater" on account of his bravery at the time General Grant exploded the mine under the earthwork popularly known by the Federal soldiers as "Fort Hell." This was July 30, 1864. He rose to the rank of major-general in the Confederate army. At the close of the war he returned to railway management in which he had been previously engaged and became president of the Norfolk and Tennessee road. He was elected to the United States senate in 1880, where, while nominally an independent, he usually voted with the Republicans. He retired from public life in 1889 and made his home at Petersburg, Va., where he died Oct. 8, 1895.

Mahrattas (*mȧ-rȧt'tȧz*), a people of mixed origin, who formed a famed and historic confederacy, Hindus in religion and caste laws, inhabiting western and central India. Our first knowledge of them in history is in the 17th century, when they possessed a narrow strip of territory on the west side of the peninsula. Their founder was a freebooter, Sivaji. He compelled several independent Hindoo chiefs to acknowledge him as their leader and with them overran and subdued a large portion of the territory of the emperor of Delhi. Under the fourth sovereign's reign there were five Mahratta states. The Delhi empire being invaded by Nadir Shah, the Mahrattas embraced the opportunity to snatch some more territory from the Mogul emperor. From this time they seemed to have discharged the office of arbiters between the emperor, his vizier, and his rebellious subjects. In 1761, they suffered a frightful defeat at the hands of the ruler of Afghanistan. They lost 50,000 men in this conflict. The growing influence of the British in India compelled them to give up serving as hired mercenaries in others' disputes, and to look out for their own safety. After many long and bloody contests with the British and their allies (1780, 1803, 1817–18), with the exception of Sindia, they were reduced to a state of dependence. Sindia officered his troops with Frenchmen, disciplined them after European methods and carried on the struggle with the British, till his power was broken in 1843. The son of the last reigning rajah, who became a British prisoner in the neighborhood of Cawnpore, was the infamous Nana Sahib, whose connection with the meeting in 1857 is historic. See INDIA.

Maimonides (*mi-mon'e-dēz*), **Moses**, a Jewish theologian, philosopher, and teacher, was born at Cordova, Spain, in 1135; and died at Cairo, Egypt, in 1204. His influence upon Judaism has been so important, that not without reason has he been classed as second to Moses himself. He brought into system multitudes of discussions, traditions, and decisions. He wrote an Arabic commentary on the Mishnah, and an historical introduction to *Tradition*. This introduction, translated into Hebrew, has now for more than 500 years been deemed so essential a part of the Talmud itself that no edition of the latter is considered complete without it. His greatest work, *Dalalt Al-Hairin* (Guide of the Perplexed), in Arabic, has been republished in three volumes by Friedlander in 1886.

Main, a river of Germany, the largest affluent the Rhine receives from the right. It mingles its yellow waters with the green current of the Rhine opposite Mainz (Mayence), after a zigzag course of 307 miles, the last 205 of which are navigable. It flows through a beautiful country. The hill slopes are generally covered with vineyards, and surmounted with castles. Its waters are joined to the Danube by a canal. The Main divides North Germany from South Germany. Frankfort is one of the chief cities on its banks.

Maine, the most eastern state of the Union, belonging to the New England group, admitted to the Union March 15, 1820. It has a long coast line on the Atlantic of 218 miles in a straight line, but is so indented by bays and islands that its shore measures 2,486 miles. On the east and north it touches New Brunswick, and on the west the province of Quebec. It is 303 miles long and 212 miles wide, and covers a land surface of 29,895 square miles, being one-half as large as New England. There are several ranges of mountains and some large peaks, as Mount Katahdin, 5,385 feet high; Mount Baker, 3,589 feet, and Saddleback mountain, 4,000 feet. The state has, besides its land surface, 1,568 lakes and ponds, Moosehead lake being the largest. The Penobscot, 270 miles long; the Kennebec, 155 miles, the Androscoggin and Saco are the principal rivers. The coast is a succession of islands and peninsulas and deep bays, forming what Whittier called "hundred-harbored Maine." The largest island is Mount Desert, covering 100 square miles, with thirteen mountains rising from the sea. This and other places on the coast and further inland are very popular summer resorts. The forests of Maine cover 20,000 square miles, and are seven times greater than the Black Forest of Germany. The fine trees of pine, elm, oak, and maple, etc., supply the great lumber trade of the state. The wild animals, such as deer, moose, caribou, wolverines, and bears, sables, minks, foxes, still found in the forests, give employment to hunters, and their skins furnish a large article of trade. Fishing is another industry, mackerel, lobsters, and herrings being collected in large numbers, and the waters of the rivers and lakes furnish ice in large quantities for shipment. Maine is rich in minerals; iron, lead, tin, copper, and zinc are found, and gold and silver in small quantities. Granite, felspar, mica, slate, and tourmaline are also found.

The granite quarries are very extensive, and lime is made on a large scale. There are also several good slate quarries. Much of the land of Maine has not yet been used for agriculture, but the Aroostook valley is the most fertile part of New England. Fruits are abundant, and the canning of fruits and vegetables is a large industry. The manufactures are boots and shoes, paper, leather, and flour. Its chief industries are cotton and woolen factories, pulp and paper, planing, shingle, and stave mills, canning and sardine-packing factories, with creameries, cheese, and starch factories. The state has a total railway mileage of 1,923 miles.

The State College of Agriculture and Mechanic Arts (University of Maine), at Orono, on the Penobscot, founded in 1868; Bowdoin college at Brunswick, opened in 1802, with a state endowment; Colby university at Waterville, Bates college at Lewiston, Bangor Theological seminary, Westbrook seminary at Deering, and Maine Wesleyan seminary and Female college at Kents Hill, are among the institutions of learning. Maine is thought to have been visited by the Norsemen in 900 and by Sebastian Cabot in 1497. The French made the first settlement in 1604, and Capt. John Smith, in 1616, took possession of Monhegan island. An English colony was formed on the Piscataqua river in 1623, and in 1639 Charles I. gave Sir Ferdinand Gorges a charter of the region between the Piscataqua and the Kennebec, under the title of the "province of Maine." Massachusetts claimed the region under her charter, and in 1677 bought out the interest of the Gorges, making it a part of Massachusetts until 1820, when Maine was admitted into the Union. There was a long dispute with Great Britain over the boundary line between Maine and the British possessions, which was finally settled in 1842. Maine has suffered in the past from emigration to the west, but its population is increasing by the immigration of foreigners, particularly the French Canadians and the Swedes. Population 694,466. See G. J. Varney's *Brief History of Maine.*

Maine, Sir Henry James Sumner, a celebrated lawyer of England, born Aug. 15, 1822, and died at Cannes, France, Feb. 3, 1888, of apoplexy. At the age of 25 he was appointed professor of civil law. In 1862, he went to India as law member of the council in India, an office held by Lord Macaulay. In 1877, he was elected Whewell professor of international law at Cambridge. Maine introduced wise reforms into Indian law, but his work on the origin and growth of legal and social institutions is the work on which his fame mostly rests. His publications include *Ancient Law, Village Communities, Early History of Institutions, Popular Government, International Law,* and *Dissertations on Early Law and Custom.*

Maintenon (*măn-te-nôn'*), **Francaise D'Aubigne,** Marquise de, was born in prison at Niort, France, Nov. 27, 1635. She was brought up in the West Indies, but returned to France in 1645. When she found herself at fifteen reduced to poverty by the death of her parents, the poet Scarron offered either to marry her or pay her entrance fee to a convent. He was lame and deformed, but she chose to marry him, and for nine years was the center of the intellectual society of his house. At his death his pension was continued to her, and in 1669 she was appointed governess of two of the sons of Louis XIV. At the death of the queen she was privately married to Louis XIV. Her influence over him was very great, and on the side of morality, and she was a liberal patroness of literature and art. She founded at St. Cyr a home for poor girls of good family, in memory of her own youth, and retired to it on the death of the king in 1715. She died at St. Cyr, near Versailles, April 15, 1719. See *Life*, by Bowles.

Maize. See CORN.

Majolica (*ma-jŏl'ĭ-kă*), a decorated kind of enameled pottery made in Italy from the 15th to the 18th century. It is an earthenware, usually of a coarse paste covered with a stanniferous (*i. e.*, affording tin) glaze or enamel. Sometimes it is called "Raffaelle ware," from the fact that a number of the paintings on it were copied from the designs of that famous painter. Majolica is generally considered the most beautiful decorated pottery that was ever extensively made, at least during the Christian era. It seems to have been first made on the island of Majorca, of which Majolica is the Italian name.

Majorca (*ma-jôr'kă*), the largest of the Balearic Isles; area, 1,310 square miles. In the north there are mountains from 3,500 to 5,000 feet in height. Olive groves abound everywhere, and almond, orange, fig, and other fruit trees are common. A London company, in 1871, drained 5,000 acres of marsh lands, which are of extraordinary fertility. Majolica is still made here to a small extent. Majorca, with Minorca and Ivica, all lying in the Mediterranean, off the coast of Valencia, form a province of Spain, called Baleáres (or in English the Balearic Isles); total area 1,860 square miles; population 306,926. The chief town of Majorca is Palma, on the southwest coast (population 62,525).

Malacca (*ma-lăk'ă*) or **Malay Peninsula,** is the long strip of land extending from Indo-China southward toward the island of Sumatra. The peninsula begins at the head of the gulf of Siam, and includes parts of Siam and Burma, covering 75,000 square miles. There are mountain ranges, covered with forests, running the entire length of the peninsula, with peaks from 6,000 to 8,000 feet in height. The camphor, ebony, teak, sandalwood, cinnamon, rattan, cocoa, and nutmeg

are the more valuable trees. It is the largest tin-yielding region in the world, and gold, silver, iron, and coal are found, though the mines are not much developed. The crops are rice, sugar cane, cotton, tobacco, yams, and cocoanuts. Population 1,200,000. Malacca is the name also of the British settlement in the southwestern part of the peninsula, and of the city which is its capital. In 1867, Malacca, with Penang, and the island of Singapore, were transferred from the Indian government of Britain to the control of the British secretary of state for the colonies, under the designation of the Straits Settlement, and erected into a crown colony. The seat of government is the town of Singapore. Christmas island and the Cocos islands have since been attached to the Straits Settlements.

Malacca, Strait of, a waterway or sea passage which separates the Malay peninsula from the island of Sumatra, and forms the channel between the Indian ocean and the Chinese sea. It is 480 miles in length, and from 30 miles to 200 miles broad.

Malaga (*mȧl'a-gȧ*), a seaport in the south of Spain, on the Mediterranean. It has a wonderfully equable and uniform climate, of which dryness and constant sunshine are the characteristics. It is one of the most important seaports of Spain, yet its trade has been declining since 1878. Diseases have ravaged the vines, the orange, and lemon groves. The United States, its great customer for Malaga raisins, now uses California raisins. Population 125,579. The town was founded by the Phœnicians; hence is very old. A Moorish castle is one of its few noted buildings. Ferdinand and Isabella captured it from the Moors in 1487.

Malay' Peninsula. See MALACCA.

Malays (*ma-lȧz'*), the race found in the Eastern archipelago and the neighboring peninsula, which are named from the Malay archipelago and the Malay peninsula. They belong to the Mongols, and are usually short in stature, being not much over five feet in height, with yellow skin, straight black hair, almond-shaped eyes, and flat features, resembling very much the Chinese. But their language is entirely different from that of the Asiatic Mongols; belonging to the great Polynesian family, which extends across the Indian and Pacific oceans. Since the 13th century the Malays have been the traders of the archipelago, and of late years have given up their roving habits, and are occupied with trade and agriculture. Their language is simple in structure, and soft and harmonious. It is written in the Arabic character, though lately the Roman system has been adopted. See *The Malay Archipelago*, by Wallace.

Malbone', Edward G., an American portrait painter, was born at Newport, R. I., in August, 1777. He began as a portrait painter when only seventeen, settling in Providence, R. I. He followed his profession afterward in Boston and Charleston, and in 1801, went to Europe with Washington Allston. *The Hours*, three female figures representing the Present, Past, and Future, is considered one of his best works. He died May 7, 1807, at Savannah, Ga., where he had gone in search of health.

Malcolm (*mȧl'kom*), **Sir John,** a British soldier, statesman, and historian, was born in Dumfriesshire, Scotland, May 2, 1769, and died May 30, 1833. At fourteen years of age he went to India as a cadet in the Madras army. In 1800, he was sent to Persia as an ambassador to form an alliance against Bonaparte. In 1803, he was appointed governor of a department in India. For years he occupied responsible situations for the British in India. The duke of Wellington wrote him in 1824, thus: "From the year 1796 no great transaction has taken place in the east, in which you have not played a principal, most useful, conspicuous, and honorable part." He wrote *A History of Persia*, *Memoir of Central India*, *Political History of India from 1784 to 1823*.

Malden (*möl'den*), **Mass.,** a busy and thriving manufacturing city, incorporated in 1882, on the Malden river, and the Boston and Maine railroad. It lies four miles north of Boston, and is the seat of many large industrial interests, chief of which are the Boston Rubber Shoe company, establishments for the manufacture of carpets and rugs, cotton goods, leather goods, boots and shoes, and shoe lasts, sand and emery paper, cord, etc. It has many substantial public buildings, libraries, schools, churches, banks, and other edifices. It does much for education in the extent and character of its public schools. Population 33,664.

Maldive (*mȧl'dīv*) **Islands, The,** lie off the coast of Malabar extending southward about 20 degrees of latitude, reaching an extreme length of 500 miles with an average breadth of 45 miles. The islands are composed of coral, and may be divided into 17 groups, each group or atoll being surrounded by a coral reef. It is estimated that there are 12,000 islands in the chain, of which 600 are charted and 200 inhabited. At no point does the surface of the land rise more than six feet above the sea, and the greater part of the surface exposed at low tide is covered when the tide returns. The population is estimated at from 20,000 to 30,000. The native races exhibit characteristic features of the Malays, the Singhalese, and Africans, and they are evidently a mixed race. The Portuguese, French, and Dutch, have at various times asserted authority over these islands; but they now constitute a dependency of Ceylon. The exports of tropical fruits are considerable; grain is also grown, and immense numbers of wild fowl frequent the archipelago. The

inhabitants live chiefly upon fish, rice, and cocoanuts. The people are at least nominally Mohammedans.

Male cell (in plants), the general name of the sperm or male gamete, which may take a variety of forms. The special use of the phrase, however, is in connection with the angiosperms, in which the cell which fertilizes the egg is unlike ordinary sperms in several particulars, and is usually called simply the "male cell" rather than "sperm."

Malibran (*mă-lē-brŏn'*), **Maria Felicita,** a famous operatic singer, was born at Paris, March 24, 1808. She made her début in London in 1825. Soon her reputation extended over Europe. At New York, she married M. Malibran, a French merchant, who became bankrupt. She returned to the stage, and was received with great enthusiasm in Italy, France, Germany, and England. Her marriage with Malibran being dissolved, she married M. Beriot, a famous violinist, in 1836, but on the 23d of September of the same year she died, at Manchester, England.

Mal'lard, a common wild duck inhabiting the northern hemisphere. It belongs to the group of river ducks, and is abundant in both the Old and New Worlds. The head and neck of the male are bright green and, therefore, it is commonly called the green-head. It is the original from which most of the domestic ducks are descended. In the western United States it visits cornfields, and in the southern Atlantic states, the ricefields. It is extensively hunted by the use of decoys, and its fine-flavored flesh makes it a favorite for the table.

Mal'lock, William Hurrell, an English writer upon religious and sociological themes, was born in Devonshire, England, in 1849. His mother was a sister to J. Anthony Froude, the historian. He graduated from Oxford, Balliol college, with honors. While still an undergraduate, he won the Newdegate prize by his poem entitled, *The Isthmus of Suez;* and his anonymous little poem, put out about the same time (1871), called *Every Man his own Poet*, attracted much attention. He wrote a large part of his *The New Republic* while still at the university, publishing it in completed form soon after his graduation, in 1876. His residence since has been changed from Oxford to London; again to the south of France and then back to Oxford. He has continued to publish works upon his favorite studies, among which are, *Is Life Worth Living? The New Paul and Virginia; Studies of Contemporary Superstitions; Social Equality; Property and Progress*, a reply to Henry George; *Labor and the Popular Welfare; The Old Order Changes; Classes and Masses, or Wealth, Wages and Welfare in the United Kingdom*, besides many others. His first purpose in nearly all his writings has been to expose the fallacies of socialism, and his secondary purpose to show that science cannot supply a basis for religion such as will suffice for the needs of man.

Mal'lory, Stephen Russell, a senator of the United States, 1851–61, was born in Trinidad, West Indies, in 1813, the son of a Connecticut shipmaster. He settled in Florida with his parents in 1820; was admitted to the bar in 1833 at Key West; was inspector of customs under Jackson; United States senator from 1851 to 1861; and at the outbreak of the Civil war entered the Confederacy, becoming secretary of the Confederate navy. After the war closed he was imprisoned; released on parole, and finally pardoned by President Johnson in 1867. He died at Pensacola, Fla., Nov. 9, 1873.

Mal'ory, Sir Thomas. Malory's work, a series of prose romances on the life and death of King Arthur and the knights of the Round Table, is immortal, though little of the author is known. The work is named *Morte D'Arthur*. Scott says, "It is indisputably the best prose romance the English language can boast of." He aimed to give epic unity and harmony to the whole mass of French romance. Caxton's edition of the work was finished in 1485. In the preface to this edition, we learn that Malory was a knight, and that he finished the work in 1470.

Malplaquet (*măl'plă'kā'*), a village in France, near the Belgian frontier, celebrated as the scene of the bloody defeat of the French under Marshal Villars, by the British and Dutch under the Duke of Marlborough and Prince Eugene, Sept. 11, 1709. The allied armies numbered over 1,000,000 men, and the French army somewhat less. The loss on each side amounted to about 20,000 men.

Malta (*mawl'ta*), an island in the Mediterranean, 58 miles south of Sicily. It is 17½ miles long and about 8 broad, and covers 95 square miles. It belongs to Great Britain, and is strongly fortified. It is the headquarters of the British Mediterranean fleet, and the chief coaling station for British vessels. There are several smaller islands (Gozo, Comino, etc.,) connected with it, belonging to England. Malta is treeless, and has no rivers or lakes, water being obtained from springs; but the soil is very fertile. There are several good harbors, and numerous odd caverns hollowed out by the sea, some of them quite large. The trade of the island is mainly one of transit; some 3,500 vessels enter and clear from the port annually, one-half of which are British. Wheat, potatoes, corn, barley, cotton, and the southern fruits are the principal products. Those of the people who are not engaged in agriculture are employed about the docks and harbors. The Maltese are a sober, industrious folk, fond of their home, called by them the "flower of the world." Their language is a dialect of Arabic, with a mixture of Italian, though the higher classes

speak English and Italian. The island is overcrowded with a population of 1,471 to the square mile, and large numbers of the people are obliged to emigrate, and are found in all parts of North Africa. There is a university, founded in 1769, with four faculties, and 120 public schools, with 15,669 in attendance. The cathedral of St. Paul, built in 1697, and the grotto of St. Paul, where the apostle is thought to have lived during his three months' stay on the island, as well as the bay of St. Paul, commemorate the apostle's shipwreck on his journey to Rome. The church of Musta, modeled after the Pantheon at Rome, has one of the largest domes in Europe. The capital of Malta is Valetta (pop. 50,000).

Malta was settled by the Phœnicians about 1000 B. C. The Greeks took possession about 700 B. C., the Carthaginians in 480 B.C., and the Romans in 216 B. C. Under the Romans it was famous for its cotton cloth, honey, and roses. Malta went with the eastern empire when the Roman kingdom was divided. In the 5th century, it was conquered by Vandals, and then by Goths, and in 870 the Arabs came into possession, but were driven out in 1090, by Count Roger of Sicily. Finally coming into the power of Charles V., he gave it to the Knights of St. John, who fortified it, making it very powerful. In 1798, the Knights surrendered the island to the French; but the people rebelled and succeeded after a two years' siege in driving off the French with the aid of the English. The people preferred the rule of Great Britain to that of the Knights, and the congress of Vienna in 1814 recognized Malta as a British dependency. Population 181,648. See *Malta, Past and Present*, by Seddall; and *The Story of Malta*, by M. M. Ballou (Boston 1893).

Mal'ta, Knights of, were a military and religious order of the middle ages. They were called also the Knights of St. John and Knights of Rhodes, and belonged to what were known as Hospitalers in the Catholic church, who were devoted to the care of the poor and the sick. The order was founded, about 1048, in a hospital built at Jerusalem and dedicated to St. John the Baptist. The order gradually became a military one, sworn to guard the holy sepulchre, and to war against unbelievers. Their last stronghold in Palestine was at Acre, which they yielded after a terrible siege by the ruler of Egypt and sailed to Cyprus in 1291. In the 12th century, the order was divided into eight divisions, called languages. After the capture of Rhodes and some neighboring islands by the Knights in 1310, they carried on from it a successful war with the Turks for more than two hundred years. Sultan Solyman took Rhodes from them in 1523, and they retired to Crete. In 1530, they received Malta as a gift from Charles V., which they yielded to the French in 1798. After the Reformation they declined in importance, and most of their lands were confiscated by the different European states. There are two or three branches of the order still existing, and two modern associations, one of which, the English Knights of St. John, was the principal founder of the Red Cross society. The badge of the Knights of Malta was an eight-pointed cross of white, edged with gold, called the Maltese cross, and their motto was "Pro fide" (for the faith), and later was added "Pro utilitate hominum" (for the good of man).

Mal'thus, Rev. Thomas Robert, an English clergyman and writer on political economy, was born at Albury, County of Surrey, England, in 1766. He entered Jesus college, Cambridge, in 1784, and graduated with high honors four years later. In 1797, he received a fellowship at Cambridge. He became rector of a small parish in Surrey, soon after receiving holy orders, and he divided his time between his ecclesiastical duties and his philosophic studies. It was in 1798 that he issued the work which made his reputation and by which he has since been known, an *Essay upon the Principles of Population as It Affects the Future Improvement of Society*. The leading idea of this work is that the population of the earth increasing steadily in geometrical ratio, the world must soon be over-populated; and that unless means to check such increase be promptly adopted, the nations of the earth must soon be brought to the verge of starvation. Neither war, pestilence, nor famine has as yet sufficed, he thought, to avert the sure catastrophe awaiting the race. He insisted that abstinence from marriage could alone keep down the threatened overplus of population. He himself married in 1805, and was the same year appointed professor of history and political economy in the East India college at Haileybury. Malthus also published *Observations on the Effects of the Corn Laws*, *Principles of Political Economy*, and *Definitions in Political Economy*. He died at Bath, Dec. 23, 1834.

Mal'vern Hill, Battle of, the last of the battles of McClellan's memorable Peninsular campaign. The hill is situated near the James river, Virginia, southeast of Richmond. After the battle of Gaines' Mill, June 26, 1862, when the Federals were driven back with heavy loss, McClellan began a retreat to the James river. His left wing, which was south of the Chickahominy, led the way through White Oak swamp. His right wing, which was north of the Chickahominy, was with difficulty withdrawn across that stream, and following through White Oak swamp was attacked by Lee at Savage Station and again at Frazier's Farm, where desperate battles were fought June 29 and 30. Then General McClellan reached Malvern Hill, on the north bank of the James river, where he secured a strong position. Massing his artillery he repelled

the attack of the Confederates July 1, with great slaughter. Again and again their columns were hurled forward only to be mown down by the Federal guns. The next day McClellan withdrew to Harrison's Landing, and the "seven days' fight" was at an end. McClellan's losses, including killed, wounded, and missing, were 15,849; Lee's were 19,749. But McClellan had lost the campaign, the attempt to capture Richmond had failed.

Mamelukes (*mam'e-lūks*), the Arabic word for white slaves, and especially the name of the slave kings of Egypt. They came from a body of Turkish slaves, brought in the 13th century from Asia Minor and the Caucasus, to act as the mounted bodyguard of the sultan of Egypt. On the death of their master they chose one of their own number his successor in 1250, and from that year to 1517 the Mamelukes ruled Egypt and Syria. There were forty-eight Mameluke sultans, often keeping the throne but a few years or months, in two royal houses, the Turkish and Circassian Mamelukes. Each sultan owed his throne to his courage and ability, and to his having the strongest battalions back of him. Each great lord was a little sultan on his own estate, with his bodyguard, ready on the first chance to fight his way to the throne. Violent and treacherous deaths were common, yet Egypt, since the Pharaohs, did not possess a more enlightened set of rulers than the Mamelukes. Their laws and police, their army, their naval enterprise, their postal service, their irrigation and engineering works, were all far ahead of their time. Most of the beautiful mosques of Cairo are of their building. Their brass work, wood carvings, ivory reliefs, tiles, mosaic pavements, and silk embroideries are all remarkable. Their dress, homes, and court were gorgeous. Turks as a rule, they had tastes beyond the right of the Ottoman Turk who conquered Egypt in 1517. The Ottoman pasha, who now ruled, allowed twenty-four beys to rule the provinces. These beys, all Mamelukes, soon got all the power, and the pasha became a cipher. Their last brilliant achievement was their desperate charge on Napoleon's squares at the battle of the Pyramids in 1798. Soon after Mehemet Ali came to power, and, by two treacherous massacres in 1805 and 1811, blotted out the Mameluke princes, except a few who fled to the Sudan. See S. Lane-Poole's *Art of the Saracens in Egypt*.

Mamma'lia, the highest class in the animal kingdom, including all those forms with breasts (*mammæ*) by means of which they suckle their young. The group is a varied one and contains animals ranging in size from the smallest harvest mouse to whales nearly one hundred feet long. They are all air-breathers, those forms living in the water like whales, sea-cows, and seals come to the surface to breathe. The lungs and heart are in the thorax, which is cut off from the abdominal cavity by a partition—the diaphragm. They all have a four-chambered heart, a complete circulation, and red blood corpuscles without nuclei. They all possess hair at some stage of their life on some portion of the body. Even the young whales have hairs that disappear in the adult, or are confined to the snout. This covering is variously modified; it may be fine fur, wool, long coarse hair, or developed into sharp spines as in the porcupine, spiny ant-eater, and others. The outer part of the horns of ruminants is believed to be modified hairs, and the horn of the rhinoceros is regarded by many anatomists as made of compacted hairs. The other parts derived from the outer cell-layer, like claws, hoofs, the plates of the armadillo, etc., if not modified hairs are equivalent structures. The bony system of mammals is well developed. The skull articulates by two processes with the vertebral column. There are usually two pairs of limbs, but in whales and manatees the hinder pair is lacking. The brain and sense-organs are highly developed. Most mammals live on dry land; the bats, however, have the power of flight, and other forms, like the flying squirrels and flying lemurs, make long leaps through the air. Whales, sea-cows, seals, and walruses live in the water. Squirrels and others live upon trees, and among the burrowers, belonging to this class, are moles, prairie dogs, rabbits, and others. An idea of the extent of the class will be obtained by naming the orders into which it is subdivided, and the common animals belonging to each order. There are three sub-classes, viz.: ORNITHODELPHIA, DIDELPHIA, and MONODELPHIA. The first contains a single order—the *Monotremata*, represented by the duck-bill and echidna of Australia. The second contains, likewise, a single order—the *Marsupialia* or pouched animals like the opossum, kangaroo, etc. The third sub-class is the largest and most important. It embraces twelve orders as follows: *Edentata*, toothless animals, like the armadillo, hairy ant-eater, etc. *Rodentia*, the gnawers, including squirrels, hares, the mouse, rat, beaver, and the like. *Insectivora*, the insect-eaters, like shrews, hedgehogs, moles, and other similar animals. *Chiroptera*, the bats. *Cetacea*, the whales and dolphins. *Sirenia*, the dugong and manatees. *Proboscidia*, elephants, the extinct mammoth, mastodon, etc. *Hyracoidea*, the conies. *Toxodontia*, an extremely curious group, containing some extinct forms—Toxodon and Nesodon—found in South America. *Ungulata*, a very important group of hoofed animals, containing the tapir, rhinoceros, horses, swine, camels, deer, cattle, giraffe, yak, goats, sheep, antelope, musk-ox, and a few others. *Carnivora*, the flesh-eating mammals, as bear, otter, raccoon, badger, mink, dog, fox, hyena, tiger, lion, lynx, walrus, seal, etc. *Primates*, the highest order embracing lemurs, monkeys, apes, and man. See *Mammals, Living and Extinct* (1891),

by Flower and Lydekker, and Schmidt's *The Mammalia.*

Mam'moth, a very large elephant-like animal now extinct. The bones of this animal are abundant in various parts of the

MAMMOTH.

world. Fortunately, also, some specimens have been found in northern Siberia in which the flesh, the skin, and other soft parts were preserved. At the close of the 18th century, a fisherman discovered in the frozen soil of the estuary of the river Lena, a perfect animal, and, in 1846, another was found in the same locality. Both were in a state of remarkable preservation. The skeleton of the one first discovered is now in the Museum at St. Petersburg. When living, the animal resembled the Indian species of elephant, but was larger. The body was covered with a dense short wool of a reddish-brown color; besides this, there was a covering of hair several inches long, intermingled with long black bristles. There was also a shaggy mane. This animal became extinct just before the beginning of historic times. It belonged to the latest epoch (Pleistocene) of geological time. There is evidence, in the form of rude pictures scratched on ivory, to show that it lived with primitive man in southern France, and likely elsewhere. The tusks were probably present in both males and females. They were curved, in some cases almost into a circle, and in the largest specimens discovered measured about twelve feet in length. The grinding surfaces of their great molar teeth were unlike those of any other elephant, having many more transverse ridges. They fed upon the shoots and cones of the fir and pine. Their geographical range was considerable — besides those found in Siberia they were abundant in England, in Central Europe, and in the northern part of America. Their teeth and tusks are so abundant as to supply a considerable amount of the ivory of commerce. For several centuries before the discovery of the mammoth, an active trade in their ivory had been carried on. Their skeletons have been washed out of the frozen soil and deposited again. Some of the islands on the coast of Siberia are said to be made largely of accumulations of their bones. See Haworth's *The Mammoth and the Flood.*

Mam'moth Cave, The, situated in Edmonson county, Kentucky, 85 miles southwest of Louisville. The cave is about 10 miles long, but it is said to take over 150 miles of traveling to explore its many avenues, chambers, grottoes, rivers, and falls. The main cave is only four miles in length, and is from 40 to 300 feet wide, and 125 feet in height. Lucy's dome is 300 feet high. Some avenues are covered with a continuous crust of the most beautiful crystals, and there are many stalactites and stalagmites. There are several rivers or lakes connected with Green river, outside the cave, rising with the river, but falling more slowly. The largest is Echo river, three-fourths of a mile long, and in some places over 200 feet wide. The air of the cave is pure, and the temperature remains always at about 54°. See A. S. Packard's *The Cave Fauna of North America;* also, his *Inhabitants of the Mammoth Cave.*

Man, Isle of, in the Irish sea, belonging to Great Britain. It has an area of 227 square miles, with a population of 30,000, is 33¼ miles long, 12½ miles broad, and covers 145,325 acres, of which nearly 100,000 are cultivated. At the southwestern end is an islet called the Calf of Man, covering 800 acres. A chain of mountains stretches from northeast to southwest. The coast scenery is bold and picturesque, especially at Spanish Head, the southern end of the island. Large quantities of lead and zinc are mined, and smaller quantities of copper and iron. The tailless Manx cat is the only animal peculiar to the island. The extensive herring and cod fisheries, cattle and wheat raising, are the leading employments.

Of the many interesting relics of Man, Castle Rushen, probably the most perfect building of its date extant, was founded by Guthred, son of King Orry, in 947. There are left about forty Runic crosses, besides other Runic monuments. Tynwald Hill, an artificial hill, arranged in four platforms, where new laws were proclaimed, goes back to the time of the Scandinavians. The chief towns are Castletown, Douglas the modern capital, and Peel. Little is known of the Isle of Man before the 6th century. From that time it was ruled by Welsh kings till near the end of the 9th century, when the Norwegians conquered it. Scandinavian kings were in power till it and the Hebrides were ceded to Alexander III. of Scotland in 1266. After his death, the Manx placed themselves under the protection of Edward I. of England in 1290. Royal favorites governed it until 1406, when it was bestowed on Sir John Stanley and his heirs, who ruled at first as kings and afterward as lords of Man. To stop the smuggling trade carried on, the English government bought the sovereignty of the island in 1765.

The Isle of Man has a constitution and government of its own, somewhat independent of the English parliament. Its legislature,

called the Court of Tynwald, is made up of the council, and the house of Keys, or representatives chosen by the people, including women. A bill must pass both houses, be assented to by the crown, and even then is not a law till it has been proclaimed in the English and Manx languages on Tynwald Hill. The Manx are a Celtic people with a mixture of Scandinavian. The language is Celtic, but is little spoken. See Rev. J. G. Cumming's *Isle of Man;* also Scott's *Peveril of the Peak.*

Managua (*mä-nä'gwä*), capital of Nicaragua, lies in a fertile district on the south shore of Lake Managua. Population about 25,000.

Mana'gua Lake, Nicaragua, at the head of which the city of Leon, once the boast of Spanish America, was founded in 1523. It lies twelve miles northwest of Lake Nicaragua, with which it is connected by a small stream.

Manas'seh, the eldest son of the patriarch Joseph. The tribe of Manasseh was given land on both sides of the Jordan. Manasseh was also the name of the fourteenth king of Judah, who succeeded his father Hezekiah, in 697 or 699 B. C., at the age of twelve, and reigned 55 years. He rushed headlong into all manner of idolatry, and led the people with him. Carried prisoner to Babylon, he repented, and his prayer was heard.

Manatee (*măn'ă-tē'*), an aquatic mammal found along both shores of the Atlantic in tropical regions, and also in the large rivers. There

MANATEE.

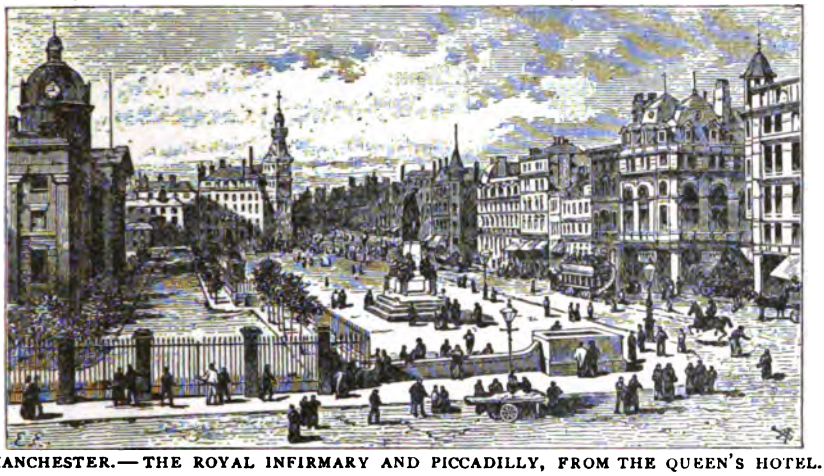
are three species known, and they all go under the name of sea-cows. One species lives on the west coast of tropical Africa, one on the eastern coast of South America, and the third on the Florida coast. The South American form is the best known; it extends to the West Indies and the gulf of Mexico, and is, possibly, the same as the Florida species. It has a long body with a broad oval tail. There are no hind limbs, but the front, flipper-like limbs are managed with much dexterity, and it was from this that it received the name of manatee. The skin is grayish in color with sparse hairs. The manatees are slow-moving, mild, inoffensive creatures, passing their whole life in the water, but, of course, coming to the surface to breathe. They are not found in the high seas, like the whales, but live along the shores in bays, estuaries, lagoons, and large rivers. They live equally well in salt and fresh water, and ascend the Amazon to Peru and Ecuador. They feed upon water grasses and marine algæ. Their size has been greatly overstated—about eight feet is the length now given by the best authorities (Flower and Lydekker). They are hunted by the Indians for their flesh. They yield also a soft, clear oil.

Man'by, George William, inventor of life-saving apparatus for shipwrecked persons, was born in 1765, at Hilgay, in Norfolk, England. He served in the militia and became barrackmaster at Yarmouth in 1803. In 1808, he succeeded with his apparatus in saving the lives of the crew of the brig *Elizabeth.* This career of usefulness he followed for the remaining 46 years of his life. He died Nov. 18, 1854. Up to the time of his death nearly 1,000 persons had been rescued from stranded ships by means of his apparatus. He first invented a rope of rawhide which would stand the strain of being fired from a mortar, also shells filled with luminous matter, which, when fired, would enable the sailors to see the rope as it came. He also invented a kind of fireworks by which vessels could be seen from the shore on the darkest night.

Man'chester, a city in Lancashire, England, lies on the east bank of the Irwell river, 31 miles east of Liverpool. Sixteen bridges, besides railroad viaducts, join it to Salford, on the opposite bank, which is really a part of Manchester. Manchester is the center of the largest manufacturing district in the world. It is surrounded by a circle of suburban cities, and within a few miles there is a second ring of cities with populations ranging from 10,000 to 50,000. Thirty miles from Manchester is a third cluster of towns and cities, most of them engaged in manufacture. The present water supply is about 25,000,000 gallons daily, but of late a further daily supply of 50,000,000 gallons has been secured. The city government manages its own lighting, at a yearly profit of over $500,000. Manchester and Salford now have eleven parks, containing 300 acres. The free reference library contains over 250,000 volumes, and there are also six branch libraries. The Chetham library, founded in 1653, contains 30,000 volumes, many of them rare and very valuable. It was the first free library in England. The "Old Church," built in 1422, is a fine Gothic structure. The magnificent town hall is a Gothic, triangular building, costing $5,250,000. The hospital, the royal infirmary, was first used in 1755. Other buildings of note are the royal institution, the royal exchange, the free trade hall, and the assize courts. The statues of Wellington, Peel, Watt, and the Albert memorial, are a few of the many monuments of Manchester. The grammar school dates from 1515. Victoria university, and especially the Technical school, are well known.

Manchester was the first town in England to introduce, about the middle of the 18th

century, the factory system, where large numbers of men work together, in place of the older method of men working in their homes. In 1756, the Bridgewater canal was constructed, which joined Manchester to the coal fields of Lancashire, the salt mines of Cheshire, and made an outlet to the sea. In 1830, Manchester had the first perfect railroad in operation. In 1887–91, a great ship canal was built at a cost of $28,750,000, which has made Manchester an inland seaport. The canal was opened for traffic in 1894, and the revenue in 1898 derived from it was close upon $2,800,000. It is 35½ miles in length, 26 feet in depth, and 120 feet in bottom width. The width of the locks is 65 feet. There are about 700 different industries carried on, but the great business is cotton manufacture, and in and around Manchester are located two-thirds of the cotton mills of Great Britain and Ireland.



MANCHESTER.—THE ROYAL INFIRMARY AND PICCADILLY, FROM THE QUEEN'S HOTEL.

Manchester is mentioned as a Roman station, but was not known as a manufacturing district till the reign of Edward III. The famous Anti-Corn Law league, which after a seven years' struggle caused the repeal of the corn laws, began in Manchester. Population 548,000. See Saintsbury's *Manchester*.

Man'chester, the largest city of New Hampshire, stands mostly on the east bank of the Merrimac river, 59 miles northwest of Boston. The river here falls 54 feet, and affords water-power to many factories. It yearly manufactures nearly 100,000 bales of cotton cloth. There are also linen and woolen factories, shoes, edge-tool, locomotive, machinery, and carriage works. The main street is 100 feet wide; there are five public squares, and the streets are well-paved. The state reform school and a Catholic orphan asylum are located at Manchester. Population 56,987.

Mandalay (*măn'dă-lā*), the capital of Upper Burma, was founded in 1860. It was captured by the British in 1885. It is in the form of a square, each side a mile long, and is surrounded by a wide moat and a wall. The most famous building is the Aracan Pagoda, with a brazen image of Buddha visited by thousands of pilgrims. The great business is silk weaving. In 1886, a flood and a fire destroyed one-tenth of the city. Population, with cantonment, 188,815.

Man'derson, Charles Frederick, an American soldier, lawyer, and politician, was born at Philadelphia, Feb. 9, 1837. He removed to Canton, O., in 1856, and was admitted to the bar in 1859. In 1861, he entered the volunteer army as a private and rose through successive grades to the rank of brevet brigadier-general. He was in many of the battles of the west and was severely wounded at Lovejoy's Station, Ga. At the close of the war he settled down to the practice of law in Stark county, O.; but removed to Omaha, Neb., in 1869. He was city attorney of Omaha for a number of years and was elected to the United States senate in 1883, where he served until 1895, being president pro tem. of the senate in the 51st congress.

Mandolin (*măn'dō-lin*), a musical instrument somewhat like the lute. The body is made by gluing together narrow pieces of different kinds of wood. A sounding board, finger board, and neck like a guitar, are added. The sound is made by a plectrum. The finest kind is the Neapolitan mandolin, with four double strings.

Manetho (*man'ē-thō*), high priest of Heliopolis, Egypt, who lived in the 3d century B. C. At the request of the king, Ptolemy Philadelphus, he wrote a history of his country, which, as shown by comparing the fragments that remain with the monuments, was written from true sources. He divided the time from Menes to the conquest of Egypt

by Darius II. into thirty dynasties. This division has been followed by all historians of Egypt.

Man'fred, regent and king of Sicily, was an illegitimate son of the emperor Frederick II., and was born in 1231. At the age of nineteen he became prince of Tarentum, regent in Italy for his half-brother Conrad, and later regent in Apulia for his nephew Conradin. He was forced by the pope to flee to the Saracens, but returning defeated the papal troops and became in 1257 master of Naples and Sicily. The next year he was crowned king at Palermo, and soon conquered all Tuscany. But Charles of Anjou, brother of King Louis IX. of France, claimed Manfred's dominions as a gift from the pope, and at the bloody battle of Benevento, in 1266, Manfred was treacherously slain. His widow and three sons died in prison, where his daughter was kept for twenty-two years. His history is a favorite subject for plays and operas. See Byron's *Manfred.*

Manganese (*man'ga-nēz'*) is one of the heavy metals. It is reddish white in color and very hard and brittle. It rusts very rapidly in the air. Pure manganese is merely a chemical curiosity, but the metal forms several important alloys. It occurs in most iron ores and pig-irons to some extent. A kind of pig-iron, called *spiegeleisen*, contains from twelve to twenty per cent. of manganese, and a metal much richer in manganese is called ferro-manganese. These alloys are used in the manufacture of Bessemer steel and other kinds of cheap steel, for without manganese these steels could not be worked. An alloy of copper and manganese, manganese bronze, is valuable for certain purposes. Manganese occurs chiefly as carbonate and as the black oxide. The latter is important in the manufacture of chlorine gas. An artificial manganese salt, potassium permanganate, is largely used in chemical processes. Manganese gives a violet tint to glass, hence small quantities of manganese oxide are put into glass to neutralize the green color produced by the iron that is accidentally present.

Man'go, a fruit of the genus *Mangifera*, which contains 27 species of tropical Asiatic trees. *M. Indica* yields the common mango and is cultivated throughout the tropics. The fruit is kidney shaped, four or five inches long, with smooth, pale green to reddish skin, and a seed almost as long as the fruit, which has a rough and fibrous shell. In the tropics the mango is a staple article of food during the hot months, more than 130 varieties being cultivated in India alone. In some of the poorer varieties the pulp is full of fibre. The mango is extensively cultivated in the West Indies and more sparsely in southern Florida and California.

Mangosteen (*man'gō-stēn'*), the fruit of a species of Garcinia (*G. mangostana*), a native of the East Indies. The mangosteen is one of the best, and is said to be one of the most luscious of tropical fruits. It is about the size and shape of an orange, with thicker rind and similar pulpy segments. Its rind is purple outside, and the flavor is said to be something between a grape and a peach. It seems to be very difficult of cultivation except in the most favored situations. In the West Indies it is cultivated in Trinidad and Jamaica, but only in certain regions of these islands.

Man'grove, the ordinary name of species of Rhizophora, which are five or six in number and widely distributed in the tropics. The commonest mangrove is *R. mangle*, and is one of the most abundant plants of the swampy shores of tropical and subtropical seas. It is an important agent in the extension of land into the sea by means of aerial roots which are put out from the branches and dangle in the wind until they reach the mucky soil beneath the water, where they strike root and become rigid. The seed also germinates while the fruit is still upon the tree, so that the young plantlets drop like plumb-bobs into the water and at once set root. In both of these ways the mangrove gradually advances seaward, and the detritus caught by the interwoven stems and roots presently builds up land.

Manila (*mȧ-nĭl'ȧ*), the chief town of the Philippine islands, and capital of the late

Spanish possessions in eastern Asia, lies on a bay in the Island of Luzon, 650 miles southeast of Hong-Kong, with which it is joined by cable. A small river divides the city into two parts. Earthquakes, typhoons, and violent thunderstorms are frequent. A hurricane in 1882 ruined half the city. The great industry is cigar-making. The exports are mainly sugar, hemp, cigars and tobacco, and coffee. The population is about 350,000, mostly native Tagals, 25,000 Chinese, large numbers being descended from these two

races, and 5,000 Spaniards. Here, on May 1, 1898, the Spanish fleet was destroyed in the bay of Manila by the American fleet under Commodore Dewey, and the islands were ceded to the United States by treaty, Dec. 10, 1898.

Manil'la Rope. See ROPE.

Ma'nioc. See TAPIOCA.

Manistee (*măn-ĭs-tē'*), a city of Michigan, is on Lake Michigan, at the mouth of the Manistee river, and 135 miles northwest of Lansing. Manistee is noted for its manufacture of sawed and planed lumber and shingles, its production of the latter surpassing, as far as known, that of any other town in the world. The region is underlayed with a bed of salt 30 feet thick, and this gives employment to a large number of people in the ten salt-works. Manistee has gas works, three foundries, and a public water supply: while a branch of the Flint and Père Marquette railroad terminates here. It was incorporated in 1867. Population 14,260.

Manitoba (*măn-ĭ-tō-bă'*). The Canadian province of Manitoba (area 74,000 square miles), was formerly known as the Red River Settlement. It is situated in the center of the continent, and is bounded on the south by the 49th parallel; on the north by the district of Keewatin and Saskatchewan; on the west by the latter and by Assiniboia; and on the east by Ontario and the unorganized northeast territories of the Dominion. It has a population of 250,000, scant as yet for its wide and finely-productive area. The growth of its capital, Winnipeg, which stands on the site of Fort Garry, the scene of the Red river rebellion of 1869–70, and one of the posts of the Hudson Bay Fur company, has been extremely rapid, especially since the establishment of railway communication. The transcontinental line of the Canadian Pacific railroad, has been a great factor in this development, as has been that of the tract southward to Pembina, with its connection with the St. Paul, Minneapolis, and Manitoba railroad. In summer, steamers on the Red and Assiniboine rivers, on lakes Winnipeg and Manitoba, and on the lower Saskatchewan, add to the facilities of communication.

Manitoba entered the confederation in 1870, and, like the other provinces of Canada, has representatives in the Dominion houses of parliament. For its own affairs, it has a local legislature, with an executive of five ministers under a lieutenant-governor. Winnipeg (population 42,336), the capital, is the seat of government. The other chief towns of the province are: Emerson, Brandon, Birke, Minnendosa, Selkirk, Virden, and Portage la Prairie. Great are the extent and capabilities of what is proudly called "the Prairie province of the Dominion." The soil of Manitoba, having originally been the bed of a lake, is mainly formed of a rich silt, deposited during the æons of the past. Nowhere is such fine wheat grown as is grown in the province, and the average yield is high. Potatoes and other root crops also yield wonderfully. The climate is extremely healthy and bracing.

Besides the Scotch settlements, there are a number of Canadian-French, a colony of which is to be found at Saint Boniface, a suburb of Winnipeg. It was among the latter, chiefly trappers, Indian half-breeds, and French-Canadians attached to the fur companies, that rebellion arose in 1869–70, and again in 1885. The leader of the rebels was Louis Riel, a French Canadian, with Indian blood in his veins, who, resenting the acquisition of the northwest by the Canadian government, usurped authority in the region and formed a provisional government at Fort Garry. A military force, under Sir Garnet (now Lord) Wolseley, was dispatched to quell the rising; but, in 1885, having broken out again, Riel and his Indian half-breeds were hanged, and the country was restored to law and order.

Manitowoc (*măn-ĭ-tō-wŏk'*), **Wis.,** the capital of Manitowoc county, on the river of the same name, on the shores of Lake Michigan, 75 miles north of Milwaukee. It has a good harbor and a considerable lake trade, and is served by the Chicago and Northwestern railroad. Its industries consist of ship-yards, tanneries, edged-tool works, agricultural implement works, foundries, machine shops, and glue factories. It has good schools, churches, and a subscription library. Population 11,786.

Mankato (*măn-kā'tō*), a city of Minnesota, in Blue Earth county, is on the Minnesota river, 86 miles southwest of St. Paul; it is situated in a very fertile region. Steamboats can ascend the river to this point, and three lines of railroad pass through the city. The state normal school is located here, and there is a city hall, court house, sixteen churches, a Roman Catholic college, a public library, six weekly papers, nine hotels, and three banks. It manufactures tiles, flour, oil, woolens, wooden-ware, brick, cement, etc. The town is lighted with gas, and has a public water supply. It was settled in 1853 and incorporated in 1868. Population 10,599.

Mann, Horace, an American educator and reformer, was born at Franklin, Mass., May 4, 1796. He was graduated at Brown university in 1819, and began to study law. As a member of the state legislature, he founded the state lunatic asylum. In 1833, he became president of the state senate. For eleven years he was secretary of the Massachusetts board of education. He subsequently abandoned politics and business and gave his whole time to the cause of education, working generally fifteen hours a day. He became John Quincy Adams' successor in congress in 1848, where he opposed the extension of

slavery. He was president of Antioch college, Ohio, from 1853 till his death, Aug. 2, 1859. See his *Life*, by Mrs. Mann.

Man'na, a sugary substance obtained from the manna ash tree by making crosscuts into the stem. This tree is grown in Sicily and Calabria mainly for its sap, called manna. In July and August deep cuts are made near the base of the tree, and, if the weather is warm enough, the manna begins to ooze out of the cuts slowly and hardens into lumps or flakes. Manna is light and porous, in the form of crystals, easily broken, yellow in color, and with a sweetish, somewhat bitter taste. There are several other manna-yielding plants besides the ash, as the manna-bearing eucalyptus of Australia. The manna eaten by the Hebrews in their wandering in the wilderness was what is now called Mount Sinai manna, which falls to the ground from the branches of a kind of tamarisk. It oozes out through holes made in the bark by little insects. It is not true manna, but is a kind of reddish, sticky syrup, and is eaten by the monks of Mount Sinai like honey with their bread.

Man'ning, Henry Edward, Cardinal, was born July 15, 1808, at Totteridge, Hertfordshire, England. He was educated at Oxford, and soon came to the front as an eloquent preacher, and as leader of the well-known tractarian party in the English church. In 1851, he joined the Catholic church. He studied for a time at Rome, was made provost and then archbishop of Westminster. In the church council of 1870 Manning favored the doctrine of the pope's infallibility, which was then declared. He was made cardinal in 1875. Besides being foremost in most Catholic movements in England, he took part in many good works for bettering the social life of the people, such as the temperance movement, housing the poor, education, and the rights of workingmen. During the great strike of London dock-laborers he was the only man in England to whom the strikers would listen, and his arbitration of the strike made him, for the time, perhaps the most influential man in the country. A great churchman and a reformer, he was also an accomplished man of the world and scholar. Among his writings are, *Characteristics*, *The Catholic Church and Modern Society*, *Four Great Evils of the Day*, *Temporal Power of the Pope*, and *England and Christendom*. Cardinal Manning died at Westminster, Jan. 14, 1892.

Manometer (*ma-nŏm'e-tĕr*), an instrument for measuring fluid pressures. There are three principal types of manometers. The simplest type is merely a U-tube partially filled with mercury, and open at both ends. If now one arm of the U-tube be connected with the vessel in which the pressure is to be measured, the level of the mercury in the other arm will change; and the difference of level between the two arms *plus* the barometric height will give the pressure in the vessel. Water is sometimes used instead of mercury. This kind of manometer is shown in Fig. 1.

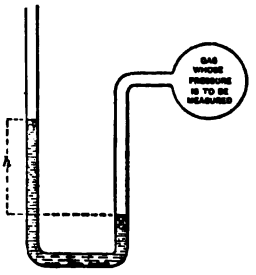


FIG 1.

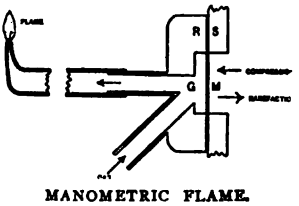
The *second* type of manometer is one in which a U-tube is also employed — but a U-tube with one end sealed off and inclosing a definite amount of gas. The open end being connected with the vessel in which the pressure is to be measured, the volume of the gas inclosed in the other end is changed. And, by use of Boyle's Law, the pressure may be computed as soon as the volume of the inclosed gas is known. Lord Kelvin's deep-sea sounding apparatus is merely a manometer of this type by which the pressure at any point in the sea is measured. From this pressure, the depth of the sea is computed.

A *third* type of manometer is the one commonly employed on steam boilers and known as a *pressure gauge*. This device consists of a flattened and curved metallic tube which changes shape as the difference of pressure between the inside and outside is changed. It was invented by Bourdon and is frequently called a *Bourdon gauge*. See article ANEROID BAROMETER. One end of this gauge is fixed, while the other end is free to move an index which shows the pressure on a graduated dial.

Manometric (*man'o-mĕt'rik*) **Flame,** an instrument for exhibiting to the eye the disturbances which a sound produces in the air, was invented and perfected by Rudolph König of Paris. In the figure, R and S represent two blocks of wood which have been bored out. A diaphragm of goldbeater's skin is clamped between these two blocks and thus divides the whole apparatus into parts. Illuminating gas is admitted to the left-hand side of the apparatus as indicated by the arrows, and burns with a quiet flame so long as the diaphragm is undisturbed. If, however, the air on the right of the diaphragm is suddenly compressed, the flame will flare; and if this air is suddenly rarefied the flame will for an instant burn low. The effect of a sound wave striking this diaphragm is then to drive it alternately forward and backward, making the flame pulsate. These acoustical disturbances are, however, so rapid that the changes in the height of the flame are not



MANOMETRIC FLAME.

easily seen. Accordingly, the flame is generally observed in a rotating mirror, which serves to separate the images of the flame at successive instants. In practice, the block, S, is generally provided with a mouthpiece or with a tube to lead the sound up to the diaphragm, M. This instrument is used to exhibit, in the most beautiful manner, the qualities of various sounds, as, for instance, the difference in the various vowels pronounced by the same voice.

Mans'field, a city in the central part of Ohio, 65 miles northeast of Columbus. It is situate in the midst of a fine farming country, on an elevated site. It has a large trade, and manufactures threshing machines, woolens, paper, boilers, carriages, furniture, and flour. It is the home of Senator Sherman. Population 17,640.

Mans'field, Richard, an actor, was born on the island of Heligoland, May 24, 1857. He first appeared as a musician in Liverpool in 1877, and for some years after that was seen only in small parts in comic operas. His first marked success was achieved in New York at the Union Square theatre in January, 1883, as the "Baron de Chevreul" in a Parisian romance. Three years later he appeared as a star in the Madison Square theatre, New York, in *Prince Karl*. Later he took the part of "Dr. Jekyll and Mr. Hyde," in the dramatized form of that well-known work. On Sept. 12, he appeared at Daly's theatre, New York, in *The Scarlet Letter*. He appeared as "Cyrano de Bergerac" in 1899.

Mans'field, William Murray, Earl of, lord-chief-justice of England, was born at Perth, Scotland, March 2, 1705. He graduated from Oxford in 1730, and after studying for the law, he soon secured a large practice, chiefly because of his force as a speaker. In 1743, he was made solicitor-general, and entered the house of commons, where he took high rank. He was consul against certain rebel lords in 1764, appointed chief-justice in 1756, and the same year became a member of the house of lords and of the British cabinet. Although he was fair in his decisions as head of the king's bench, his opinions were not on the popular side, which abused and hated him. The famous then unknown Junius attacked him, and during the Gordon riots of 1780 his house, with all his books and papers, was burnt. He would not allow parliament to repay his loss. He died at London, March 20, 1793. See Campbell's *Lives of the Chief-Justices*.

Man'son, George, a Scottish water-color painter, was born at Edinburgh, Scotland, Dec. 3, 1850. For five years he worked as a wood engraver, studying art in his spare hours morning and evening. His first noted picture, *Milking Time*, was painted between four and eight o'clock in the mornings of a whole summer. Hard work and study ruined his health, and he died in Devonshire, England, Feb. 27, 1876. His pictures are mostly from common life and are charming for their beauty of drawing and color. See P. G. Hamerton's *Graphic Arts*.

Mantegna (*măn-tăn'yȧ*), **Andrea,** an Italian historical painter, was born near Padua, Italy, in 1431. He was the adopted son of a tailor in whose house he studied the collections of ancient paintings and sculpture which he took as his models. He did not aim at grace and beauty, but at dignity and truth, and some of his pictures are even ugly. His genius showed itself early, and he was but seventeen when he set up a studio. His early paintings were frescoes of saints and altar-pieces for churches. In 1459, he made his home in Mantua, though making a visit to Rome to paint frescoes for Pope Innocent VIII. His masterpiece is a series of nine pictures showing the *Triumphs of Cæsar*. Others were *Parnassus*, *Defeat of the Vices*, and *Triumphs of Scipio*. Mantegna was also an engraver and architect, and is said to have been a poet and sculptor. He had great influence on Italian art. He died at Mantua, Italy, Sept. 13, 1506.

Manteuffel (*măn-toif'fel*), **Edwin Hans Karl, Freiherr von,** a Prussian general, was born at Dresden, Feb. 24, 1809. He entered the army in 1827 and became head of the military bureau at Berlin in 1857. Having been made commander of the Prussian troops in Sleswick, he marched into Holstein in 1866 to prevent the summoning of the estates. He took part in the battle of Langensalza, which brought about the surrender of the Hanoverian army. As commander-in-chief of the army of the Main, he won the battles of Werbach, Tauberbischofsheim, Helmstadt, and Rossbrunn over the Bavarians and others, the south German allies of Austria. As commander of the first army, he fought successfully at Amiens and other places in the war of 1870. In 1871, Manteuffel attacked the French near Belfort and drove 80,000 men across the frontier into Switzerland. In 1879, he was made viceroy of the conquered provinces of Alsace and Lorraine. He died at Karlsbad, Bohemia, June 17, 1885.

Mantua (*măn'tū-ȧ*), a fortified city of northern Italy, and formerly the capital of the duchy of Mantua, is on two islands formed by the Mincio river. The marshy district around it, and its fortifications, make it perhaps the strongest fortress in Italy. It has broad streets and many open squares. The fortress of the Gonzagas, adorned with paintings by Mantegna, the cathedral of San Pietro, and the church of San Andrea, are its chief buildings of interest. Virgil was born at Pietole, now a suburb of Mantua. Mantua was first an Etruscan town, then it belonged to the Romans, Ostrogoths, and Lombards. The Gonzaga family became its rulers in 1328, and

not only maintained themselves against their great rivals, the Visconti of Milan, but raised the city to the height of its splendor and renown. Mantua became a part of Austria in 1708, who held it till 1866, except for two short periods, when it was in the possession of France. In the latter year, it was ceded to Italy. The city has had three great sieges — by the emperor Ferdinand II. in 1630, by the French in 1797, and by the Austrians in 1799. Population 30,217.

Man'ual Training in Public Schools. In 1868 Victor Della Vos, director of the Imperial Technical school for government engineers at St. Petersburg, conceived the plan of teaching certain kinds of tool-work by means of models and drawings and practice exercises, before any attempt should be made at the execution of trade-work. The exhibition made by his school at the Centennial exposition in Philadelphia, in 1876, directed the attention of American educators to a system which it was felt could be made of inestimable value to the young people of the United States, many of whom remained in school only long enough to conceive a distaste for manual labor, but not long enough to acquire professional culture. It was believed that these experiments opened a door to an education which combined the intellectual and physical; that both mind and body might be disciplined by processes which broadened the man, fitting him to become a useful member of the community and also a producer of wealth. It was maintained that the powers of observation, judgment, and induction could be cultivated, not only in schools of philosophy and science, but in schools of trade and technology. Considering the fact that only about one-sixth of the pupils entering the ordinary high school complete the course, and that most of those passing through the grammar school do not enter the high school at all, it seemed that some course should be adopted which would retain the majority of young people under pedagogic care by a combination of purely intellectual studies with those having an economic aspect. The result of attempting two such diverse ends has naturally given rise to rival schools, in one of which the intellectual aim, in the other of which the economic purpose, prevails. But it is perhaps best that the new system should not stiffen into set lines too early, or be at the outset forever and invariably fixed. Different classes in society and different localities in our states may well vary the curriculum according to ascertained needs. In most of our larger cities manual training schools form an accepted part of the public secondary instruction, to which a course in the grade school and grammar school is pre-requisite. Those private institutions which are perhaps now best known are the schools connected with the Drexel institute, Philadelphia; the Washington university, St. Louis; the Armour institute, Chicago; and that under the care of the Massachusetts Institute of Technology, Boston. The curriculum most favored in these institutions embraces, in mathematics, algebra, trigonometry, astronomy, and mechanics. In science, botany, chemistry, and physics, with elementary lessons in biology and geology, are introduced. Composition and rhetoric are not neglected, and in some schools excellent instruction is given in Latin and in modern languages. As specially distinctive of these schools, however, marked attention is paid to drawing, clay modeling, tinting, joinery, wood carving, forging, and founding. In some schools sewing and cooking are also taught. The result so far has been to retain many youth in school who would otherwise have cut their courses short; and the work done in these schools promises to make itself felt in raising the standard of mechanical execution in all the states of the Union.

Manzoni (*mȧn-zō'nē*), **Alessandro**, a great Italian novelist and poet, of the romantic school, was born at Milan, March 7, 1785, of a noble family. He published his first poems in 1806; sacred lyrics and two tragedies, one highly praised by Goethe, followed; but the work which gave Manzoni European fame was his historical novel, *I Promessi Sposi* ("The Betrothed Lovers"), a Milanese story of the 17th century, a powerful work, and interesting from its sketches of Italian life and customs, and especially the account of the plague in Milan. His famous ode, *Il Cinque Maggio* ("The Five Great Ones") was inspired by the death of Napoleon. He died at Milan, May 22, 1873.

Map, a drawing on a plane of the surface of the earth. As the earth is a sphere, it cannot be exactly represented on a plane or level surface, and various methods have been adopted to do away with the difficulty. The arrangement of the lines of latitude and longitude in circles is the most common way, and answers the purpose fairly well. The lines of latitude are numbered north and south from the equator, and the longitude east or west of a given line, usually either Greenwich, England, or Washington, in the United States. This serves to indicate the position of a country. Maps are made on a certain scale; as, one inch of the map may represent one mile of the country. Different colors are used to mark different countries, and water, mountains, high plains, etc., are also often indicated in the same way. The art of making maps is ancient, the Egyptians having made some rude attempts, though the Greeks consider Anaximander (560 B. C.) as the pioneer map-maker. In the 15th century, the revival of Ptolemy's teachings made a change in the charts made; Mercator and others among Italians and Germans made valuable contributions in the 16th century, and Sebastian Cabot made his map of the

world in 1544. A topographical map represents the details of a country very minutely, as the mountains, hills, rivers, and plains. A hydrographical map is one representing the waters of the world, as oceans, seas, bays, etc., with their coasts.

Ma'ple, a species of the genus Acer, being mostly trees well known by their palmately lobed leaves and winged fruits. The genus contains about 100 species, and is distributed throughout the temperate regions of the northern hemisphere. They are among the most prized of trees for park and street planting, and nearly all of them become finely colored in autumn. Among the numerous well-known species are *A. saccharum*, which produces the maple sugar and is perhaps the best and most popular of the maples for shade; and *A. saccharinum*, the "silver maple," with numerous varieties, is a quick-growing tree. Other prized forms are the "red" or "scarlet maple" (*A. rubrum*), which is common for street and park planting; "black maple" (*A. nigrum*); "Norway maple" (*A. platanoides*), resembling the sugar maple somewhat and occurring in numerous garden forms; the "box elder" (*A. negundo*), which is much used in the west.

Maple Sugar is made from the sap of the sugar maple, which grows in the northern part of the United States and in Canada. The trees are tapped in the spring, when there are warm days and frosty nights, which help the flow. A hole is made in the trunk with an auger or ax, in which a spout is stuck, through which the sap flows into a trough. It is then carried to a receiver, and, after straining, to the boiler. It is boiled and refined in the same way as cane sugar. A single tree yields from two to six pounds in a season. Good vinegar is made from it, and maple syrup, much better than sugar molasses, which is much used on buckwheat cakes, etc. New England is the great maple sugar region, but it is also made in Indiana, Michigan, New York, Ohio, and Pennsylvania. The yearly output of the United States is about 35,000,000 pounds.

SUGAR MAPLE.

Maracaibo (*mă-ră-kī'bō*), **Gulf of,** a wide inlet of the Caribbean sea, joined by a strait with the lake of the same name. The lake forms the floor of a great valley, shut in by high mountains. Its waters are sweet and deep enough for the largest vessels, but the mouth makes it difficult to enter. The gulf and lake were discovered in 1499 by Ojeda, who found here houses built on piles, and so called the region Venezuela — "Little Venice."

Marat (*mă-rä'*), **Jean Paul,** one of the foremost men in the French Revolution, was born at Boudry, in Neuchâtel, Switzerland, May 24, 1744, the son of a physician. He studied medicine and practiced for a time at London, becoming noted as a student of optics and electricity, his work and writings attracting the attention of Franklin and Goethe. In 1788, he started his famous paper, *L'Ami du Peuple* (The Friend of the People). Throughout the Revolution he fought for his own hand, denouncing in turn Necker, Bailly, Lafayette, the king, Dumouriez, and the Girondins. His paper made him hated, but made him also the darling of the scum of Paris, and placed great power in his hands. His printing press had to be hidden from the eyes of Lafayette's police; twice he had to flee to London, and once was forced to hide in the sewers of Paris. There is no doubt that on his head rests in great measure the guilt of the September massacres. He was chosen a member of the convention, and was perhaps the most unpopular man in the house. When the republic was set up, Marat changed the name of his paper to the *Journal of the French Republic*. He was now dying of a disease caught in the sewers, and his last energies were spent in a death-struggle with the Girondins. Marat was accused by them before the tribunal, and his acquittal marked their own downfall. He was now so weak that he could only write sitting in his bath, where Charlotte Corday's knife put an end to him, July 13, 1793. The beautiful Charlotte, whose lover had been killed by a mob, and who said she had stabbed one man to save the lives of one hundred thousand, was guillotined, while Marat was buried with the greatest honors. See the *Histories of the French Revolution*, by Mignet, Thiers, Michelet, Louis Blanc, Carlyle, and Von Sybel.

JEAN PAUL MARAT.

Marathon (*măr'a-thon*), a village on the coast, 18 miles northeast of Athens, Greece. Here the Persian hordes of Darius were defeated, in 490 B. C., by the Greeks under Miltiades — one of the decisive battles of the world. The Persians numbered about 110,000. Against them came 10,000 heavy-armed

Athenian infantry and a small body of light-armed troops. A re-enforcement of 1,000 heavy-armed Platæans encouraged Miltiades to leave his position on the heights and attack the Persians who filled the plain below. The Greeks advanced in three bodies. The two wings carried everything before them, but the center was driven back. The wings now fell on the flanks of the Persian center and drove the whole army to their ships, which were drawn up on the beach. The Persian loss is put at 6,400; that of the Greeks at but 192. Had the Athenians been conquered, all Greece would have become a part of Persia.

Maratti (*mä-rät'tē*), **Carlo,** an Italian painter, was born near Ancona, Italy, in 1625. He studied at Rome and became a great admirer of Raphael's paintings. A picture of Constantine destroying the idols made him one of the first painters of his time. His masterpiece is the *Martyrdom of St. Biago*, at Genoa. He died at Rome, Dec. 15, 1713.

Mar'ble. In its popular sense, the term "marble" is applied to any crystalline rock composed principally of lime carbonate or of lime and magnesia carbonates, if it has a color which makes it desirable for decorative or monumental purposes, or for building stone, and a texture which renders it susceptible of polish. In origin, it is generally a metamorphosed limestone. It therefore occurs chiefly in regions of metamorphic rock. Between limestone which is not crystalline, and marble, there are all gradations, and thoroughly crystalline limestone, if it is not valuable for some of the purposes mentioned above, is rarely called marble. The color of marble depends on the purity of the limestone from which it is made. If considerable quantities of materials other than lime carbonate or magnesia carbonate are present, the color depends upon the nature and distribution of these impurities in the rock. Pure marble is white, but impurities may make it red, brown, yellow, black, or, if the impurities be irregularly distributed, the marble may be mottled or clouded. Onyx, or onyx marble, is a variety of marble formed by the precipitation of lime carbonate in solution, usually from the waters of springs. All limestone formed by precipitation is *travertine*, which includes stalactites, stalagmite, etc., but only those varieties of travertine which have beautiful colors, and are translucent, are called onyx. Onyx is used for decorative purposes in the interiors of buildings, for wainscoting, lavatories, etc. The onyx of ancient time was derived principally from Egypt. The principal American sources are Mexico, the peninsula of Lower California, southern California, and Arizona. The colors of onyx are various, white, yellow, and green being common. It is often mottled and beautifully veined. Certain varieties of variegated serpentinous rock are sometimes called verdantique marble. Marble is widely distributed, but the commercial product of the United States is derived mainly from the following states, named in the order of the value of their marble products in 1898: Vermont, Georgia, New York, Tennessee, Maryland, California, Pennsylvania, Massachusetts. The total value of the marble output of the United States in 1898 was over $3,500,000, and more than one-half of this came from Vermont.

Marc'anto'nio or **Raimon'di,** an Italian engraver, was born at Bologna late in the 15th century. He was a goldsmith by trade. He copied, on copper, wood engravings of Dürer, and at Rome, where he worked from 1510, he engraved many of Raphael's paintings, and is held to be the greatest of the engravers of the great painter. He died in 1534.

Marcel'lus, Marcus Claudius, a famous Roman general, came of a plebeian family. In his first consulship—222 B. C.—he defeated a part of the Gauls and slew their king with his own hand. In the second Punic war he took command after the defeat at Cannæ and checked the victorious Hannibal at Nola in 216. Two years later, as consul for the second time, he blockaded Syracuse, and helped by famine and pestilence, and by the treachery of the Spanish allies of the Syracusans, he entered the city in 212, and soon conquered all Sicily. In his fifth consulship—208 B. C.—he fell in a skirmish against Hannibal, near Venusia, Apulia.

March, the third month of the year and the first in the Roman calendar, has 31 days. It was held to be the first month in England till the change of style in 1752. Its last three days were once supposed to have been borrowed from April, and according to an old proverb are always stormy. March is named after the Roman god, Mars.

March, Francis Andrew, an American philologist and scholar, was born at Millbury, Mass., Oct. 25, 1825. He graduated at Amherst college in 1845, where he was tutor for two years. After studying law, and teaching for three years, he became instructor at Lafayette college, where he has since taught, from 1858 being professor of the English language and comparative philosophy. Professor March ranks as one of the first of American philologists. He has published *An Anglo-Saxon Grammar*, *A Method of Philological Study of the English Language*, etc.

Marchantia (*mär-kan'shĭ-a*), a genus of plants belonging to the liverworts, whose species have prostrate and thick thallus bodies, which put out rhizoids from the under surface, and are green on the upper surface. Small cups ("cupules") also are borne on the upper surface, which contain numerous disk-like gemmæ for vegetative propagation.

Each thallus body also sends up a conspicuous vertical branch, on the summit of which is a disk bearing the sex organs. The disk with scalloped edge bears the male organs (antheridia), while the star-shaped disks bear the female organs (archegonia). The most common species is *M. polymorpha*, abundant on damp ground and moist cliffs. See HEPATICÆ for figure.

Marchesi (*mär-kā'sē*), **Pompeo,** an Italian sculptor, was born in 1789. He was a pupil of Canova, became professor in the Academy of Fine Arts, and one of the foremost sculptors of modern Italy. His masterpiece is *The Good Mother*, the Virgin with the dead Christ in her lap, which is in the church of San Carlo at Milan. Other works are his statues of *Goethe* at Frankfort, *Venus Urania*, and *St. Ambrose*. He died at Milan, Feb. 7, 1858.

Marco'ni, William, a distinguished electric engineer, born at Marzabotto, Italy, in 1875, and educated at the University of Bologna, especially under the direction of Professor A. Righi, an eminent physicist and high authority on electrical vibrations.

Marconi's chief accomplishment is the perfection of a system of wireless telegraphy by use of Hertzian vibrations. His first successful experiments were performed in England in 1896. See MAXWELL, JAMES CLERK-.

Marco Polo. See Polo.

Mar'cy, William Learned, an American politician, was born at Southbridge, Mass., Dec. 12, 1786. He was brought up on a farm and graduated at Brown university in 1808. He became a lawyer, but when the War of 1812 broke out he entered the army as a lieutenant. He went with a detachment to capture some Canadian militia at St. Regis. Though not the commanding officer, Marcy led the attack, broke open the door of the blockhouse, and forced the militia to surrender. These were the first prisoners taken on land in the war. For some years he was editor of a Democratic paper at Troy, N. Y. In 1823, he was chosen comptroller of the state; in 1829, was appointed justice of the state supreme court; and two years later became United States senator. In 1832, he resigned to become governor of New York, was twice re-elected, but was defeated by Seward in 1838. He was secretary of war in Polk's administration, which covered the era of the Mexican war. He was also of great service in the settlement of the Oregon boundary question with England. As secretary of state under Pierce, he carried on the foreign affairs of the government in a masterly manner. Throughout his public life he showed great ability as a writer, statesman, and diplomatist. Marcy was the author of the famous political maxim, "To the victors belong the spoils." He died at Ballston Spa, N. Y., July 4, 1857.

Mardi Gras (*mär'dē-grä*), meaning "fat Tuesday," the day before Ash Wednesday, (the first day of Lent), the same day that was formerly celebrated in England as "Shrove Tuesday." The custom of holding high carnival and making merry on that day was observed for hundreds of years in Europe and is still kept up in some of the southern cities of the United States, especially at New Orleans. It was introduced there in 1827 by Creoles who had taken part in the festival at Paris. The day is a legal holiday, and all the afternoon the streets are filled with masqueraders, and balconies and windows with spectators. An ox, with its horns covered with wreaths, heads a procession of butchers. The carnival king "Rex" appears at noon, the papers having beforehand announced his landing at New York or some other port, and told of his courage in war. He is represented usually as a gray-bearded, dignified man. Two pages go before him carrying his scepter and the keys of his kingdom on velvet cushions. There is also a night parade of young gentlemen maskers dressed to represent some poem, as *Lalla Rookh*, or a feast, the Darwinian theory, etc. The day ends with a ball, where Rex chooses his queen.

Maren'go, a village near Alessandria, of northern Italy. Here, on June 14, 1800, Napoleon with 33,000 French defeated 30,500 Austrians under Melas. The absence of Napoleon when the fighting began came near giving the Austrians a victory. It was the cavalry charge of the younger Kellermann that decided the day, and gained upper Italy for France. The Austrian loss was 6,400, besides 3,000 prisoners; the French loss 7,000. General Desaix was among the killed.

Mar'garet, queen of Denmark, Norway, and Sweden, was the daughter of Waldemar IV. of Denmark, and wife of Hacon VIII. of Norway. She was born in 1353. By the death of her father she became regent of Denmark in the name of her son, who soon died, and then of her grandnephew Eric of Pomerania. The death of her husband made her ruler of Norway (1388), and the dissatisfied subjects of Albert, king of Sweden, asked her to take that country too. She sent an army into Sweden which defeated the king's troops and took Albert and his son prisoners. Sweden was wholly conquered, and in 1397 the famous union of Kalmar was agreed upon, whereby the three kingdoms were to stay forever at peace under one king, though each was to keep its own laws and customs. Margaret also got possession of Lapland and part of Finland. She was a woman of great energy and strong will, and ruled with a firm hand. She has been called the "Semiramis of the North." She died Oct. 28, 1412.

Margaret of Anjou (*mär'ga-rĕt of on-zhōō'*), queen of England, wife of Henry VI., and daughter of René of Anjou, titular king

of Sicily and Jerusalem, was born at Pont-à-Mousson, in Lorraine, March, 1429. At the age of fifteen she was married to King Henry VI. of England, then in his twenty-fourth year. The queen soon proved herself superior to her husband in force of character and in executive qualities; and when the English threatened the security of the throne, because as a condition of her marriage all the English possessions in France were surrendered to the French except the single town of Calais, she proved herself to be the real ruler of the kingdom and the commander of the English armies. She had been married but five years and was only twenty years old when the insurrection of Jack Cade occurred, when for a time the city of London was in the hands of the mob; and soon after began the Wars of the Roses, the title of her husband to the throne being disputed in arms by the Duke of York, who was descended from an elder brother than was Henry VI. But Margaret defeated the Duke, and he was slain in battle at Wakefield (1460); and by the second battle of St. Albans she released her husband, at that time a captive in the hands of his enemies. By the help of Warwick, "the kingmaker," she succeeded in seating her husband once more upon the throne; but Warwick being soon after killed at Barnet, Margaret fell into the hands of the Yorkists and was imprisoned in the Tower of Windsor until 1475 when she was ransomed by Louis XI. of France, who paid 50,000 crowns for her release. Margaret sought refuge in France and died at Dampierre, Aug. 25, 1482, but little over fifty years of age, having spent twenty years of her life in constant war and four years in prison.

Mar'garet of Navarre (*nä-vär'*), sister of Francis I. of France, was born at Angoulême, France, April 11, 1492. She was carefully taught and very early became popular because of her charm of manner and strength of mind. After the death of her first husband, the duke of Alençon, she married Henri of Navarre, and so became the grandmother of the great French king, Henry IV. She encouraged farming, arts, and learning, and courageously sheltered reformers like Marot and Bonaventure. Her writings include interesting letters, poems called *The Marguerites of the Marguerite*, and the noted *Heptameron*, stories modeled on the *Decameron* of Boccaccio, which most scholars believe to be the joint work of Margaret, Bonaventure, and other men. See her *Life*, by Miss Freer, also her *Letters*, which appeared in England in 1841–42. She died at Bigorre, France, Dec. 21, 1549.

Margaret, Saint, queen of Scotland, was born in Hungary in 1047. From her tenth year she was brought up at the court of Edward the Confessor, her great-uncle. In 1068 with her mother and sister and young brother, Edgar the Atheling, she fled to Scotland. Young, lovely, learned, and good, she won the heart of the Scottish king, Malcolm Canmore, who married her the next year (1069). She did much to civilize Scotland, and built a fine church at Dunfermline. She had the greatest desire to help the people among whom her lot was cast, was very religious, and unselfishly did whatever duty lay before her. She died at Edinburgh, Nov. 16, 1093, and one hundred and fifty-seven years later was made a saint by Pope Innocent IV. See Skene's *Celtic Scotland*.

Margate, an English seaport in the Isle of Thanet, at the eastern extremity of Kent, has for many years been (with Ramsgate) a famous seaside resort. Its bracing air, good bathing, and fine beach attract thousands of visitors. Its long pier, jetty, theatre, "zoo," old churches, and town hall are some of the features of the place. Here were landed the wounded brought back from the field of Waterloo, and here the painter Turner went to school. Population 18,900.

Maria Christina (*mä-rē'ä kris-tē'nä*), queen of Spain, was born at Naples, Italy, April 27, 1806. She was the daughter of Francis I., king of the two Sicilies, and became the fourth wife of Ferdinand VII. of Spain. On Ferdinand's death in 1833, she became regent in the name of her daughter, Isabella. During the civil war of the Carlists, which threatened her power, she was deaf to everything but her love for her second husband, the Chamberlain Munoz. In 1836, a conspiracy forced her to yield a constitution to the people. Another rising in 1840 forced her to give up the regency and go to France. Returning in 1843, she was exiled by the patriotic party in 1854, but was back again ten years later, and driven out finally in 1868. She cared little for the Spaniards, except to keep her own power in the country. Maria died at Havre, France, Aug. 22, 1878. See Furley's *In Spain amongst the Carlists*.

Maria Louisa (*mä-rē'lō-ē'za*), empress of the French, second wife of the Emperor Napoleon I., was the daughter of the Emperor Francis I. of Austria. She was born Dec. 12, 1791, and married to Napoleon, after the divorce of Josephine, April 2, 1810. She bore a son to the emperor March 20, 1811, who was called king of Rome. At the beginning of the campaign of 1813 she was appointed by the emperor regent during his absence, but with many restrictions upon her authority. On the overthrow of Napoleon, she went first to Orleans and then to Rambouillet. Later she made Schönbrunn her home, where she remained until 1816. She received by the peace of Paris, the duchies of Parma, Piacenza, and Guastalla. After the death of Napoleon, she married Count Neipperg. She died at Vienna, Dec. 17, 1847.

Maria Theresa (*ma-rē'ä te-rē'sä*), empress of Austria, was the daughter of Charles VI.,

and was born at Vienna, May 13, 1717. Her father got the powers of Europe to sign the pragmatic sanction which gave the right of succession to the throne to the females as well as to the males of the royal line. When she came to the throne, in 1740, she found the government without money, the people discontented, and the army weak; while Prussia, Bavaria, Saxony, and Sardinia put forward claims to all or parts of her dominions. Frederick the Great poured his armies into Silesia; Spain laid hands on Austrian Italy, and the Bavarians invaded Bohemia and threatened Vienna. The young queen was saved by the chivalrous faithfulness of the Hungarians, to whose loyalty she appealed with her baby son in her arms, and by her own courage and energy. The Seven Years' war of the Austrian succession ended with the peace of Aix-la-Chapelle, in 1748, by which Maria lost territory to Prussia, Spain, and Sardinia, but had her rights recognized, and also those of her husband, Francis, grand-duke of Tuscany, who was crowned emperor. In the years of peace that followed she fostered farming, manufactures, and trade, nearly doubled the national revenues, and at the same time lessened the taxes and strengthened her armies. But the loss of Silesia rankled deeply in her mind, and she began the Seven Years' war with Frederick the Great, which only served to strengthen his hold on the lost province. She then endeavored to strengthen the country in every way, bettered the condition of the peasants, ameliorated criminal punishments, and founded schools and charitable societies. By the first partition of Poland she got Galicia and Lodomeria, and obtained Bukowina from Turkey. Maria Theresa was majestic and winning, and had the undaunted spirit of a true queen. She won the love of her subjects and raised Austria from a wretched condition to power. She died at Vienna, Nov. 29, 1780. See *Maria Theresa and Frederick the Great*, by Duc de Broglie; and narratives of the Seven Years' war.

Mar'iazell', a famous place of pilgrimage in Austria, is in Styria, 60 miles southwest of Vienna. The image of the Virgin, which draws thousands of pilgrims yearly, is enshrined in a magnificent church, built in 1644 A.D.

Marie Antoinette (*mă-rē' ŏn-twă-net'*), **Josephe Jeanne,** the most ill-fated of the queens of France, was the fourth daughter of Maria Theresa of Austria and was born at Vienna, Nov. 2, 1755. She was married to Louis XVI. of France, then the dauphin, in 1770. A mere child in years, neglected by her young husband, and bored by the stiff etiquette of the old court of France, she spent money recklessly, went on night drives to Paris, appeared at masked balls, and became passionately fond of the card-table. When, in 1774, she became queen, her open favoring of Austrian interests, and her enmity to Turgot and Necker, and their measures for stopping the distress of the country, made her distrusted and disliked. The people came to think that the miseries of France were wholly caused by the extravagance of "the Austrian," as she was called. She was also attacked in pamphlets under the names of "Madame Deficit" and "Madame Veto." The joyous girl had now become a courageous and obstinate woman, who forced the king into a backward policy, to his undoing. As Mirabeau said, the only man the king had about him was his wife. Amid the horrors of the march of women to Versailles, she alone did not lose heart, and she showed herself on the balcony to the raging mob with a cool bravery that for a moment overawed the fiercest into respect. But she was a Royalist to the core, disliked liberal noblemen like Lafayette and Mirabeau, and utterly failed to understand the troublous times into which she was flung. The death of Mirabeau, in 1791, took away the last hope of saving the monarchy, and less than three months later took place the fatal flight to the frontier which was stopped at Varennes. Quickly followed the storming of the Tuileries, the transference to the Temple, the trial and execution of the king, and then Marie's son was torn from her arms, and she herself sent to the Conciergerie like a common criminal. After eight weeks more of insult and brutality, the "Widow Capet," as she was styled, was herself tried in her ragged dress and gray hair before the revolutionary tribunal. With calmness she went through the two days and nights of questioning, was sentenced, and on the same day at Paris on Oct. 16, 1793, perished under the ax of the guillotine, just twenty-three years after she had left Vienna, a beautiful girl. See the histories of the French revolution by Thiers, Mignet, Michelet, Louis Blanc, Carlyle, and Von Sybel; and Lord Ronald Gower's *Last Days of Marie Antoinette.*

Marietta, a city of Ohio, capital of Washington county, on the Ohio river, at the mouth of the Muskingum, 95 miles southeast of Columbus. Founded in 1788, largely by officers of the Revolutionary war, it is the oldest town in the state, and the first settlement in the Northwest Territory. Remarkable traces of the early moundbuilders are visible here. It is the seat of Marietta college, founded in 1835, and having 13 professors and instructors, 200 students, and a library of 45,000 volumes. Its manufactures include the largest chair factory in the state. The discovery and development of rich deposits of petroleum in the surrounding region has greatly stimulated the growth of the city in recent years. Population 13,348.

Marigold (*măr'i-gōld*), a name given to certain plants of the same order as the chrysanthemum and dandelion. Pot marigold is a native of France and southern Europe, with

an upright stem, one to two feet in height, with large, deep-yellow flowers. These flowers are sometimes used in flavoring soup and in coloring cheese. Some kinds are natives of America. Corn marigold is a chrysanthemum.

Marinette (*măr-i-nĕt'*), a town in Wisconsin, at the mouth of the Monominee river. It contains iron foundries, sawmills and planing mills, and its chief industry is lumbering. Population 16,195.

Mario (*mä-rē-ō*), **Giuseppe,** a famous Italian opera-singer, was born at Cagliari, Italy, in 1812, and was the son of General di Candia. After serving some years in the army, he went to Paris, where his voice and charming manners made him highly popular. His heavy debts forced him to sing for a living, and in 1838 he made his first appearance in opera as "Robert," in *Robert le Diable*, (Robert the Devil). In this he achieved the first of many successes in Paris, London, St. Petersburg, and America. He was generous and always ready to help struggling artists. Mario married the famous singer Giulia Grisi, and retired from the stage in 1867. He died Dec. 11, 1883. See Engel's *Musical Celebrities*.

Mar'ion, Francis, General, was born at Winyaw, S. C., in 1732. Marion came of a Huguenot family, had little schooling, and in 1759 served in a cavalry troop commanded by one of his six brothers in an expedition against the Cherokees. At the outbreak of the Revolutionary war, he was a member of the South Carolina congress. As captain of a company he served in a successful attack on Fort Johnson at Charleston. In 1777, with but 600 men, he vainly tried to defend Georgia from the British. In 1779, he was intrusted with the command of Fort Moultrie. During the siege of Charleston he accidentally broke his leg and was carried out of the city with the other wounded. As he grew better, he gathered his neighbors about him, and gradually built up the brigade that afterward became so famous. Colonel Marion's small and ragged regiment was rather looked down upon by General Gates, when it marched into camp. But when Gates was defeated at Camden, Marion, who had been sent to destroy the boats on the rivers, rescued the American prisoners.

Marion's brigade now began those marches, forages, and surprises, which crippled the enemy severely. His main camp was at Snow's island, hid among impassable swamps; but he also had hiding-places in almost every Carolina marsh. He cheerfully slept without a blanket and marched without a hat. It is said that a British officer, sent to ask an exchange of prisoners, was led blindfolded into the "Swamp Fox's" camp. General Marion politely invited him to dinner, and the officer was surprised to find that the meal was made up wholly of sweet potatoes roasted in the ashes and served up on a piece of bark, and a drink made of vinegar and water. The officer on going back to the army, threw up his commission, saying he could not fight against men whose patriotism went to such lengths. After the war, Marion was a member of the state senate and helped to frame a state constitution. He died near Eutaw, S. C., Feb. 28, 1795. See *Life*, by Horry and Weems; also *Life*, by Simms.

Mar'ion, Ind., a thriving city and important railroad center, the capital of Grant county, northeastern central Indiana, 66 miles northeast of Indianapolis. It is the seat of a national soldiers' home, a normal college, high schools, etc., and has many manufacturing establishments, including malleable-iron works, rolling and flour mills, glass factories, etc. In the past decade it has doubled its population, its present inhabitants numbering 17,337.

Marius (*mā'ri-us*), **Caius,** a famous Roman general, who was seven times consul, was born of an unknown family at Cereatæ, Italy, 157 B. C. He was under the younger Scipio at the siege of Numantia in 134 B. C. In 119 he was made tribune of the plebs, and became a popular leader by his vigor against the nobles. In 114, as proprætor of Spain, he cleared the country of the robbers from which it had greatly suffered. After marrying Julia, the aunt of the great Cæsar, he served in Africa during the war against Jugurtha. After a year as consul he went back to Africa, as proconsul of Numidia, and successfully finished the war against Jugurtha, in 106. But the honor of capturing the beaten king fell to Sulla, and was the beginning of his jealousy of his lieutenant, which later on caused the bloody civil war. In 104, and also in the next three years, he was chosen consul, as it was felt that Marius alone could save Rome from the hordes of Cimbri and Teutones which had burst into Gaul and slaughtered several bodies of Roman troops. The war lasted two years, but finally the Teutons were blotted out, in a two days' battle at what is now Aix, in Provence, in which from 100,000 to 200,000 were killed. When, besides this success, he had overthrown the Cimbri and Rudii, the Romans were wild with joy, called him the saviour of the state, and made him consul, for the sixth time, in 100 B. C. This was the height of his power. His jealousy of Sulla, who had been given charge of the war against Mithridates, brought on the civil war, in 88. Marius was soon forced to flee, and after hardships and hairbreadth escapes reached Africa. During his flight his hiding-place was discovered, and he was flung into prison at Minturnæ. Here, when a Cimbrian slave was sent to kill him, "Wretch, darest thou slay Caius Marius?" said the old hero as he glared on him out of the gloom of the dungeon. The slave fled in terror, saying, "I cannot kill Marius"; and the citizens, looking on it as an omen, allowed the exile to escape. When his friends rose

under Cinna, he hurried back to Italy, and the two generals marched on Rome, which was forced to yield. In revenge against the aristocracy, Marius let loose a band of 4,000 slaves, who kept up their work of murder for five days and nights. Marius and Cinna were chosen consuls in 86, but Marius had only held office seventeen days when he died. See Michelet's *Roman Republic;* Mommsen's *History of the Roman Republic;* Sewall's *Child's History of Rome;* Yonge's *Young Folks' History of Rome.*

Marjoram (*mär'jō-ram*), a class of plants of which several kinds are common, as pot and sweet herbs in gardens. The common marjoram is a native of Great Britain, and is sweet-smelling, with a bitter taste. The dry leaves are sometimes used instead of tea. The plant-tops are used as a purple dye for woolen cloth. Oil of marjoram is also distilled from the plant. Pot, knotted, and winter-sweet marjoram are other varieties.

Marjorie (*mär'jo-ry*) **Fleming,** a little Scotch girl, made immortal by the pen of the Scottish writer, Dr. John Brown, of Edinburgh. She was born at Edinburgh, Jan. 15, 1803. She was very bright and precocious, writing poetry, reading Swift, Pope, and Gray, and Newton *On the Prophecies*, and *Tom Jones*, and reciting Shakespeare by the hour. She was a great pet of Sir Walter Scott, who almost every day either visited her or carried her off, wrapped in his shepherd's plaid, to his "den," and amused himself for hours with the bright talk and learned quotations of his "Maida," as he called her. Scott says of her: "She's the most extraordinary creature I ever met with, and her repeating of Shakespeare overpowers me as nothing else does." She died Dec. 19, 1811, when only eight years old. The beautiful story of her short life is now an English classic, and can be found in the second series of *Spare Hours*, by Dr. John Brown.

Mark, called "John, whose surname was Mark," is held to be the author of the second Gospel. Of Mary, his mother, nothing is known except that her house in Jerusalem was visited by Peter and the other disciples. By some Mark is thought to be the young man mentioned in Mark XIV. 51 and 52. Mark went with Paul and Barnabas on their first missionary journey from Antioch in Syria as far as Perga in Pamphylia; here he quitted them, why, we know not; but his leaving led Paul to refuse to take him along on his second journey, and this refusal caused Barnabas to part company with Paul. Paul seems afterward to have been his friend, and refers to him as a useful fellow-worker. Of the remainder of his life we know nothing certain. He is thought to have been Peter's companion, either at Babylon or at Rome. In the art of the middle ages Mark is represented by a lion. The Gospel of Mark was written about 70 A. D., and is probably based on Peter's memory of his Master, and the scenes he had himself passed through. It is pretty certain that the evangel of Mark was the first Gospel to be written.

Mark An'tony. See ANTONY.

Mark'ham, Sir Clements R., an English naval officer, geographer and author, was born at Stillingfleet, Yorkshire, England, July 20, 1830. Sir Markham is the son of Rev. David F. Markham, vicar of Stillingfleet and canon of Windsor. He was educated at Westminster school, and entered the English navy in 1844, at the age of fourteen. He served in the Arctic expedition in search of Sir John Franklin when but twenty years old. He left the navy the next year, and spent two years in travel in Peru. As a result of these travels and studies, he introduced into India the cultivation of the cinchona tree, from which quinine is obtained. He acted as geographer of the Abyssinian expedition in 1867–8. He was created a knight in 1896, being president of the Royal Geographical society, the International congress, and of the Hakluyt society. He has published many works of great value, including *Franklin's Footsteps, Life of the Great Lord Fairfax, The Fighting Veres, History of Peru, Threshold of the Unknown Region, Memoirs of the Indian Surveys, History of Persia, History of the Abyssinian Expedition, Missions to Thibet, Lives of Columbus, John. Davis and Major Rennell, Ollanta* (a Peruvian drama, translated from the Quichua), *The Paladins of Edward the Great, Travels in Peru and India, Cuzco and Lima*, a *Quichua Grammar and Dictionary, Peruvian Bark, The War between Peru and Chile*, and he has edited many volumes of the *Hakluyt Society Transactions.* Even the long list here given contains but part of his distinguished contributions to travel, science, biography, and geographical information.

Mark Twain. See CLEMENS.

Marl, a natural mixture of clay and carbonate of lime. The proportion of lime varies from 6 to 20 per cent. Marly soils are usually very rich, and marl has been used as a fertilizer from very early times. An English law of 1225 gave every man the right to sink a marl pit on his own ground.

Marlboro (*märl'bŭr-o*), **Mass.,** a city in western Middlesex county, 15 miles east of Worcester, and 25 miles west of Boston. It is on the lines of the Fitchburg and the New York, and New Haven and Hartford railroads, and lies in a good fruit-growing region. It is largely engaged in the manufacture of boots and shoes. It has some excellent public buildings, including city hall, soldiers' monument, public library, banks, schools, and churches. Population 13,609.

Marlborough (*mawl'b'ro*), **John Churchill,** Duke of, the ablest general of his time, was

born June 24, 1650, at Ashe, in Devonshire, England. His father had been made poor by his friendship for Charles I., and young Churchill had little schooling. As captain of a company of grenadiers he was sent to help Turenne to capture the fortresses on the Dutch frontier. Here his brilliant courage and ability gained him a colonelcy. His rise was further aided by his marriage with Sarah Jennings, a woman as remarkable for her talents and strong will as for her beauty. On the accession of James II., Churchill was made a baron and general, and took a leading part in putting down the rebellion of Monmouth. On the landing of the Prince of Orange, he stole away to the side of the invader, and was rewarded for his treachery by being made Earl of Marlborough. He was of great service to William III. in conquering Ireland, and as commander against the French in the Netherlands; but was not wholly trusted by the king, and on an untrue suspicion of being concerned in a plot, was imprisoned in the Tower, and was not given any public office for five years. When Queen Anne came to the throne, in 1702, he was given command of the British army in the Netherlands, and during the war of the Spanish Succession he showed his unrivaled generalship in carrying on some of the greatest campaigns of English history. Anne showered honors and offices on both Marlborough and his wife. Marlborough, in fact, became regent in all but name. In 1702, as commander of the Dutch and English forces, he drove the French out of Spanish Guelders. In 1704, together with Prince Eugene of Savoy, he routed the French and Bavarians at Donauwörth, and on August 13th won the great victory of Blenheim. Of 56,000 men the French and Bavarians lost 40,000, and the loss of the allies was fully 12,000. This battle stamped Marlborough as the first general in Europe, and the queen and the emperor vied in honoring the conqueror. In 1706, the duke renewed that career of victory which broke the spell surrounding the great power of France under Louis XIV., who gloried in calling himself the "Invincible." On May 23, 1706, the battle of Ramilies was fought, which obliged the French to leave the whole of Spanish Flanders. But, in 1708, their attempt to recover this lost ground led to the battle of Oudenarde, fought July 11th, which resulted in an utter defeat of the French. The surrender of Lille and Ghent ended the campaign. In 1709, was fought the battle of Malplaquet, as Marlborough himself said, "a very murdering battle." The numbers were about even, but the French had the best position. The slaughter was tremendous, the casualities reaching 20,000 on the side of the allies and 8,000 on that of the French. The last campaign was in 1711, and when town after town had been taken from the French, the treaty of Utrecht gave thirty years' peace to Europe. Meanwhile the queen, tired of the tyranny of the duchess of Marlborough, who had ruled her as a child, threw off the yoke. The charge of having embezzled public money was brought against the duke, and he was stripped of all his offices till George I. came to the throne in 1714, when, in a day, he was again placed where he had stood after the battle of Blenheim. He died near Windsor, June 16, 1722. See Coxe's *Memoirs*, Saintsbury's *Life*, and Thackeray's *Henry Esmond*.

Marlitt (*mar-lēt'*), **E.** (*nom de plume* of "Eugenie John"), novelist; born at Arnstadt, Germany, Dec. 25, 1825. She began life as a public singer, but losing her voice soon after, for some years she lived as companion to the Princess of Schwarzburg-Sonderhausen, who had in earlier life assisted her. She began in 1863 the publication of those serial novels which made her famous, writing for *Die Gartenlaube*, an illustrated journal. Her best-known works are *Gold Else; Das Geheimniss der Alten Mamsell* (translated and published in English as *The Old Ma'mselle's Secret*) *Reichs-grāfin, Gisela* (Countess Gisela); *Die Zweite Frau* (The Second Wife); *Im Hause des Kommerzienrats; Im Schillingshof; Amtmanns Magd*, and *Die Frau mit den Karfunkelsteinen*. Her style was clever, popular, and eminently successful in winning a large number of readers, although her works were severely criticised by those usually accepted as authorities in literature. She died June 22, 1887.

Marlowe (*mär'-lo*), **Christopher,** the greatest English dramatist before Shakespeare, was a shoemaker's son, and was baptized at Canterbury, Feb. 26, 1563 or 1564. He studied at King's school, Canterbury, and at Cambridge. The earliest of his plays that we still have is *Tamburlaine the Great*, which was probably played in 1590. In spite of its bombast it is far ahead of any tragedy that had yet appeared on the English stage. It is in blank verse, of which Marlowe was the first to discover the strength and variety. Soon after was played *The Tragical History of Doctor Faustus*. Other playwrights have made additions to it, but parts of it show Marlowe's genius at its height, especially in the description of Helen's beauty. *Edward II.*, authorized to be played about 1593, is the ripest of his plays. It has not the fine poetry of *Faustus* and the first two acts of *The Jew of Malta*, but is better planned and more complete. *Edward II.* is fully equal to Shakespeare's *Richard III.* Charles Lamb says of it: "The death scene of Marlowe's king moves pity and terror beyond any scene, ancient or modern, with which I am acquainted." There is no doubt that Marlowe had a hand in the three parts of *Henry VI.*, and probably also in *Titus Andronicus*. His beautiful poem, *Hero and Leander*, was left unfinished. Shakespeare quoted in *As You Like It* the line, "Who ever loved that loved not at first sight?" and the watermen, too, sang

couplets from it as they sculled along the Thames. At Deptford, on June 1, 1593, at the age of twenty-nine, Marlowe met a violent death in a quarrel with a serving-man.

Marmont (*mär'mŏn'*), **Auguste Frederic Louis Viesse De,** was born at Châtillon-sur-Seine, France, July 20, 1774. He entered the army when quite young and met Napoleon at Toulon. His courage at the battles of Lodi, Castiglione, and San Giorgio earned him the rank of general of brigade in the campaign in Egypt. He commanded Napoleon's artillery at Marengo, after which he became general of division. In 1805, he defeated the Russians at Castelnuova and was made duke of Ragusa. In 1809, he won the battle of Znaim and was made a marshal. In 1811, he was given the chief command in Portugal, but a wound received in the battle of Salamanca (in which Wellington defeated him) sent him back to France. In 1813, he commanded a corps at Lützen, Bautzen, and Dresden, but in the beginning of 1814 was forced to make a truce with Barclay de Tolly, which obliged Napoleon to give up his throne. For this the Bonapartists called him a traitor. He took no further part in affairs till the Revolution of 1830, when at the head of a body of troops he tried to capture Paris, and with the few battalions that remained faithful to the royalist cause, he carried Charles X. across the frontier. He died at Venice, March 2, 1852, the last of the marshals of the first empire. His *Mémoires* have been published (1856–57).

Marmora (*mär'mo-ra*), **Sea of,** called the Propontis in early times, separates European from Asiatic Turkey and joins the Ægean sea by the Dardanelles (formerly the Hellespont) with the Black sea by the Bosphorus strait. It is in the form of an oval, 175 miles long and 50 miles broad. It covers 4,499 square miles and its greatest depth is 4,250 feet. The gulf of Ismid reaches about 30 miles eastward into Asia. There are several islands; the largest, Marmora, is famous for its quarries of marble and alabaster.

Marmoset (*mar'mō-zĕt'*), a small monkey of squirrel-like appearance inhabiting South America. The headquarters of the family is Brazil. They are the smallest of the monkey tribe, and the lowest of the Anthropoidea, the group which contains monkeys, baboons, and higher apes. They have a furry coat and a bushy tail, which is not prehensile. See MONKEY.

Mar'mot (*mär'mŏt*), a burrowing animal belonging to the group of ground squirrels. The common marmot is an European form inhabiting the Alps, Pyrenees, and other more northern mountains. The ground hogs, or woodchucks, so generally distributed in the United States and Canada, belong to the group. They are the largest and the heaviest animals of the squirrel family. They are about two feet long and covered with long coarse hair. Their ears are small, and their tails short and bushy. When numerous, wood-

ALPINE MARMOT.

chucks are a great pest, they eat nearly everything green, and are difficult to eradicate. There are three species in North America — the ground hog proper, the yellow-bellied marmot of the Rocky mountains, and the large hoary marmot further north. The prairie dogs are also marmots. See PRAIRIE DOG.

Marnix (*mär-nēks'*), **Philipp Van,** Lord of St. Aldegonde, a Dutch writer and patriot, was born at Brussels in 1538. He took an active part in the Reformation and in the rebellion of the Netherlands against Spain. A friend of William of Orange, he was appointed his representative at the first meeting of the estates of the United Provinces held at Dort in 1572. He went on special missions to the courts of England and France, and helped to bring about the union of Utrecht. In 1583, he was made burgomaster of Antwerp and defended the city for thirteen months against the Spaniards. Then he was forced to surrender, which act earned him so much ill-will that he left public life. He spent the remainder of his life in writing poems and satires. His song *Wilhelmus* (William of Nassau) is the famous hymn of Dutch liberty. Marnix died at Leyden, Dec. 15, 1598.

Maronites (*măr'ō-nīts*), one of the Christian sects of Syria, which takes its name from a monk called Maro, who lived in the 5th century, or perhaps from their first patriarch Maro. They were united with the Roman church in 1445, and in 1534 Gregory XIII. founded a college at Rome for the education of their clergy. They retain, however, their national rites and use the Syriac language in their liturgy. They number about 200,000, and are a sturdy, warlike race of mountaineers.

Maroons (*ma-rōnz'*), the name formerly applied in Jamaica and Guiana to escaped negro slaves. When the British won Jamaica from the Spaniards, in 1655, many slaves fled to the mountains. They and their descendants kept up a protracted warfare with the colonists for 140 years; but in 1795 they were conquered and part of them taken to

Nova Scotia, and afterward to Sierra Leone. The Maroons of Guiana, who are generally called bush negroes, about 4,000 altogether, form a number of independent bodies. See Dallas' *History of the Maroons*.

Marot (*mă-rō'*) **Clement,** a French poet of the time of Francis I., was born at Cahors, probably in 1496. His father was a poet and courtier, and Clement began to write verses when quite young, addressing many of them to Margaret, queen of Navarre, into whose service he had entered. He was wounded at the battle of Pavia, and imprisoned some months as a heretic. The reckless wit and satire of his poems made him enemies, and he was forced to flee from Paris. In 1538, he was back again, bringing out his translation of the Psalms, which became very popular. The Sorbonne condemned it and he fled to Geneva, and died at Turin in 1544. His gift lay in badinage and graceful satire. His poems were elegies, epistles, rondeaus, ballads, songs, sonnets, etc. His style had a good deal of influence on French writing.

Marquesas (*mär-kā'sȧs*) **Islands** are a group in Polynesia (the South Pacific) belonging to France. This group includes four or five islands discovered by Mendana in 1595, and also the Washington group of seven islands discovered by Ingraham in 1797. The Marquesas cover four hundred and eighty square miles, and are volcanic. In the time of Captain Cook, the natives numbered 100,000; by 1838 there were but 20,000, and now are only some 5,000. They are perhaps the finest race of brown Polynesians, courteous, but cruel and revengeful. The chief products of the islands are oranges and copra.

Marquette (*mär-kĕt'*), **Jacques,** a French explorer and missionary in America, was born at Laon, France, in 1637. When seventeen he became a Jesuit, and in 1666 was sent to Canada. He studied some of the Indian languages in the neighborhood of three rivers, and founded the mission at Sault Ste. Marie. He next preached among the Hurons and Ottawas, and when they were scattered by the Sioux, followed them to Mackinaw, where he built a chapel. He had heard of the Mississippi river from the Indians, and in 1673 was sent to explore it by Frontenac, the governor of Canada, together with Louis Joliet. With five other Frenchmen they left Mackinaw in two canoes May 17, and reached the Mississippi June 17, by way of Green bay, Fox river, and over a short portage to the Wisconsin. Near the mouth of the Ohio, they found Europeans, and were told by the Indians that it was not more than ten days' journey to the sea. They then went as far as an Indian village, probably near the mouth of the Arkansas, and now felt sure that they were not more than two or three days' journey from the mouth. They were also certain that the river emptied into the gulf of Mexico, and not, as had been thought, in Virginia or California, and not wishing to be captured by the Spaniards, they pointed their canoes upstream. They reached Mackinaw by way of the Illinois in September, having covered a distance of 2,500 miles. On the way back, Père Marquette had promised the Kaskaskia Indians to come and preach to them, and after a year's sickness, he set out for the country of the Kaskaskians, in October, 1764. Sickness forced him, however, to winter on the Chicago, and he did not reach the Indian village till the spring of 1765. He had hardly begun his mission when he became certain he could not live much longer, and set out to go back. He only got as far as the little river flowing into Lake Michigan, which bears his name, where he died. The story of his voyage and missionary journeys is told in Shea's *Discovery and Exploration of the Mississippi Valley*.

Marquette, a town in Marquette county, Michigan, situate 420 miles north of Chicago, on the southern shore of Lake Superior. Iron ore is mined in the region and shipped in great quantities, besides being used in its furnaces and foundries. It has also sawmills, machine shops, and a slate quarry. It is the seat of a Catholic bishopric. Population 10,058.

Marryat (*măr'i-ăt*), **Frederick,** English novelist and captain in the navy, was born in Westminster, England, July 10, 1792. In 1806, he went to sea as midshipman under the famous Captain (Lord) Cochrane. He saw some active and dangerous service off the coast of France and Spain and in the Mediterranean. His frigate was the *Impérieuse*, and he writes of her cruises in his private log that they "were times of excitement from the hour in which she hove up her anchor till she dropped it again in port; the day that passed without a shot being fired in anger was with us a blank day." He rose to be a commander when but twenty-three years old. He did good work in putting down the channel smugglers in the *Rosario*, and was sent out in command of the *Lorne* to Burma, where his men suffered badly in river and stockade fighting. He gave up the command of the twenty-eight-gun frigate, *Ariadne* in 1830, and the remainder of his life was spent as a writer. In 1837, Marryat made a tour of the United States, where he stayed two years. As a writer of sea-stories he has no superior, and, aside from Dickens, no English novelist has awakened heartier and more honest laughter. His books became immensely popular as soon as they appeared, and will always be the delight of boyhood. *Mr. Midshipman Easy*, *Jacob Faithful*, *Frank Mildmay*, *Peter Simple*, and *The Phantom Ship* are perhaps the best. Marryat died from overwork at Langham, Norfolk, Aug 9, 1848. See *Life and Letters of Captain Marryat*, by his daughter, Florence Marryat.

Mars, the early Italian god of war, and of farming. As the father of Romulus he was held to be the founder of the Roman race, and shared with Jupiter the honor of being called *Pater*. His priests danced in full armor. The wolf and the woodpecker were sacred to him. He had many temples in Rome, the most celebrated of which was the one on the Appian road, and the one to Mars the Avenger, built by Augustus in the Forum. The Campus Martius, where the Romans practiced athletic and military exercises, was named in his honor; so was the month of March. The games of Mars were celebrated every year in the circus on August 1.

Mars. See PLANETS.

Marseillaise (*mär-sē-yāz'*) **La,** the stirring song or hymn of the French republicans, was written in 1792 by Rouget de Lisle, a young officer then stationed at Strasburg. He composed both words and music one night in April, after dining with the mayor of the city. He called it a "Song of the Army of the Rhine." It was quickly carried by the revolutionists to the chief cities of France. It was brought to Paris by the volunteers of Marseilles, who sang it as they entered the city and when they marched on the Tuileries. So the Parisians called it *La Marseillaise*. Forbidden to be sung during the restoration and the second empire, it again became the national hymn on the outbreak of the Franco-Prussian war.

Marseilles (*mär-sālz'*), the third largest city of France, is situated on the Mediterranean, about 27 miles east of the mouth of the Rhône. It is the chief trade-port of France, the value of its imports and exports annually exceeding 2,250,000 francs. About 30,000 emigrants, most of whom are not French, embark at Marseilles yearly. Its harbor covers 70 acres, running into the heart of the city, and for a mile along the shore to the west are docks and warehouses. The chief industry is the making of soap, vegetable oils, and oil-cake. Soda, sugar, macaroni, iron, lead, zinc, tiles, and leather are also manufactured. There are large flour mills, wine vaults, and a good deal of fishing is done. The city is mainly built on the slopes overlooking the harbor. Its chief buildings are the cathedral, two interesting early churches, the health-office of the port, the museum, the Longchamp palace, and the public library. There is also a botanical and zoological garden, an observatory, and many special schools. Marseilles was the birthplace of Thiers. It is one of the oldest towns of France and was founded by Phoceans (Greek colonists) from Asia Minor about 600 B. C. For 900 years it was a center of Greek civilization. It sided with the Romans against its rival Carthage, and with Pompey against Cæsar, who stormed it in 49 B. C. It was held in turn by the Saracens, Charles of Anjou, Alphonso V. of Aragon, and came into the hands of Henry III. of France in 1575. In 1112, it was a republic. Louis XIV., in 1660, took away its privileges as a free-port, which it had had for centuries. In 1720 and 1721, nearly half the population of 100,000 died of the plague. Marseilles took a leading part in the French revolution, set up a commune in 1871, and was always noted for its republicanism. Its trade has grown fast since the French conquest of Algiers and the opening of the Suez canal. Population 442,239.

Marsh, George Perkins, an American philologist and diplomat, was born at Woodstock, Vermont, March 15, 1801, and died at Vallombrosa, Italy, July 24, 1882. He graduated at Dartmouth college in 1820, studied law, and was chosen to the supreme executive council of Vermont in 1835. From 1842 to 1849 he was a member of congress. While American minister to Constantinople from 1849–53, he was sent on a special mission to Greece. In 1861, he was appointed the first minister from the United States to Italy. While abroad he traveled in the east and in Europe, passing some time in Denmark, Norway, and Sweden, where he was recognized as a leading Scandinavian scholar. His lectures on English philology at Columbia college and Lowell institute in Boston, put him in the front rank of philologists. Among his books are *Lectures on the English Language*, *The Origin and History of the English Language*, *Man and Nature*, and *The Earth as Modified by Human Action*. See *Life and Letters*, by Mrs. Marsh.

Mar'shall, John, chief-justice of the United States, was born in Fauquier county, Va., Sept. 24, 1755. His law studies were interrupted by the Revolution, and he served in the army under his father, Colonel Marshall, from 1775 to 1779. In 1781, he began to practice law, and soon rose to the head of the Virginia bar. He was a member of the Virginia house of burgesses, the state legislature, and the state convention that adopted the constitution. He was sent to France with Pinckney and Gerry as envoys in 1797, and with Pinckney was ordered to leave the country when they had declined Tallyrand's request for a loan. In 1799, he was elected to congress, and in 1800 became secretary of state. He was made chief-justice of the United States in 1801, holding his position till his death, which occurred at Philadelphia, Pa., July 6, 1835. His decisions are considered authoritative on all matters of constitutional law. He wrote a *Life of Washington*. See *Life*, by Magruder, in "American Statesmen" series.

Mar'shalltown, a town in Marshall county, Ia., near the Iowa river, fifty miles northeast of Des Moines, with a large trade in grain. It has also foundries, machine shops, and manufactories of soap, flour, oil, and wire fencing. Population 11,544.

Marsh'mallow, a class of plants with showy flowers, natives of Europe and Asia. The common marshmallow grows in meadows and marshes. The whole plant is wholesome, abounding in fiber, mucilage, starch, and sugary matter, though the mucilage is chiefly in the roots. Marshmallow lozenges are very popular.

Mars'ton Moor, an historic plain, seven miles west of York, England, was the scene of a great victory of the parliamentary forces over the royalist army of King Charles I., in the English civil war, July 2, 1644. Twenty-two thousand royalists were led by Prince Rupert. The parliamentary troops were in three bodies, a Scotch army, a Yorkshire army under Fairfax, and one from the eastern counties under the Earl of Manchester, Cromwell, and Crawford, in all 15,000 foot and 9,000 horse. The battle was won in the short time between seven o'clock in the evening and nightfall, and the victory was mainly due to Cromwell's *Ironsides* scattering the troopers of Prince Rupert, who had hitherto carried everything before them. The royalists fled, leaving 4,000 men dead on the field. This victory gave the whole north to the parliament, and first brought Cromwell into notice. See S. R. Gardiner's *History of the Civil War*.

Mars'ton, Philip Bourke, one of the best-known of the younger late-day English poets, was born at London in 1850. John Marston, the poet and playwright of the reign of Queen Elizabeth, was an ancestor; while his father, Westland Marston, wrote among other dramas the highly successful play *The Patrician's Daughter*. Philip was a pretty child, and it was to him that his godmother, the author of *John Halifax*, addressed her well-known poem beginning: —

Look at me with thy large brown eyes,
Philip, my king.

Yet those handsome eyes went out into utter darkness, the result of a blow on one of them, got in a baby romp when Philip was but three years old. The blind boy began to write when he had hardly left off his nursery bibs. At his father's house he met and knew well Browning, Swinburne, Dickens, Miss Muloch, Rossetti, and many others. When of age his first book was published, *Song Tide*, sung in praise of his sweetheart. Three years later, appeared his second book, *All in All*, telling of his great grief for the death of this same betrothed. His last volume, *Wind Voices*, is considered his best. Marston's poetry has pleased readers and critics alike, and much of it will live and be remembered. Marston died Feb. 13, 1887.

Marsupials (*mär-sū'pi-als*), an order of the class Mammalia, embracing animals with a pouch or marsupium for containing the young. The pouch is a fold of skin on the ventral surface of the body. The young are born in a very rudimentary condition, and are attached to the nipples of the breasts shielded by the pouch. They are now of limited geographical range, but formerly, as shown by fossils, were in nearly all parts of the globe. All except the opossum belong to the Australian region. The opossum lives in South America and the southern part of the United States. Besides the opossums, the principal kinds of marsupials are: kangaroos, wombats, native bears, bandicoots, Tasmanian devils, and pouched dogs.

Mar'ten (*mär' tĕn*), the common name for a number of closely related animals widely known on account of their fur. They all belong to the genus *Mustela*. Besides the fur bearing the name of marten, all sables come from these animals. They are abundant in the northern portion of both the Old and New Worlds. They have long slender bodies, and short legs, and live mostly on trees. Their outer fur is long and glossy, and they have abundant soft under fur. There are two species in North America with a variety of local names. The black marten, black fox, fisher or Pekan, as it is variously called, is the largest of the group, being from two or three feet long with a tail one foot. It has no immediate relatives in the Old World. It feeds on mice, frogs, porcupines and steals frozen fish. The pine marten or American sable is about the size of a large house cat. It lives in dry spots of pine forests and also on other trees. It is similar to the pine marten of Europe. The stone marten is another common variety, with hair more inclined to grayish, and pure white on the breast. The Asiatic sable furnishes the celebrated sable, most costly of furs. "A single skin of a Russian crown sable with its natural dark bloomy black, will fetch $200. Of such, a muff and boa would be worth $2,000, but sets of inferior quality may be bought for $250." The best skins come from Yakutsk, Kamtschatka and Russian Lapland. The skins are in their best condition from November to January.

PINE MARTEN.

Mar'tha's Vine'yard, the name of an island lying off the southeast coast of Massachusetts. It is 21 miles long and 6 miles wide and forms Dukes county, Mass. It was discovered by Gosnold in 1602, and named by him; it was settled in 1642 by an English merchant, and from 1664 to 1692 belonged to New York. It has a lighthouse on the promontory of Gayhead, and is popular as a summer resort. The chief towns on the Island are Edgartown, Cottage City, Vineyard Haven, and Tisbury

Town. The island is separated from Nantucket island by the Muskeget channel.

Mar'tial, Marcus Valerius Martialis, one of the finest among the few Latin poets who did not borrow from the Greeks, and the greatest of all epigrammatists in verse, was born at Bilbilis, Spain, March 1, 38 or 41 A. D. After studying at home he went to Rome, where Piso, Seneca, and other leading men became his patrons. When Titus dedicated the Colosseum to the amusement of Rome, Martial wrote epigrams on the occasion which gained him the equestrian rank. He flattered the emperor Domitian, became popular as a diner-out, divided his day between the baths, theatres, and writing epigrams, had the leading senators as his friends, and all Romans who read anything at all as his readers. But he was always in want of money, could only get a new toga or mantle by asking some patron for it, and sometimes to escape duns was forced to retire to a country place probably given him by Seneca, and which he called his "foot of earth." After thirty-four years of Rome, the younger Pliny lent him money enough to go back to Spain, for which he was homesick. Here at Bilbilis a new patron gave him an estate on which, with its grove, its fountain, its vineyard, its garden, its fishpond, and its dovecote, he spent the rest of his life comfortably. Writing with the greatest ease and quickness, his epigrams show also a fine finish. As an epigrammatist he remains without an equal. He lifts the veil from the Rome of the time of Domitian and shows it mainly on its seamy side, with a likeness to life not outdone by the engravings of Hogarth. Martial died in Spain, in 104 A. D.

Mar'tin, the common name for certain large swallows found in Europe and America. The North American form is often called the purple Martin, on account of the color of its upper parts. Like other swallows, it has long wings and a deeply forked tail. It nests near houses, and where boxes are placed for it will occupy the same shelter year after year. The number of injurious insects destroyed by these birds is enormous — in the height of their activity, probably several hundred every day for each bird. The European house Martin is similar in habits.

Mar'tin, John, an English painter, was born at Haydon Bridge, Northumberland, July 19, 1789. He went to London in 1806, and after a hard struggle for a living became known by means of his picture, *Sadak in Search of the Waters of Oblivion.* His works were quite popular and were highly praised by Bulwer-Lytton. Among them are the *Fall of Nineveh. Belshazzar's Feast, The Last Man,* and *The Eve of the Deluge.* Martin died in the Isle of Man, Feb. 17, 1854.

Martin, Saint, bishop of Tours, was born at Sabaria, in the Roman province of Pannonia, about 316 A. D. His father, who was a military tribune, wished him to enter the army, which he did, serving first under Constantine and then under Julian the Apostate. Many stories are told of his upright life while a soldier — a remarkable thing in those days. Deciding to give his life to the church, he left the army, converted his mother to Christianity, and suffered much persecution from the Arian party in the church. About 360, he founded a monastery near Poitiers, but eleven years later was dragged by force from this retreat and made bishop of Tours. The fame of his saintliness and his reputation as a worker of miracles drew crowds of pilgrims from all parts of Gaul. Martin was the first in the Roman church who was given the title of "confessor" rather than martyr. He died between 397 and 401. His birthday is celebrated on November 11, and in Scotland this day still marks the beginning of winter and is called "Martinmas." St. Martin's day used to be begun with feasting and drinking, and so St. Martin came to be the patron of drinking and reformed drunkards. See Cazenove's *St. Hilary and St Martin.*

Martineau (*mär'-tĭ-nō*), **Harriet,** was born at Norwich, England, June 12, 1802. Her father was a manufacturer and gave her a good education. Before she was twenty, she began to write for the magazines, and in 1829 the failure of the firm in which she and her mother and sisters had placed their money obliged her to earn her own living. A series of stories, *Illustrations of Political Economy,* which she brought out in 1832, in spite of many discouragements and refusals from publishers, at once made her widely known. Five thousand copies of the first number were sold in two weeks, and from that day the way was open to her for life, and she never again had any want of employment or of money. In 1834, she came to America for two years and soon after published *Society in America.* As a girl she had been often unhappy and anxious because of ill-health, and now, from 1839 to 1844, she was again an invalid. Among her books are four volumes of children's tales: *Forest and Game-Law Tales; Letters on the Laws of Man's Social Nature and Development; Deerbrook,* a novel; *Biographical Sketches,* etc. One of her most important works was the careful translation of Comté's *Positive Philosophy.* Miss Martineau was a vigorous thinker, seeing clearly and saying clearly what she had to say. Her sympathy and kindness of heart won esteem for her, even of those who did not share her opinions, and few women writers have in their time enjoyed more fame than she did. She died in Westmoreland, June 27, 1876. See her *Autobiography.*

Martineau (*mär'tĭ-nō*), **James,** an Englishman, a Unitarian minister, and an author of note, was born at Norwich, England, April 21, 1825. His sister, Harriet Martineau, was

equally well known by reason of her own contributions to the press which were of a somewhat more radical character than those of the brother. Martineau was of a Huguenot family, settled in England, his father being a prosperous business man in the place of his birth. He was educated at private schools, the universities of England not being open at that time to dissenters. He was ordained by the synod of Munster, Ireland, in 1828, and began his work as assistant pastor of the Eustace Street Presbyterian church, Dublin, shortly after. The Irish Presbyterian church of that day, however, differed in doctrinal teaching from other denominations by the same name. Dr. Martineau gradually moved farther and farther from the standards of the synod, but claimed to the last to be a Presbyterian minister. He was soon appointed professor of philosophy in Manchester New college, and later principal of the same, serving in this institution from 1840 to 1886. He followed the college when it was moved to London in 1857. He received the degree of LL. D. from Harvard in 1872; that of D. T. from Leyden in 1875; that of D.D. from Edinburgh, in 1884; D. C. L. from Oxford in 1888; and D. C. L. from Dublin in 1892. He was a voluminous writer, chiefly upon philosophical and religious themes, his best-known works being *The Rationale of Religious Inquiry; Endeavors after the Christian Life; Types of Ethical Theory, A Study of Religion*, and *The Relations between Ethics and Religion*. Besides his separate volumes, he published in 1890–91 four volumes of essays and reviews collected from various periodicals. He died at London, Jan. 11, 1900.

Martinique (*mär-tĭ-nēk'*) is one of the Lesser Antilles in the West Indies. It is 43 miles long, from 12 to 20 broad, and covers 380 square miles. The island was discovered by the Spaniards in 1493, was settled by the French in 1635, and except for three short intervals, when it was held by the British, it has since 1635 been a French colony. A high, thickly-wooded ridge runs from north to south. The coast is high and indented, except on the west, where is the main trading town, St. Pierre (population 26,000), and the capital, Fort-de-France (population 17,275), which was nearly ruined by fire in 1890. Half the land tilled is given to sugar cane; the other chief crops are manioc, sweet potatoes, and bananas. The principal exports are sugar, molasses, and rum. In 1899, the value of the exports of the island amounted to 26,600,000 francs. Population 187,690, but only 12,000 are whites.

Martius (*mart'se-ŏs*), **Karl Friedrich Philipp von,** Bavarian traveler and naturalist, was born April 17, 1794, at Erlangen, Germany. He studied medicine, and spent three years in Brazil as a member of a scientific expedition sent out by the Austrian and Bavarian governments. His researches on this expedition gained him a reputation second only to that of Humboldt. These researches were published after he reached home — one book on the journey, and several on the cryptogams, palms, and other plants of Brazil, on the medicine of the Indians, and on the races and languages of that region. For thirty-eight years he was professor of botany at Munich. Martius died at Munich, Dec. 13, 1868.

Mar'tyn, Henry, a missionary martyr, was born at Truro, England, Feb. 18, 1781, and studied at Cambridge university. Here he took high honors and at first wished to study law, but becoming fired with missionary enthusiasm, he sailed in 1805 for India as a chaplain of the East India company. At Serampore, Dinapore, and Cawnpore, in spite of broken health, he eagerly mastered the native language, then translated the whole New Testament into Hindustani and Persian, as well as the prayer book into Hindustani, and the Psalms into Persian; and next his zeal rising as the sands of his time ran swiftly out, sailed to Bushire, then traveled to Shiraz, Tabriz, Erivan, Kars, Erzerum, and Tokat, in Armenia, where he sank, worn out by fever, Oct. 16, 1812. See his *Life* by Sargent, and also by Wilberforce.

Marx, Karl, German socialist, was born at Trèves, Prussia, May 5, 1818. It was at first intended that he should be a lawyer, like his father, but at the universities at Bonn and Berlin he gave most of his time to the study of history and philosophy. In 1842, he became editor of a democratic newspaper, the *Rhenish Gazette*. After writing for some time for this journal, he felt that his knowledge of economic subjects needed enlarging, and so in 1843 went to Paris, then the headquarters of socialism. He soon began the course of writing and labor for the advancement of socialism which made up the work of his life. Driven out from France in 1845, he settled in Brussels, where he wrote his attack on Proudhon's philosophy. His chief work at Brussels was the reorganizing of the communistic league, for which he wrote the famous *Manifesto*. Marx took an active part in the revolution of 1848, and after its failure settled in London. In 1859, he published his *Criticism of Political Economy*, which showed a remarkable knowledge of the economic growth of modern Europe. He again became an active worker among socialists and was foremost in founding the International society. After the death of Lassalle he had the practical control of the social democratic movement in Germany. His greatest book, *Capital*, came out in 1867. This book, as also his other works, shows him to have been a man of wonderful knowledge, which he handled with masterly skill, and much more than any other man has he influenced the labor movement throughout the world. Marx died at London, March 14, 1883.

Mary, "the mother of Jesus," is held in high honor by all Christians. Of her life but little is known. It is implied in Matthew that she was of the same family as her husband, Joseph, and so, like him, a descendant of David. She is mentioned but a few times in the New Testament, and almost always with reference to her relations to Christ, as in Matthew i., ii., xii.; Luke i., ii.; John ii., xix., and Acts i., where the last notice of her is of her "persevering in prayer" with the disciples and the holy women at Jerusalem after Christ's ascension. A letter speaks of her as having lived with John at Ephesus, where she died and was buried. Another letter tells that she died and was buried at Jerusalem, at the foot of the Mount of Olives. The story is also told of the apostles coming to her tomb on the third day after her burial, and finding the tomb empty, but breathing out an "exceeding sweet fragrance." In art she is usually indicated by the term "The Madonna"; in ecclesiastical phrase as "Mary the Virgin." The date of her death is commonly fixed at 63 or 48 A. D.

Mary I., queen of England, daughter of Henry VIII. and his first wife, Catharine of Aragon, was born at Greenwich Palace, Feb. 18, 1516. She is usually known as Mary Tudor, and by ultra-Protestants as "Bloody Mary." When a girl she was a great favorite with her father, and when only seven years old was betrothed to the emperor Charles V., and was devoted to her mother and her church. When her mother was divorced, Henry treated her harshly, and during her half-brother Edward's reign she lived in retirement, and no threats could make her conform to the new English church. On the death of Edward, July 6, 1553, Mary became entitled to the crown by her father's will and the settlement made in parliament. The duke of Northumberland had, however, got Edward to set aside Henry's will in favor of Lady Jane Grey, to whom the duke had married his son, Guilford Dudley. Lady Jane was declared queen on July 10, but the whole country favored Mary, who was able without bloodshed to enter London in triumph, August 3. The queen now showed remarkable leniency toward her enemies. Northumberland and two others were put to death; but Lady Jane and her husband were spared. She sought very gradually and carefully to bring back the old religion. A few leading reformers were imprisoned, but there persecution stopped. Queen Mary's reign was ruined by her marriage to Philip II. of Spain. On this her heart was set, even in face of the fears and protests of all England. The proposal caused Wyatt's rebellion and an attack on London. This rising was put down mainly through the courage and coolness of the queen, and at once Jane Grey, who seems to have been held as a sort of hostage for her friends' good-behavior, was, with her husband and father, beheaded. Philip landed and was married to Mary. Cardinal Pole entered England as the pope's legate, and the country became once more Roman Catholic. Then began the persecution which earned the queen the name of "Bloody Mary," when some three hundred victims were burnt at the stake. During this time Mary was almost helpless with ill-health. Philip had left England in 1555, to come back once more only for a few weeks, and grief at her husband's heartlessness helped on her sickness. Finally, Philip brought her to declare war on France, and Calais, the last English foothold on French ground, was lost. Mary died Nov. 17, 1558. See the histories of Froude and Lingard; and *England under the Reigns of Edward VI. and Mary*, by Patrick Fraser Tytler.

Mary II., queen of England. See WILLIAM III.

Mary Mag'dalene, probably so named from Magdala, a town of Galilee, a woman mentioned in Luke VIII. 2, as "Mary Magdalene, out of whom went seven devils," among those that accompanied Jesus. She is held to be the same as the woman "which was a sinner" who, as Jesus sat at meat in the house of Simon the Pharisee, washed his feet with her tears and wiped them with the hairs of her head, and anointed them. She is thought by some to be the same as Mary, the sister of Martha and Lazarus, for which there is little ground. Mary Magdalene stood by Jesus on the cross, and was present when he was laid in the sepulchre. On the first day of the week she came early to the tomb and finding it open ran and told Peter and John that they had "taken away the Lord out of the sepulchre." The three approach and see the two angels, "one at the head and the other at the feet where the body of Jesus had lain." Just after, Christ appears to her and announces His coming ascension. The story that she passed her last days in the desert in penitence for her sinful life has been made the subject of paintings by Guido, Correggio, Canova, and other great masters.

Mary Queen of Scots ("Mary Stuart") was the daughter of James V. of Scotland and Mary of Lorraine, daughter of the French Duke of Guise. She was born at Linlithgow, Scotland, Dec. 8, 1542. Her misfortunes may be said to have begun with her birth. The news reached her father on his deathbed. "The devil go with it!" he muttered, as he thought of the marriage with the daughter of Bruce, which brought the crown to the Stuarts—"it cam with ane lass and it will pass with ane lass." Mary, on the death of her father, James V., became a queen before she was a week old, and was crowned at Stirling Castle, Sept. 9, 1543. Within a year the regent Arran had promised her in marriage to Prince Edward of England, and the Scotch parliament had declared the promise null. A war with England followed, and the Scots were badly defeated at Pinkie Cleuch. But hating

an English match more than ever the young queen was offered and accepted in marriage

MARY QUEEN OF SCOTS.

to the eldest son of Henry II. of France. A French fleet carried the six-year-old girl to France where she was betrothed to the dauphin. Her next ten years were passed at the French court, where she was taught with the king's children. At the age of sixteen she was married to the dauphin Francis, who was six weeks younger than herself. In 1559, Francis came to the throne and for a year and a half Mary was queen of France. When the feeble and sickly Francis died, Mary cared little to stay at a court now ruled by the queen-mother, Catharine de Medici, whom she had taunted with being a "merchant's daughter"; and her presence was needed, too, in Scotland, for her mother had just died and the country was without a government and torn by the struggle of the Reformation. Mary landed at Leith in 1561, after escaping the English ships which Elizabeth had sent to capture her. The Reformation claimed to have been sanctioned by the Scottish parliament and the new queen was content to leave affairs as she found them, only claiming the liberty to use her own religion. Many schemes for Mary's marriage were brought forward. The kings of France, Denmark, and Sweden, the Archduke Charles of Austria, Don Carlos of Spain, the dukes Ferrara, Nemours, Anjou, Arran, and Leicester, were proposed as suitors. Mary herself preferred Don Carlos, the heir of the greatest kingdom in Christendom, but when all hope of getting him was quenched, she suddenly, in 1565, married her cousin, James Stuart, Lord Darnley. Darnley was a great-grandson of Henry VII. of England, and was thus among the nearest heirs of the English crown; but though good-looking, he was weak and vicious, his house had few friends and many enemies in the country, and he was a Catholic. This marriage caused the earl of Moray, the queen's natural brother and her chief minister, to head a Protestant rising; but the revolt was quelled by Mary taking the field in person and driving the rebels beyond the Tweed.

Mary soon became disgusted at Darnley's worthlessness and alarmed at his ambition. He had been given the title of king, and now claimed that the crown should be secured to him for life, and to his heirs, if the queen should die childless; and what Mary refused as a favor he prepared to take by force. Mary's chief minister since Moray's rebellion had been David Rizzio, a common-looking Italian, of brains and accomplishments, but generally hated as a low-born foreigner and a court favorite. The king and Rizzio had been sworn friends, sharing the same table and even sleeping in the same bed; but the king was now persuaded that it was Rizzio that stood between him and the crown. So a conspiracy was formed by the king and Moray and other Protestant leaders, they binding themselves to secure the crown to him and his heirs, and he agreeing to get them pardoned for their late rebellion. The result of this conspiracy was the murder of Rizzio, March 9, 1566, Darnley leading the way into the queen's cabinet and holding her in his grasp while the murderers dragged the poor Italian into an ante-chamber and mangled his body with over fifty wounds. When Mary heard what had been done she broke into loud upbraiding of the king. "I shall be your wife no longer," she told him. But when Darnley on his own authority dismissed the parliament which was about to bring Moray and the other defeated rebels to trial, Mary realized the purpose of the conspirators and set to work to defeat them. By her blandishments she succeeded in detaching Darnley from the others, persuaded him to escape with her from their power by a midnight flight, and to make proclamation denying all connection with their designs. This ended the conspiracy and the king was hated by both sides, as he had betrayed both. In January, 1567, he was taken sick with the smallpox, at Glasgow. Mary went to him and brought him to Edinburgh, where he was lodged in a small mansion. There Mary visited him daily and slept for two nights in a room below his bedchamber. Sunday evening, Feb. 9, she passed by his bedside, talking kindly and cheerfully with him. She left him between 10 and 11 o'clock, and about two o'clock in the morning the house in which the king slept was blown up by gunpowder, and his lifeless body found in the neighboring garden. The chief murderer was undoubtedly the earl of Bothwell, who had enjoyed a large share of the queen's favor since Moray's revolt. But the queen was also suspected, for within three months of Darnley's murder, Bothwell was acquitted at a mock trial, was divorced from his wife of only a year, was made duke of Orkney, and married the queen.

This fatal step at once arrayed the nobles in arms against Mary. Her army melted away without striking a blow and she was forced to give up the throne to her son, James VI., who was crowned July 29, 1567.

The next year, escaping from prison, she found herself in a few days at the head of an army of 6,000 men, only to be defeated at Langside, near Glasgow (May 13, 1568), by the regent Murray. Four days later, Mary crossed the Scottish borders and threw herself on the protection of Queen Elizabeth, only to find herself a prisoner for life. Mary, as the great-granddaughter of Henry VII., claimed the right of succession to the English throne. A good part of England was still Catholic and looked to Mary to restore the old faith. Of the many plots formed for her deliverance, the most famous was the one of Antony Babington, which included the assassination of Elizabeth. It was discovered; certain letters of Mary, approving the death of the English queen, came into the hands of the ministers, and Mary was brought to trial in September, 1586. She was sentenced to death in October, but Elizabeth could not find courage to sign the death-warrant till February, 1587. On the 8th, at Fotheringay Castle, in Northamptonshire, Mary laid her head on the block with the dignity of a queen and the courage of a martyr.

Mary's beauty and accomplishments are world-famous. She was admitted by everyone to be the most charming princess of her time. She was queenly in appearance, on the throne, in the dance, or on horseback at the head of her army. The charm of her soft, sweet voice is said to have been irresistible; and she sang well, accompanying herself on the harp or lute. Her manner was sprightly, affable, kindly, and frank. Her rather large features were lighted up by a winning vivacity and a high, joyous spirit. The starlike brightness of her eyes — whether hazel or dark gray we know not — her fresh, clear complexion and hair of ruddy yellow changing with her years to auburn, then to dark brown, turning gray long before its time, added their share to the beauty that bewitched French, English, and Scotch alike. Two women only, Cleopatra and Helen of Troy, share with Mary Queen of Scots the power wielded over the imaginations of men of all times and countries. See G. Chalmers' *Life of Mary Queen of Scots*, and Miss Strickland's *Lives of the Queens of Scotland.*

Maryland (*măr'i-land*), one of the thirteen original states of the Union, covers a land surface approximately of 9,860 square miles — about the size of Holland. Its greatest breadth from north to south is 120 miles, and its greatest length from east to west is 196 miles. "Mason and Dixon's Line" bounds it on the north and east. The eastern shore of Maryland is the part east of the Chesapeake bay. The western shore reaches from the Chesapeake to the state boundary, the Potomac river. The northwest part of the state is rugged and mountainous; the Blue Ridge and other Allegheny ranges cross it from Virginia and West Virginia into Pennsylvania. The center of the state is hilly, and the east and southeast low. A line drawn from the mouth of the Susquehanna to the city of Washington will divide the high and low lands of the state into nearly equal parts. The main rivers are the Potomac, Patuxent, Severn, Patapsco, Susquehanna, and Choptank. Marl, fine brick clay, gneiss, granite, limestone, iron, and large veins of the finest soft coal are found. Zinc and copper are also mined. Many kinds of marble are quarried, some of them very fine and equal to Italian marbles; the marble used in building the White House came from Maryland. Except on the mountains in the west and in the marshes along the eastern coast, the soil is fertile. Pine, chestnut, and oak are the main trees, though there are still left in the woods, hickory and walnut. The peach orchards cover thousands of acres, and canning fruit is a leading industry; Maryland canned peaches are exported to all parts of the world. The main crop in the peninsula between the Chesapeake and the Potomac is tobacco. Maryland ranks as the seventh state in the growth of tobacco, and at one time the crop of Prince George county was the largest in the Union. Corn, wheat, oats, potatoes, hay, and fruits are the other leading crops. Chesapeake bay abounds in fish, and Maryland bass, moccasin, white perch, sheepshead, herring, and mackerel are excellent. The oyster beds are of great value, and cover large areas in the ocean inlets. Canvasback ducks and other game birds are hunted on the shores of the bay, and here terrapin are found in perfection. The manufactures of Maryland exceed $100,000,000 yearly. Iron and steel, shipbuilding, machinery, pig iron, tobacco and cigars, straw hats, millinery, and cotton duck are some of the leading manufactures. There is now considerable production of fruit brandy and distilled spirits; in Allegany county there is also much coal mined. The famous National road was built early in the century for a highway between Baltimore and Ohio. The pioneer Baltimore and Ohio railroad was organized in 1827. The first American telegraph line was built from Baltimore to Washington in 1844. There are two canals in the state — from Cumberland in the west to Washington, 184½ miles, and between Chesapeake and Delaware bays, 12½ miles.

Maryland has a good school system, and a number of colleges, among them Washington college, to which George Washington gave $500, and Johns Hopkins university, one of the foremost in the country. The other institutions for higher education in the state include Western Maryland college; St. John's college, Annapolis; Loyola and Morgan colleges, Baltimore; New Windsor (Presbyterian) college: and Rock Hill and St. Charles (Roman Catholic) colleges. Maryland sends six representatives to congress. Its general assembly is made up of two houses — the senate

and the house of delegates. The capital is Annapolis (population 8,402), the seat of the United States Naval academy.

Cecil Calvert — Lord Baltimore — received a grant of Maryland, together with parts of Delaware and Pennsylvania, from Charles I. in 1632. He named his new possession in honor of Henrietta Maria, queen of England. Leonard Calvert led the first party of emigrants, made up of English gentlemen, their retainers and servants, which landed on the banks of a branch of the Potomac in March, 1634. The Indians were paid for their land, and were never very troublesome to the colonists. Calvert was himself a Catholic, but people of all beliefs were allowed to worship without persecution. During the civil war in England an engagement was fought at Providence, Md., in 1655, between sympathizers of the two English parties, in which fifty were killed or wounded. This was the first land battle between English-speaking men in America. Maryland was one of the first colonies actively to engage in the Revolutionary war. In the Civil war, Maryland, though a slave-holding state, did not secede. Its chief city is Baltimore (population 508,957), which see. Population 1,190,050.

Masaccio (*mä-sät'chō*), a Florentine painter, whose real name was "Tommaso Guidi," was born in Tuscany in 1401 or 1402, probably at Castel San Giovanni, in the valley of the Arno, Italy. Masaccio means "Slovenly Tommy," a nickname given him because of his ungainliness and careless habits. While still a young man he seems to have painted a fresco of the *Crucifixion* and scenes in the lives of the saints, in the Church of St. Clement at Florence. But his greatest achievements are on the walls of the Carmine (Brancacci) Chapel. Masolino worked at the same walls before him and Filippino Lippi after him, and it is not certain exactly which pictures were from Masaccio's brush. Those which seem his without doubt are *Expulsion from Paradise* — greatly admired by Raphael, *Peter and the Tribute Money*, *Temptation of Adam and Eve*, *Peter Preaching*, and also *Baptising*, *Healing the Sick*, *Giving Alms*, and *Restoring the Young Man to Life*. These famous pictures marked an advance in Italian art and greatly influenced later painters. Masaccio left Florence in 1428, and is said to have gone to Rome and there died in 1429.

Masaniello (*mä-sä-nē-ĕl'lo*), rightly "Tommaso Aniello," a fisherman of Amalfi, Italy, was born about 1622, and became a Neapolitan insurrectionist and the leader of the revolt which took place in Naples in July, 1647, against the Spanish viceroy, the duke of Arcos. The people had already been maddened by oppression and were now greatly excited over a new tax on fruit. A quarrel between the fruit-sellers and the hated tax-collectors drew a crowd into which Masaniello, who was a favorite of the people, ran shouting: "No taxes, no taxes! Long live the king of Spain! Down with the bad government!" Made their chief on the spot, he led them through the streets, tearing down the tax-gatherers' houses, burning palaces, opening prisons, and driving the viceroy into his castle. A government was set up by the citizens, and Masaniello was made captain-general of the Neapolitan people. An attempt of some nobles to kill him only lost them their own lives; the viceroy was obliged to remove the fruit-tax, and to give back to the citizens the privileges bestowed on them by Charles V., and the people were allowed to keep their arms till this agreement should be ratified by the king of Spain. The rising brought to a successful end, the hero of the hour threw off his rich robes and declared himself a fisherman again. But the people would not let him resign. The next day he was a different man; either success or poison had turned his head, and the freedom he had fought for soon gave place to a reign of terror. The people fell away from him, and the viceroy's agents had no trouble to assassinate him at Naples, July 16, 1647. His reign lasted just nine days. Auber's opera *Masaniello* is based on the story.

Mascart (*măs-kär'*), **Eleuthere Elie N.**, an eminent French physicist, born Feb. 20, 1837. Entered the normal school at Paris in 1858, received his doctor's degree in 1864. In 1872, he was appointed professor of physics in the Collège du France. In 1878, he was placed in charge of the meteorological bureau of France. He was elected to the Academy of Sciences in 1884. His principal work is along the line of atmospheric electricity, optics, and terrestrial magnetism. As a writer of treatises on these subjects he has rendered important service to science.

Mashonaland (*ma-shō'-na-lănd'*), Africa, is the region northeast of Matabelaland. It includes the plain — 4,000 to 4,600 feet high — whose backbone is formed by the Umvukwe mountains. It is said to be the healthiest part of South Africa, with rich soil, grass all the year round, and many running streams. The Matabele have driven the Mashona to the mountains, where they have built their villages on almost inaccessible crags. A peaceful and industrious people, of the Bantu race, they live in the greatest fear of their fierce neighbors. They raise rice, Kaffir corn, Indian corn, groundnuts, sweet potatoes, tobacco, and cotton, which they weave into blankets. Iron, copper, and gold are found in large quantities. Mauch, a German traveler, discovered many old mines which at one time had been skillfully worked, especially at a place called Zimbabwe, which he thought the same as the Ophir of the Bible. Mashonaland became a British protectorate in 1888. With Matebelaland, Mashonaland has since then been organized by the British South

African company, under the Hon. Cecil Rhodes, and is now named Southern Rhodesia. The capital is Salisbury (population about 2,000), which is now reached by a railway line from Bulawayo, thence south to the Cape. See Montagu Kerr's *The Far Interior*, *The Ruined Cities of Mashonaland*, by Bent; *Rhodesia of To-Day*, by Knight, and *How We Made Rhodesia*, by Lenard.

Ma'son and Dix'on's Line, often thought to be a line dividing the slaveholding states from the free states. In fact, it ran for over one-third of its length between two slave states, Maryland and Delaware. It was run by two English surveyors, Charles Mason and Jeremiah Dixon, during the years 1764 and 1767, and determines the boundary between Maryland and Pennsylvania, and between Maryland and Delaware. Milestones were set up, and each five miles marked by a larger stone, on which were cut the arms of William Penn and Lord Baltimore. The work was so well done that when, in 1849, it was gone over again no mistake of any account was found. The line does roughly divide the north from the south, and is popularly used to distinguish the two sections of the country.

Ma'son, George, was born at Doeg's Neck, Va., in 1725. In 1775, the Virginia convention made him a member of the committee of safety which was charged with the government of the colony. The next year he drew up a declaration of rights and a constitution for the new state, which were both adopted without an opposing vote. He also, with the help of Jefferson, had a bill passed making all kinds of worship lawful in Virginia. In 1777, he became a member of the Continental congress. In 1787, he was one of the foremost men in the convention which drew up the constitution of the United States, where he took firm ground against making slavery permanent in the country. He was afraid that the constitution, as at last agreed upon by the convention, would bring about a monarchy or a tyranny of aristocrats, and stood shoulder to shoulder with Patrick Henry in fighting its ratification by Virginia. He sought to have about twenty changes made, some of which were afterward adopted by congress. He was chosen as Virginia's first United States senator, but refused to serve. His statue stands with Jefferson's, Henry's, and those of other leading Virginians at the base of Crawford's statue of Washington in front of the capitol at Richmond. Mason died in Fairfax county, Va., in 1792.

Ma'son, James Murray, an American jurist and statesman, and also commissioner from the Confederate States to England in 1861, was born in Fairfax county, Va., Nov. 3, 1798, being a grandson of George Mason, an intimate friend and a near neighbor of Washington. He graduated from William and Mary college in his young manhood, and was admitted to the Virginia bar when twenty-two years of age. He served many years in the Virginia house of delegates and in the Federal congress from 1837 to 1839. He was elected senator from Virginia in 1847, and retained that place until the breaking out of the Civil war, when he withdrew from the senate and cast in his lot with the seceding states. He was captured Nov. 8, 1861, when on his way to Europe to represent the Confederacy abroad, and was held a prisoner by the Federal authorities until Jan. 1, 1862, when, upon the demand of the English government, he was released. His mission to England, after all, proved ineffective, although it came near embroiling the two nations, England and the United States, in war. Mr. Mason died near Alexandria, Va., April 28, 1871.

JAMES M. MASON.

Ma'son, Jeremiah, was born at Lebanon, Conn., April 27, 1768. He graduated at Yale in 1788, and studied law. He then went to New Hampshire, where he became the state's attorney-general and the acknowledged head of the New Hampshire bar. In 1813, he was chosen United States senator, and took a leading part in the debates on the embargo, conscription bill, and other questions of the War of 1812. He moved to Boston in 1832, where he practiced law till his retirement in 1838. As a lawyer he ranked with such men as Judge Story and Daniel Webster. He died at Boston, Oct. 14, 1848. See his *Life*, by Ellis.

Ma'son, Lowell, an American composer, was born at Medfield, Mass., Jan. 8, 1792. As a boy he was very fond of music, and began to teach it when quite young. In 1821, his *Boston Handel and Haydn Collection of Church Music* was published, and at once made him noted, and enabled him to leave Savannah, where he had taught for fifteen years, and make Boston his headquarters. Here he taught children's classes without charge, and published a number of music books for children, as well as glee books, and over twenty books of sacred and church music. A large part of the best American church music is Mason's. He died at Orange, N. J., Aug. 11, 1872.

Mass is the name which has been given to the amount of matter in a body. The mass of a body, the amount of matter in a body, and the inertia of a body, are strictly synonymous terms as used in modern physics.

Matter, and therefore mass, has not been defined in terms of anything simpler; but mass can be measured in terms of many other quantities. Thus mass is equal to the product of volume by density. In like manner, the mass of a body is equal to the quotient of its weight divided by the acceleration of gravity. A sharp distinction between *mass* and *weight* is essential to all clear thinking on this subject.

The standard of mass used in ordinary commerce is the mass of a piece of metal kept in the Standard's Office in London and known as the Avoirdupois Pound. The standard of mass employed in science is a piece of metal kept at the International Bureau of Weights and Measures at Sèvres, and known as the kilogramme. See INERTIA.

Massachusetts (*mas'a-chū'sĕts*), one of the New England states, and one of the original thirteen states. It is 47½ miles wide and 182 miles long, being but one-sixth as large as New York, and lies between the Atlantic ocean and New York state. The Green mountains of Vermont extend into the state in the western part in two ranges, with no very high peaks, Greylock, 3,505 feet high, being the highest; and the coast is lined with highlands. The valleys of the Housatonic and Connecticut rivers are fertile, but the higher parts of the state and the long sandy coasts are poor soil. The rivers, such as the Merrimac, Connecticut, Housatonic, and Concord, are useful mainly as furnishing water-power for the numerous factories of the state. Cape Cod is a sandy point, 65 miles long, shaped like a bent arm, inclosing Cape Cod bay, and making, with Cape Ann, Massachusetts bay, on the Atlantic coast. Martha's Vineyard and Nantucket are large islands off the coast. The scenery of the western part of the state, especially of Berkshire county, is very beautiful, and it is sometimes called the "Switzerland of America." Granite, sandstone, limestone, and hematite are the chief mineral productions of the state, but its agriculture is not equal to supplying the demands of its people, as it is the least agricultural state in the Union, only nine per cent. of its laborers being employed on farms. Its great source of wealth is its manufactures. Wire drawing was begun in the colony in 1666, and the manufacture of iron and steel wire is still a very large industry. The oldest watch factory in the United States, and the largest in the world, is at Waltham. The many shoe factories in Lynn, the great cotton mills in Lowell, Lawrence, Fall River, and New Bedford, are well known.

Shovels, belting, clothing, silverware, books, woolen and silk goods, chocolate and confectionery, carpets, furniture, carriages, and paper, are a few of the many useful articles produced in Massachusetts. The fisheries of Massachusetts are very valuable, and the shipping trade of Boston is next to that of New York. Massachusetts was one of the first states to build railroads. The Hoosac tunnel, one of the first long tunnels, cut for five miles through the Hoosac mountain, costing $16,000,000, and taking 20 years to build, was undertaken by the state. The school system is one of the finest in the country, and such institutions as Harvard university, with its 14,000 graduates; Boston university, with schools of art, music, agriculture, law, theology, and medicine; Clark university, at Worcester, for the higher special work of college graduates; Massachusetts Institute of Technology; the State Agricultural college at Amherst, Andover Theological seminary, Newton Theological institute; Amherst, Williams, Tufts, and the Catholic Boston college, are some of the best-known institutions. Radcliffe college for women was founded in 1879, Wellesley college, near Boston, and Smith college at Northampton, and Mt. Holyoke seminary and college, the earliest school of the kind for women in America, are among the ample provisions made for the higher education of women. Music and art are recognized in the New England Conservatory of Music at Boston, Art Tile works at Chelsea, Boston Museum of Fine Arts, and many art schools. There are over 500 public libraries in the state, the largest being in Boston, Worcester, Cambridge, Springfield, etc., besides the large libraries of the colleges and the Boston Athenæum.

The earliest discovery of the land embraced in Massachusetts is thought to have been made by the Norsemen, about the year 1000, and later, in 1497, the Cabots reached its coast. But the landing of the Pilgrim fathers at Plymouth, Dec. 22, 1620, is the date of the first settlement. The stone on which they landed is carefully guarded at Plymouth. Other settlements were made later, forming the Massachusetts Bay Colony. The colonists endured great privations, and suffered terribly in the Indian wars. The government, at first, was in the hands of the colonies, and was carried on with Puritan vigor; but in 1692, the country was ruled by a governor appointed by the king. The first battles of the Revolutionary war were fought on the soil of Massachusetts, at Lexington and Bunker Hill, and the troops of Massachusetts were among the earliest on the field in the Civil war. Population 2,805,346. See *History of Massachusetts*, by Barry; *History of New England*, by Palfrey.

Massachu'setts Indians. Massachusetts when first settled was occupied by five Algonquin tribes, the Pennacooks, the Massachusetts, the Nausets, the Pokanokets, and the Nipmucks. These tribes were all friendly, save the Nausets, with whom Plymouth made a treaty of peace. Missions among the Indians were begun by the Mayhews, of Martha's Vineyard, in 1644, and by John Eliot two years later. After five years' work among

them, Eliot gathered the "praying Indians," as the converts were called, at Natick, and translated the Bible into their language. By 1674, the praying Indians numbered 3,200. The next year King Philip's war broke out, which began with the rising of the Pokanokets under their chief, Philip, and spread to the Nipmucks, Massachusetts, and Pennacooks. The frontier settlements were ravaged; the praying Indians were attacked by both reds and whites, and the savages were not conquered nor the war ended until the death of Philip in 1676. Many Indians were sent as slaves to the West Indies; the Pennacooks mostly joined tribes eastward, or in Canada; the others quieted down, and were given lands from time to time. They have since mostly intermarried with whites or negroes, and there are now less than a hundred full-blooded Indians in the state. See Abbott's *History of King Philip;* Moore's *Life of John Eliot.*

Massasoit (*mas'sa-soit*), a chief of the Pokanoket or Wampanoag Indians, ruled over most of south Massachusetts from Cape Cod to Narragansett bay. His tribe, once some 30,000 in number, shortly before the landing of the English had lost all but about 300 by a disease, probably the yellow fever. In 1621, three months after Plymouth had been founded, Massasoit and sixty warriors, armed and painted, came to the settlement and made a treaty of peace. This treaty was kept for fifty years, and Massasoit was always friendly to the settlers. His home was where now stands the town of Warren, R. I., and here he entertained Roger Williams for several weeks, when on his way to Providence after being banished from Massachusetts. Massasoit was honest, kept his word, and loved peace. He died in 1661. His son Pometacom, on his father's death, went to Plymouth and asked to be given an English name. He was named Philip, and became the leader of King Philip's war.

Massena (*mă-sā-nä'*), **Andre,** duke of Rivoli, prince of Essling, and the greatest of Napoleon's marshals, was born at Nice, Italy, probably of Jewish parents, May 6, 1758. He began life as a cabin boy, and served fourteen years in the Sardinian army. Early in the French revolution, he joined a battalion of volunteers, and rose quickly in rank, becoming in 1793, a general of division. He distinguished himself greatly in the campaigns in upper Italy, especially at Saorgio, Loano, and Rivoli, and earned from his commander his famous name of "Dear Child of Victory." After Jourdan's defeat at Stockach, in 1799, Masséna was given command of the army in Switzerland and by his crushing victory over Suvaroff's Russians at Zurich in September freed France from the danger of invasion. In 1804, he was made a marshal of the empire and commander of the army in Italy. He kept the Archduke Charles of Austria in check, crushed him at Caldiero, and overran Naples. During the peace that followed the campaign of 1807 he lost his left eye by an accident at a hunting party. In the campaign of 1809 against Austria, he commanded on the right bank of the Danube river and covered himself with glory at Landshut, Eckmühl, and Ebersberg-on-Traun. On the second day of the battle at Aspern, or Essling, with the greatest bravery he covered the retreat of the army across the Danube, and perhaps saved it from destruction, earning the title of prince of Essling. In 1810, he was sent to Spain to drive out the English, and drove Wellington back upon his intrenchments, at Torres Vedras. Finding it impossible to break the English lines, and harassed by lack of supplies, he made a masterly retreat, but was recalled in anger by Napoleon. He himself said his failure was owing to the disobedience of his captains Ney and Junot. However, he offered his services again when the emperor was making ready for the Russian campaign, but was only given a command in Provence. He submitted to the Bourbons at the restoration, and was made a peer. He refused to join Napoleon on his coming back from Elba, but also refused to sit on the court-martial of Marshal Ney. In strategy and tactics, Masséna was like Napoleon in quickness and ability, and was brave and unwearied on the battlefield. He died at Paris, April 4, 1817.

Massillon (*mă'sil-lŏn* or *mă-sē-yōn'*), **Jean Baptiste,** one of the greatest of French clerics and modern orators, was born at Hyères, in Provence, France, June 24, 1663. His father was a notary and wished Jean to become one too, but nothing could keep him from entering the service of the church. His power as a preacher was soon found out, and his funeral oration on the archbishop of Vienne won him fame and brought him to Paris, where he heard Bourdaloue, whose style and manner greatly influenced him. He first preached before Louis XIV. in 1699. It was to him that the king said: "I have heard great orators in my chapel and have felt satisfied with them, but every time I have heard you I have felt dissatisfied with myself"—a saying which shows the fearless eloquence of this great orator. In 1717, Massillon was made bishop of Clermont, and next year preached his famous series of ten short sermons for Lent before the young king, Louis XV. His last public discourse in Paris was his funeral oration on the duchess of Orleans in 1723. From this time he lived almost wholly for his bishopric, where his charity and gentleness gained him the love of all. He died Sept. 18, 1742. Bossuet and Bourdaloue rival him in oratory, but he was a greater preacher than either. Among his masterpieces are his sermons on the *Prodigal Son*, on the *Death of the Just and the Unjust*, and his sermon *For Christmas.*

Massillon (*măs'il-ŏn*), **O.**, a city in Stark county, in northeast Ohio, on the Tuscarawas river, the Ohio canal, on the Lake Erie, Pennsylvania, and Wheeling, and Cleveland, Lorain, and Wheeling railroads. It lies 65 miles south of Cleveland, is a good wheat-growing and nib coal-mining, and stone-quarrying belt. It has many industries, including iron-bridge, agricultural-implement, and threshing-machine works; paper, flour, and rolling mills; sandstone quarries, glass works, etc. It possesses some good schools, churches, banks, and public buildings. Population 11,944.

Massinger (*mas'in-jer*), **Philip,** an English dramatist, was born at Salisbury, England, in 1584. He studied at Oxford, 1602. In 1606, he went to London and is reported to have entered the Roman communion. Eighteen of his plays are still extant, the earliest being the *Virgin Martyr*, published about 1622. Notwithstanding his genius and the popularity of his plays, he lived in obscurity; and the course of his life in London is not easily traced. Among the works of Massinger that are best known may be mentioned *Duke of Milan*, *Fatal Dowry*, and *A New Way to Pay Old Debts*, which latter is still in use upon the stage. Fletcher and Decker were associated with him in the production of certain of his works. He was found dead in his bed March 16, 1640, and buried March 20, being entered upon the book of the parish church simply as "A Stranger."

Mas'todon, a large fossil elephant, remains of which are found abundantly in marshes and bogs in both Europe and America. In Kentucky, the bones of one hundred mastodons and twenty elephants were dug out of one bog. They have been found abundantly in New York, New Jersey, Indiana, and Missouri. Several very perfect specimens have been obtained from New York. Their bones are more massive than those of the elephant. These had attracted the attention of the Indians, who named the beasts to which they belonged "Fathers of Oxen." The mastodons were very large, being twelve or thirteen feet high, and including the tusks, twenty-four or twenty-five feet long. Their grinding teeth were provided with large rounded points like nipples, from whence came the name mastodon (Greek, *mastos*, the breast, nipple, and *odous*, tooth). Twigs of spruce and fir have been found lodged in the teeth, and, also, in considerable masses within the ribs where the stomach was situated. They seem to have become extinct in Europe at the close of the Tertiary period, while in America they lived through the Quarternary in association with primitive elephants. During the latter period of geological time those large beasts roamed in herds over North America, from the Gulf to the Arctic regions, in company with other representatives of the elephant tribe. See MAMMOTH.

Mastiff. See DOG.

Matabeleland (*măt'a-bē'le-land*), is the name given to a somewhat indefinite region lying north of the late South African Republic, the Transvaal, and estimated to contain over 60,000 square miles. North of it lies Mashonaland; east of it, the Portuguese east African possessions, and west of it German southwest Africa. The Zambesi river may be considered its northwest boundary. It used to be described as "part of Kaffraria"; but now it forms a part of what is called "Rhodesia." Its population is supposed to be in the neighborhood of 155,000, mostly natives. Its plateaus are well adapted to agriculture and admirably fitted for European settlement. It is supposed to be rich in mineral resources. About 5,000,000 acres have been surveyed; and at the capital, Bulawayo, there are several hotels, banks, and government offices. Two or more newspapers are published here. Bulawayo is also the center of considerable railway building, a line connecting it with Vryburg on the south, opened for traffic in November, 1897; and a section extending 150 miles to the north would have been opened in 1900 but for the war in the Transvaal. A line is laid out through Gwelo to the Zambesi, and northward to Lake Tanganyika. The native population is a branch of the Zulus, physically among the finest of the African races. They formerly lived far to the south, occupying part of the present territory of the Transvaal, but they removed to their present site about 1830. In 1879 the British broke up the confederacy of the Zulus by a hard-fought war; and in 1893 the South African company gave to the Matabeles a crushing and decisive defeat, from which they have never recovered. Matabeleland, on account of its fertile soil, temperate climate, and mineral resources, promises to be one of the most important links in the colonies which Great Britain is prepared to stretch from the Mediterranean to the Cape of Good Hope.

Matamoros (*mă-tă-mō'rŏs*), **Mariano,** a Mexican priest and patriot. Nothing is known of the time of his birth or of his early life. At the time of the Mexican revolution in 1811, he was parish priest of Jantelolco, a village south of Mexico. Here he was threatened by royalist troops and fled to Izucas, where he joined the rebels. Their chief, Morelos, at once made him a colonel, and he quickly became a popular leader and an able officer. In the defense of Cuantla the credit was given by Morelos, but was really due to Matamoros. He took part in the expedition to Oajaca, and won the victory of San Augustin del Palmar. The revolution had now triumphed over all Mexico, except in a few of the larger cities, but the cause was endangered by Morelos' hasty attack on Valladolid and rash battle of Puruaran. In this battle Matamoros was cap-

tured and was speedily executed, Feb. 3, 1814. The temporary failure of Mexican independence was probably due to the death of this patriot, whose memory is highly honored by the Mexicans.

Matanzas (*ma-tăn'zas*), a fortified town and seaport on the north coast of Cuba, 55 miles by rail east of Havana. It is the third largest city in Cuba, in a very rich district, with a good harbor. It has a large trade in sugar, molasses, rum, and cigars, and has several distilleries and iron foundries. Population 37,760.

Match'es, the name now given to splints of wood tipped with some composition (usually containing phosphorus), to produce light by friction. They came into general use about the year 1834. Before that time, light was produced by striking steel with a flint and catching the sparks on tinder (charred cotton). A flame was obtained by touching the burning tinder with punk, or strip of wood tipped with sulphur. Savage races sometimes obtain light by rubbing two bits of wood together. Other devices employed formerly were a lens to concentrate the sun's rays on some inflammable substance; a lamp for producing a jet of hydrogen gas, and kindling it by making it play on spongy platinum; a splint tipped with a mixture of chlorate of potash and sugar, which took fire on contact with sulphuric acid, and the lucifer match, invented fifty years ago, tipped with a paste of chemicals, which would take fire when drawn with a good deal of pressure across sandpaper. Phosphorus, introduced in 1834, was a great improvement. The chief operations in the manufacture of matches are: 1. Cutting the wood splints. 2. Immersing the splints in melted paraffine, or sometimes in sulphur. 3. Preparing the igniting composition and dipping the splints into it. Matches are made of pine or aspen wood. This is sawed into blocks, which are then forced endwise through thick steel plates full of little holes, with sharp edges, and just the size of a match. The splints thus formed are then fed by thousands to dipping frames by filling machines (of which there are several kinds, and of American invention). In the dipping room the igniting composition is spread on a hollow iron table, kept hot by steam, and the splints are dipped into it. Nearly every manufacturer has his own special mixture for the dipping of matches, and phosphorus is an important element in all of them; but in the case of so-called safety matches there is phosphorus only on the prepared surface upon which they are ignited. Match making is an important industry in the United States, Great Britain, France, Germany, Sweden, and Norway.

Mather (*măth'er*), **Increase,** was born at Dorchester, Mass., June 21, 1639. He graduated at Harvard in 1656, and at Trinity college, Dublin, two years later. He entered the ministry and preached in Devonshire and Guernsey before going back to America. From 1664 until his death he was pastor of the North Church at Boston. From 1685 to 1701 he was president of Harvard college and was the first minister in America to receive the degree of doctor of divinity. When, in 1684, Charles II. annulled the charter of the colony, Mather was sent to England as the agent of Massachusetts. Unable to get the old charter restored, he took back in 1692 a new one, under which the naming of the crown officers was left to him. A day of thanksgiving was appointed for his safe return and the success of his mission. Mather studied sixteen hours a day, always gave a tenth of his income in charity, and in every way was a man of careful habits. He was also one of the earliest of American writers. Of his many works, perhaps the best known is his *Remarkable Providences*. Increase Mather died at Boston, Aug. 23, 1723.

Math'er, Cotton, son of the preceding, was born at Boston, Feb. 12, 1663. He graduated at Harvard in 1678. When only fourteen he began a regular system of fasts, which he kept up all his life. Wishing to enter the ministry, he conquered an impediment of speech, and became his father's assistant in the North Church at Boston. He was much interested in civil affairs and drew up the declaration of the colonists justifying the imprisonment of Governor Andros. In 1685, appeared his *Memorable Providences Relating to Witchcraft and Possessions*, which was used as an authority in the Salem witch trials. In 1688, the children of John Goodwin were suspected of being visited by the devil, and Mather, with three other ministers, held a day of fasting and prayer over the cases. His *Wonders of the Invisible World* was written to prove to the world the reality of witchcraft. Both he and his books did much to fan the cruel fury of the New Englanders, and while it is true that the main body of the colonists fully shared his belief, none equaled him in hateful zeal, and on his head rests the heaviest burden of bloodguiltiness. Afterward he confessed that "there had been a going too far in that affair." Both his industry and his learning were remarkable and poured from the press as many as 382 books. Of these the chief is *Magnalia Christi Americana*, a mass of materials for the church history of New England. His *Essays to Do Good* were much liked by Franklin. Cotton Mather died at Boston, Feb. 13, 1728. See Charles W. Upham's *History of the Salem Delusion.*

Math'ew, Theobald, commonly known as "Father Mathew," the Irish apostle of temperance, was born at Thomastown, Tipperary, Ireland, Oct. 10, 1790. He studied for the priesthood and entered the order of the Capuchins. As a Capuchin father at Cork, he found that the poverty and wretchedness of his people

was due in great measure to over-drinking, and he became an earnest preacher of total abstinence. His crusade, begun in 1838, soon spread to Dublin, Liverpool, Manchester, London, Glasgow, New York, and wherever there were Irishmen. His success was marvelous. Each pledge-taker was given a medal, which was looked upon with the greatest reverence, and among the poor it was generally believed that the "Apostle of Temperance" was miraculously aided in his work by heaven. During his last years his unthinking charity brought him to poverty. The enthusiasm for his cause died away amid the sufferings of the potato famine, and Father Matthew died at Queenstown, worn out by his labors, Dec. 8, 1856. See Harriet Martineau's *Biographical Sketches*, and his *Life* by F. J. Matthew.

Matsys (*măt-sis'*), **Quentin,** Flemish painter, was born at Louvain, Belgium, about 1466, and is said to have first been a blacksmith. He settled at Antwerp in 1491 and there died in 1530 or 1531. His pictures are mostly religious, and are remarkable for their glow of color, their absence of light and shade, and their fine finish. The *Burial of Christ*, *Martyrdom of John the Baptist*, and *The Money-Changers* are among his best pictures. Matsys also takes high rank as a portrait-painter. He seems to have been acquainted with Holbein, Dürer, Erasmus, Sir Thomas More, and other noted men of the time.

Matterhorn (*măt'ter-horn*), called by the French Mont Cervin, and by the Italians Monte Silvio, is a peak of the Alps in the Swiss canton of Valais and Piedmont, which rises 14,705 feet high. The peak was first scaled by a party of four Englishmen and three guides, July 14, 1865, when two of the party fell over the precipice and were killed. See Whymper's *Ascent of the Matterhorn.*

Matth'ew (meaning *Gift of Jehovah*), one of the twelve apostles, and held to be the author of the first of the four gospels. He was a publican, or tax-gatherer, at Capernaum, when called by Jesus to follow him. Except in the four lists of the disciples, Matthew is nowhere mentioned by name in the New Testament. An early authority speaks of his having died a natural death; by other writers he is said to have suffered martyrdom after preaching in Parthia and Ethiopia. Papias, a bishop of the second century, tells us that "Matthew wrote in the Hebrew dialect a collection of the sayings of the Lord, and each one interpreted them as best he could."

Matthews (*măth'ūs*), **James Brander,** an American author and professor, was born at New Orleans, La., Feb. 21, 1852. He graduated at Columbia college in 1871; took the degree of bachelor of laws in 1873, and was soon thereafter admitted to the bar. He, however, preferred literary pursuits and gave his whole attention to authorship, becoming one of the founders of the Authors' club. He has published over thirty separate volumes, edited a great many editions of popular works, and contributed numberless articles to the periodicals. Since 1892 he has filled the chair of literature at the college of his graduation. His best-known works are *Americanisms and Briticisms*, *Vignettes of Manhattan*, and *Introduction to the Study of American Literature.*

Matth'ews, Stanley, an American jurist, was born at Cincinnati, July 21, 1824. Graduating at Kenyon college, Gambier, O., he was admitted to the bar in Tennessee, but soon returned to Cincinnati, where he was made one of the editorial writers for the *Herald*, a vigorous antislavery paper with which he was connected for several years. He was successively county judge, state senator, and United States attorney; but March, 1861, he entered the volunteer army, soon rising to the rank of colonel. In 1863, he resigned and became judge of the superior court of Cincinnati. In March, 1877, he was elected United States senator. In 1881, he was appointed by President Garfield one of the associate justices of the United States supreme court. He died at Washington, D. C., March 22, 1880.

Matthias (*măt-tē'ăs*), **Corvinus,** king of Hungary, the second son of the regent John Hunyady, was born at Klausenberg, Hungary, March 27, 1443. On the death of his father, his brother was slain and himself imprisoned by order of Ladislaus, king of Hungary and Bohemia. After the death of Ladislaus he was chosen king (1458), but it cost him a six years' hard struggle against Turks, Bohemians, the Emperor Frederick III., and his own nobles, before he could venture to have himself crowned. He drove the Turks out of his kingdom, in which they had gained a footing, and won from them Bosnia, Moldavia, and Wallachia, before he granted them a truce. This breathing-space he used in making war on his father-in-law, the king of Bohemia, and that king's successor, Ladislaus of Poland. In the midst of this war he had to put down a rebellion of the Hungarian magnates, who offered his throne to Casimir, a brother of Ladislaus. In 1478, he brought the war to a close, getting possession of Moravia, Silesia, and Lusatia. In 1485, a war with Frederick III. ended in the siege and capture of Vienna by Matthias. Vienna was made the Hungarian capital, and a large part of Austria proper fell before the conqueror. The crushing of the Turks, in 1479, at Kenyermezö, by Stephen Bathori, added another to the victories of this reign. Matthias was not merely a conqueror: he founded the University of Budapest summoned scholars and artists to his court, and enriched his capital with the works of the most renowned sculptors. At the same time, wise laws made the country prosperous, and justice was dealt

out to noble and peasant alike. He, however, ruled like a despot, and his taxes were heavy and exacting. Matthias died at Vienna, April 6, 1490.

Mauch Chunk (*mȧk' chŭnk'*), a mining town of Pennsylvania, lies among picturesque hills on the Lehigh river, 90 miles northwest of Philadelphia. There is a switch-back railroad, nine miles long, from the town to Summit Hill, famous for its burning mines, which have been on fire since 1858. Population 4,029.

Mauna Kea (*mou'nȧ kē'ȧ*) on the island of Hawaii, the highest mountain in the Hawaiian islands, and in Polynesia, rises 13,953 feet above the sea. It is a volcanic dome, and its craters have not long ceased their eruptions. Its top is covered with snow most of the year, and herds of wild cattle roam in the woods that cover the mountain-side.

Mauna Loa (*mou'nȧ lō'-ȧ*), a volcanic mountain of Hawaii, 13,760 feet in height. It is wholly made up of lava that has been thrown out in a fluid state. It is a smooth, regular dome in shape, with forests on its flanks at an elevation of 5,000 feet. It has many craters near the top and on the sides, and new ones sometimes open. The top crater, called Mokuaweo-weo, is round in form, and 8,000 feet across, and about 1,000 feet deep. The eruptions are often like lava-fountains, spouting from the top of the mountain. In 1859, one of these fountains for four or five days sent up a stream of white-hot fluid lava, about 200 feet through and 200 or 300 feet high, lighting up the horizon for 150 miles. In 1868, the lavas forced their way for 20 miles underground, and then burst through a fissure two miles long. Here four fountains spouted, sometimes joining in one fountain two miles in length, throwing up crimson lava and red-hot bricks 500 or 600 feet high.

Maurice (*maw'riss*, German *mo'rits*), "elector of Saxony," a German general, was born at Freiberg, Saxony, March 21, 1521. In 1542, he fought under the Emperor Charles V., against the Turks, and the next year against the French. He fought also with Charles at the battle of Mühlberg in 1547, in which the Smalkald league of German Protestant princes was defeated, though its two leaders were his father-in-law, Philip, landgrave of Hesse, and his cousin, John Frederick, elector of Saxony. Though John Frederick's dominions and title were given to Maurice, the fact that he was himself a Protestant, together with Charles' treacherous arrest of the landgrave, and other despotic acts, soon cooled his devotion to the emperor. Ordered to proceed against the rebellious city of Magdeburg, he had an excuse for raising an army under Charles' very eyes. A secret treaty was made with France, and on his demand for his father-in-law's freedom being refused, he suddenly appeared before Innsbruck, where Charles was lying very sick of the gout, in 1552. Charles barely escaped by flight, only to find Lorraine overrun by French troops. By this sudden and successful move, Maurice forced from the great emperor not only the release of Philip of Hesse, but also the treaty of Passau, July 16, 1552, which granted the fullest liberty of worship to Protestants. The next year Maurice headed a league against the margrave, Albert of Brandenburg, who would not acknowledge this treaty, and crushed him at the battle of Sievershausen, near Hanover, but was himself wounded and died two days later, July 11, 1553.

Maurice (*maw'riss*), **John Frederick Denison,** one of the leading thinkers and social reformers of his time, and the son of a Unitarian minister, was born at Normanston, England, Aug. 29, 1805. He studied at Cambridge, then went to London, where he was editor of the *Athenæum* for a time. He entered the Church of England, and in 1837 was appointed chaplain to Guy's hospital. In 1840, he became professor of literature at King's college, London, where he was professor of theology from 1846 till 1853. In 1866, he became professor of moral philosophy at Cambridge. Among his books are, *Prophets and Kings of the Old Testament*, *Gospel of St. John*, and *The Kingdom of Christ*. Maurice was the mainspring of the movement known as *Christian Socialism*, and the president of the society for encouraging workingmen's associations. He was also the founder, at London, of the Workingman's college and Queen College for Women, in both of which he taught. He died at London, April 1, 1872. See *Life of Maurice*, by his son, Colonel Maurice.

Maurice (*maw'riss*), **Prince of Orange** and **Count of Nassau,** one of the most skillful generals of his age, was the son of William the Silent, prince of Orange, and was born at Dillenburg, North Germany, Nov. 14, 1567. After his father's assassination, in 1584, the provinces of Holland and Zealand, and afterward Utrecht and the other Netherland provinces, chose him as their stadtholder. A great part of the Netherlands was still in the hands of the Spaniards; but under the leadership of Maurice the Dutch rapidly wrested cities and fortresses from their enemies. In 1597, he defeated the Spaniards at Turnhout, and in 1600 crushed them at Nieuwport. Then for more than three years he baffled the whole power of Spain by his defense of Ostend. At last, in 1609, Spain reluctantly acknowledged the United Provinces a free republic. A faction fight between the "Orange" party and the "Remonstrants," led by Olden-Barneveldt, was not ended by the victory of the former party till 1621. At once Maurice renewed the war with Spain. He died at The Hague, April 23, 1625.

Mauritania. See MOROCCO.

Mauritius (*maw-rish'-i-us*), or **Isle of France,** an island and British colony in the Indian ocean, 500 miles east of Madagascar. It is of volcanic formation. A girdle of reefs, broken only by passages at the mouths of the small streams, makes it difficult of approach. The surface is a tableland rising into ridges 500 to 2,700 feet high, the highest peak, Rivière Noire, being 2,711 feet above sea level. Lava and basalt rock and volcanic lakes occur. The picturesque beauty of the Isle of France, as the French called it, covered with forests, is described in St. Pierre's *Paul and Virginia*, and Besant and Rice's *My Little Girl*. But in the 19th century, the woods have been cut down to make room for sugar-cane plantations. Among the native trees are the ebony, cocoanut palm, bamboo, benzoin, ironwood, and traveler's tree. There are many tropical fruits, besides food plants, as sugar, vanilla, coffee, cocoa, corn, rice, yams, manioc, etc. Terrific cyclones are common. In 1854, the cholera carried off 17,000 people and thirteen years later 30,000 died of fever. The educated upper classes are mostly descendants of the French colonists. There are a number of negroes, Malagasy, Singhalese, Malays, and Chinese; but the bulk of the people are coolies who have been brought in nearly every year since 1842 to work the sugar-fields. The capital is Port Louis (population 52,517). The great crop is sugar, though large quantities of rum, cocoanut-oil, vanilla, Mauritius hemp, aloe fiber, drugs, and caoutchouc, are also exported. Mauritius is a British colony, and is ruled by a governor and executive council. The island was discovered by Mascarenhas in 1507, who found it uninhabited. The Portuguese abandoned it, and it was seized by the Dutch in 1598, who named it after their Prince Maurice; but they in turn abandoned it in 1710. The French were its next masters, and introduced sugar-raising, which made its prosperity. The English got possession in 1810. The area of the island is 705 square miles. Population 371,655. See works by J. G. Baker, G. Clark, and Keller's *Madagascar, Mauritius, and other East African Islands.*

Maury (*mâ'ri*), **Matthew F.,** an American naval officer and scientist, was born near Fredericksburg, Va., Jan. 14, 1806. In 1825, he entered the navy as midshipman on the *Brandywine*, then fitting out to take Lafayette to France. The next year his ship made a voyage to the Pacific, where he was transferred to the *Vincennes*, in which he sailed around the world. During this cruise and while still a passed-midshipman, he began his *Treatise on Navigation*, which was used as a text-book in the navy. After thirteen years' service he became lieutenant, in 1837, but two years later an accident lamed him for life and unfitted him for service afloat. In 1842, he was made superintendent of the hydrographical office at Washington, and two years later of the observatory. Here he made careful observations on winds and currents, from the results of which he wrote his *Physical Geography of the Sea*, and his works on the *Gulf Stream, Ocean Currents*, and on *Great-Circle Sailing*. Maury was made a commander in 1855, but when his state seceded he joined the Confederate navy. After the war, he was professor of physics in the Virginia Military institute at Lexington. He was a member of the scientific societies of Europe, and was practically the founder of the new and important science of hydrography. Professor Maury died at Lexington, Va., Feb. 1, 1873. See his *Life*, by his daughter.

Max'im, Sir Hiram S., American inventor, was born in Maine, Feb. 5, 1840, and became famous as the inventor of the automatic cannon known by his name. His first completed gun was exhibited in 1884. The principle of this gun was making the recoil of the weapon load and fire the weapon. He succeeded in making a gun that would fire six hundred shots a minute. The gun was first used in actual warfare by the British in Matabeleland. It was soon adopted by the French navy and now, under various names, is in use by all governments. He also invented a smokeless powder, incandescent lamps, and search-lights to be used on board men-of-war. He received a number of decorations from European courts. He was also made a member of many scientific associations. He has resided in England many years, and having transferred his citizenship to that country was knighted in 1901.

Maximilian (*maks-i-mil'yan*) **I.,** German emperor, the son of Frederick III., was born at Neustadt, near Vienna, March 22, 1459. When only nineteen he married Mary, the heiress of Charles the Bold, by which he gained Burgundy and Flanders. But this brought him into war with Louis XI. of France, the French kings having for many years cast longing eyes toward Flanders, and after the death of his wife, in 1482, Maximilian was forced to give Artois and Burgundy to Louis. In 1486, he was chosen king of the Romans. In 1490, he drove out the Hungarians, who, under Matthias Corvinus, had seized a great part of the Austrian territories on the Danube, and at Villach, in 1492, he routed the Turks. Artois and Franche-Comté were ceded to Maximilian by Charles VIII. of France, to prevent war between the two rivals for the hand of Anne of Brittany, who married Charles. The death of his father, in 1493, made Maximilian emperor. His marriage with the daughter of the duke of Milan turned his ambition toward Italy; but after many changes of fortune, he was driven to give up Milan to France and Verona to the Venetians. Nor was he more successful against the Swiss, who in 1499 freed themselves from German rule. He, however,

gained Tyrol by peaceful means; the houses of Spain and Hapsburg were joined by the marriage of their children, and the marriage of his grandson, Ferdinand, brought Hungary and Bohemia to Austria. Maximilian put an end to the feuds of his nobles, improved the courts, and divided the empire into six (afterward into ten) circles, each ruled by a governor. He also encouraged the universities of Vienna and Ingoldstadt, in learning and arts generally. He was well educated, skilled in all bodily exercises, chivalrous and genial; so that he has been called "the first knight of his age." Maximilian died emperor of the Holy Roman Empire, at Wels, in Upper Austria, Jan. 12, 1519. See Coxe's *History of the House of Austria.*

Maximilian (*măks-ĭ-mĭl'yan*), emperor of Mexico. Ferdinand Maximilian Joseph, archduke of Austria, was born July 6, 1832, at Vienna, and was the younger brother of Francis Joseph I. He became an admiral of the Austrian navy, and in 1857–59 he was popular as governor of the Lombardo-Venetian territory. In 1862, the French interfered in the affairs of Mexico, and the next year called together an assembly of notables, which offered the crown to Maximilian. After carefully reviewing the offer he accepted it, and in June, 1864, he entered Mexico. For a time all went well, but he was unable to keep the Mexican parties at peace. The republican leader, Juarez, again raised the standard of independence; and soon after (1866) Louis Napoleon was forced to think of withdrawing his troops. In vain the Empress Charlotte went to Europe to enlist aid for her husband; her reason gave way under the strain of excitement and grief brought on by disappointment. When the French withdrew, Maximilian felt bound in honor to stay and share the fate of his followers. At the head of 8,000 men he made a brave defense of Querétaro against a republican army under Escobedo. In May, 1867, he was betrayed and tried by court-martial, and on July 19 he was shot. His death was directly due to his own fatal edict of Oct. 3, 1865, that all Mexicans taken in arms against the empire should be shot without trial. See Kendall's *Mexico under Maximilian.*

Max-Muller (*mŭ'ler*), **Friedrich,** was born at Dessau, Germany, Dec. 6, 1823. His father, Wilhelm Müller, one of the greatest German lyric poets, died when Friedrich was four years old. He took his degree at Leipsicin 1843, and devoted himself to the study of Sanskrit. In 1847, the East India company commissioned him to edit the *Rig-Veda* at their expense. In 1854, he became professor of modern languages at Oxford. Max-Müller published treatises on many language topics, which have done more than the labors of any other single scholar to awaken in England a taste for the science of language, and by his happy illustrations has made attractive, subjects ordinarily dry. In 1875, he resigned his professorship and edited a series of translations of the *Sacred Books of the East.* Among his books are *Chips from a German Workshop, Comparative Mythology, The Science of Thought, Physical Religion, Selected Essays on Language, Mythology, and Religion, The Science of Language,* and *The Origin and Growth of Religion.* He died at Oxford, England, Oct. 28, 1900.

F. MAX-MÜLLER.

Max'well, James Clerk-, a very remarkable English physicist and one of the most brilliant and profound minds known to the history of physical science. He was born at Edinburgh, June 13, 1831, and there received his early training, first at the Edinburgh academy and afterward at the university. In 1850, he went to Cambridge university, from which he graduated, second wrangler, in 1854. From 1856 to 1860, he held the chair of physics in Marischal college, Aberdeen, and, for the next eight years, a corresponding position in King's college, London. Three years of retirement on his estate at Glenlair now intervene between his London residence and his acceptance of the newly created chair of experimental physics at Cambridge, where he lived and worked almost to the time of his death in 1879. Genius showed itself very early in his career; for, at the age of 15, a paper of his, on a mechanical method of drawing Cartesian ovals, was considered worthy of presentation to the Royal society of Edinburgh. His first great memoir was that which he offered in successful competition for the Adams prize in 1859. In this paper he proves, from purely dynamical grounds, that the rings of Saturn are made up of discrete particles, else these rings would not be stable. His investigations in the *Kinetic Theory of Gases* place him, with Bernoulli, Clausius, and Boltzmann, as one of the founders of that science. Towering above everything else, however, is his *Electromagnetic Theory.* His work began with a paper on *Faraday's Lines of Force,* which he later extended and perfected so that we have, in his *Treatise on Electricity and Magnetism,* a complete theory of the entire subject from Faraday's standpoint, that is, from the point of view which replaces all action at a distance by action through a medium. Ever since its publication, in 1873, this has been the standard treatment of electricity either in the English or in any other language.

As early as 1864, Maxwell predicted that electrical vibrations, if they could be produced, would have the same properties as light vibrations. It was not until 1888, nearly twenty years after Maxwell's death, that Hertz showed how to realize these electric oscillations in the laboratory and proved that Maxwell's equations had predicted the exact truth. These are precisely the electrical vibrations which Marconi and others have employed, since 1896, in wireless telegraphy. This discovery of Maxwell's may be stated more simply, perhaps, by saying that he showed that *optics* is merely one department of the subject of *electricity*.

His two small volumes, one on *Matter and Motion*, the other on the *Theory of Heat*, are marvels of elegance, conciseness, and clearness. They should be read by everyone who wishes to know the man. His collected *Scientific Papers* have recently been published by the *Cambridge Press*, in two superb quarto volumes.

Even this brief sketch of Maxwell would be incomplete without adding that, aside from his scientific attainments, his modesty, his genial humor, and his high Christian character endeared him to everyone who knew him. A more charming biography than the *Life of James Clerk-Maxwell*, by his friends Louis Campbell and William Garnett (London, 1884), would be difficult to find.

May, the fifth month of the year. The first of May has always been a gala day. The May festival goes back to the Floralia festival of the Romans, which probably came in the first place from India. The festival is still kept up by the Italians, under the name of "Calendi di Maggio"; young people sallying forth at daybreak to gather boughs with which to adorn the doors of relatives and friends. In England, as we learn from Chaucer and Shakespeare, it was customary during the middle ages for all, both high and low — even the court itself — to go out on the first May morning at an early hour "to fetch the flowers fresh." Hawthorn branches were also gathered, and were brought home about sunrise with blowing of horns and all possible signs of joy and merriment. The people then decorated the doors and windows with the spoils of spring. The hawthorn bloom was called the "May," the ceremony "the bringing home the May," and the trip to the woods "going a-Maying." The fairest maid of the village was crowned with flowers as the "Queen of the May," and placed in a little bower or arbor, where she sat in state, receiving the homage of the youthful revelers, who danced and sang about her.

Every town and village, too, had its fixed pole — called the Maypole — on which each May morning were hung wreaths of flowers, and round which the people danced in rings most of the day. A hard blow was given to Mayday by the Puritans, who had the Maypoles uprooted and a stop put to all these merry customs. They were, however, revived after the Restoration, but have now almost died out. In France and Germany, too, Maypoles were common, and in some places can still be seen. With Catholics the month of May is celebrated as the Virgin's month.

Mayence (*mā-yons'*) or **Mainz** (*mints*), the capital and largest town of the grand-duchy of Rhenish Hesse, Germany, on the river Rhine, near its union with the Main. It is a fortified city, with a double wall, bastions, and outworks, and a citadel in the center, and commands both sides of the Rhine. There is a monument to Gutenberg, with a statue by Thorwaldsen, and a bronze statue of Schiller in the public squares. The house in which Gutenberg was born is still standing, and also the one where he had his first printing press. Mayence is an old city, having been a place of importance under the Romans. Destroyed by the barbarians, in 406, it was rebuilt by the Frankish kings. It was the head of the league of Rhenish towns in the 13th century, and through Gutenberg became the bookmaking center. It was taken by the Swedes in 1631, by the French in 1644, and in 1688 by the Saxons, and Bavarians in 1689, and by the Prussians in 1793. In 1801, it belonged to France, but in 1816, was assigned to Hesse-Darmstadt. Since 1871 it has been a fortress of the German empire. Population 76,946.

May'nooth, a village in county Kildare, Ireland, fifteen miles northwest of Dublin. It is chiefly interesting from St. Patrick's Roman Catholic college, established in 1795 by an act of the Irish parliament for the education of the Irish priesthood. After the union of the two countries, the English parliament kept up the yearly endowment paid the college by the Irish parliament. The college received 500 students named by the Irish bishops. In 1869, a stated sum was given the trustees, and all connection with the government ceased. A new chapel was finished at a cost of $250,000 in 1890.

Mazarin (*mdz-a-rēn'*), **Jules**, cardinal and chief minister of France during the youth of Louis XIV., was born July 14, 1602, at Piscina, Italy. He studied under the Jesuits at Rome and at Alcala in Spain, and next entered the military service of the pope. His ability for diplomacy was early seen, and he accompanied a papal legate to the court of France. Here he met Richelieu, who foreseeing his future, engaged him to further French interests in Italy. In 1639, he openly entered the service of Louis XIII., was naturalized a Frenchman, and through Richelieu's influence gained a cardinal's hat. Richelieu further, before his death, recommended Mazarin to the king as his successor. He was a man of affairs, and had so much personal charm that he ruled with less friction than Richelieu, though with almost as great power. The

opposition of parliament to his taxes, followed by the arrest of the leaders, brought on the first of the wars of the Fronde. However, by the aid of Condé, the court triumphed, and though the hated taxes were abolished, Mazarin kept his office. The hatred against him, however, blazed out in the provinces, when he had Condé and Conti arrested in 1650. He had to go into exile, and the press teemed with pamphlets and satires against him — the famous Mazarinades. He now saw his mistake in separating himself and the queen from every party in the state, and bent all his masterly powers to form a new royal party. Turenne was gained over, and his military genius was more than a counterpoise to that of Condé, who was opposed to the court. In 1653, Mazarin came back in triumph to Paris, and from this time his power was re-established, while he quickly regained his popularity. Under his rule, the influence of France abroad was greatly increased. He gained the alliance of Cromwell by giving up Dunkirk; made French influence felt in southern Germany by the treaty of Westphalia in 1648; while the league of the Rhine, formed in 1659, and in the same year the marriage of Louis XIV. with the infanta Maria Theresa, made France a claimant of the throne of Spain. Mazarin died at Vincennes, France, March 9, 1661. See Gustave Masson's *Mazarin*.

Mazeppa (*mȧ-zep'ȧ*), **Ivan Stephanovich,** hetman or chief of the Cossacks, was born in 1664, of a poor but noble family of Podolia, Poland. He became a page at the court of John Casimir, king of Poland. A jealous nobleman had him stripped naked, and bound on his own horse, lying on his back and with his head to its tail and let the animal loose, leaving Mazeppa to his fate. The horse carried him, senseless from exhaustion, to its native wilds of the Ukraine, according to the usual story. A more likely account is that his horse carried him through woods and thickets and brought him back, torn and bleeding, to his own home. Mazeppa now joined the Cossacks, became secretary to their hetman, Samoilovich, and in 1687 was chosen his successor. . He won the confidence of Peter the Great, who loaded him with honors, and made him prince of the Ukraine. But when Russia interfered with the freedom of the Cossacks, Mazeppa determined to free them from the rule of the czar, and to this end conspired with Charles XII. of Sweden. Peter the Great discovered the treason, but for a long time refused to believe it. Mazeppa's hopes perished in the disastrous battle of Pultowa, in 1709, and with Charles he fled to Bender, the Russian fortress in Bessarabia, where he died the same year. His story is the subject of a famous poem by Byron, and of two paintings by Vernet.

Mazzini (*mȧt-sē'nē*), **Giuseppe,** Italian patriot, born at Genoa, June 22, 1805. He went to the University of Genoa when only thirteen, and before he was nineteen was a practicing lawyer. In 1821, the sight of the refugees from the unsuccessful rising in Piedmont stirred him to devote himself to freeing his country. As a member of the Carbonari he was arrested and imprisoned in 1830. When set free the next year, his life-plan was settled. His first step was the formation at Marseilles of the Young Italy association. The first and last duties of its members was to work to make a free, independent, and united nation of Italians. The great mass of the people were to be educated to understand their rights, and taught to secure them, if need be, by force. Shortly after Charles Albert became king of Sardinia, Mazzini urged him to put himself at the head of the struggle for national independence. His answer was a sentence of banishment, and soon the French expelled him too, but he managed to hide in Marseilles. From this time he led "a life of voluntary imprisonment within the four walls of a little room" for over twenty years. During this time he was the most untiring political agitator in Europe, the man most dreaded by its absolute governments. He was always writing, and so eloquently and sincerely, that he aroused his followers to an enthusiasm that would dare anything. In 1834, he organized an invasion, which failed, chiefly because of the lukewarmness or treachery of the soldiers to whom it was intrusted. From his headquarters, in Switzerland, his organization was extended throughout Italy. Banished from Switzerland he went to England, where for seven years he struggled hard against poverty, yet managed to help his poorer, ignorant countrymen, the London hand-organ boys, by teaching and civilizing them in night-classes. In 1844, the English government was forced by a storm of indignation, in which Carlyle took a leading part, to apologize for opening Mazzini's letters and sending their contents to the rulers in Italy.

On the outbreak of the Lombard revolt, in 1848, Mazzini threw himself into the heart of the struggle, though the king of Sardinia sought to win him over by the offer to make him the first minister of the new Piedmontese-Lombard state. When the revolt in Lombardy failed, he made his way to Tuscany. Leghorn received him with wild enthusiasm in February, 1849, the day before the republic was proclaimed at Rome, and elected him her deputy to the republican assembly in the papal city. On March 29, Mazzini was chosen one of three triumvirs with the powers of dictators. They chose as their motto, "God and the People." But on April 25 the French arrived before Rome and after a hard struggle the republic fell. Mazzini made his way back to London, where he planned the risings of the following years at Mantua, Milan, Genoa, and Leghorn. He was sentenced to death three times, but died peace-

fully at Pisa, Italy, March 10, 1872. Italian nationality is chiefly due to three men, Mazzini, Garibaldi, and Cavour. Perhaps it is safe to say that Mazzini prepared the soil, sowed the seed, and fostered the growing plants that Garibaldi gathered in the ripe fruit; but it was Cavour who gained the final advantage of the harvest. See Marriott's *Makers of Modern Italy*.

Mead, Larkin Goldsmith, an American sculptor, was born at Chesterfield, N. H., Jan. 3, 1835. His early years were spent in Vermont. He studied art at Brooklyn, N. Y., and in Italy. The *Recording Angel*, his first work, was modeled in snow and afterward cut in marble. His large pieces have been executed for public buildings and monuments; such as the colossal statue of *Vermont*, on the dome of the statehouse, and of *Ethan Allen* in the portico of the same building in Vermont, and one of the same hero, given by the state of Vermont to the hall of representatives at Washington. The statue of Lincoln on the monument at Springfield, and a group representing *Columbus before Queen Isabella*, for the state of California, the *Returned Soldier*, and the *Return of Proserpina from the Realms of Pluto*, which was over the main entrance of the Agricultural building at the World's Columbian exposition, Chicago, are other specimens of his larger statues.

Meade, George Gordon, an American general, born at Cadiz, Spain, Dec. 31, 1815. In the Mexican war he was on the staff of General Taylor, and afterward of General Scott, and won honor at the battles of Palo Alto and Monterey. From 1856 to 1861, he was in charge of the surveys of the Great Lakes. In the Civil war, he was in command first of the Pennsylvania brigade, and fought in the battles of Gaines' Mill and Frazier's Farm, where he was severely wounded; at South Mountain, Antietam, and Fredericksburg. He was in command of different corps of the army of the Potomac. Meade succeeded Hooker in the command of the army of the Potomac, and fought the battle of Gettysburg, July 1–3, 1863, receiving in 1866 the thanks of Congress for "his skill and heroic valor." He was made major-general in the regular army in 1864, and retained the command of the army of the Potomac, under General Grant, during the battles of the Wilderness, the siege of Petersburg, etc., until the close of the war. He was in command of the division of the Atlantic, 1865–66; of the department of the east, 1866–67; and later of the military district, which included Georgia, Alabama, and Florida. His headquarters were at Philadelphia, where he died, Nov. 6, 1872, at his home, the gift of his grateful fellow-citizens. See GETTYSBURG.

GEN. G. G. MEADE.

Meadow Lark (*mĕd'ō lark*), a bird belonging to the family of American Orioles. It lives in meadows, but is not a lark. It is essentially a ground bird, feeding on the ground, and making its nest in a tuft of grass. The bird is black, brown, and buff above, and yellow below, with a black crescent crossing the breast. They are sweet singers, and usually when singing seek a high and exposed perch. They feed on larvæ, worms, beetles, grass seed, etc. In autumn they collect in small flocks of ten or twelve and visit marshes and stubble fields.

Mead'ville, Pa., capital of Crawford county, on the Venango river, in northwestern Pennsylvania, 125 miles north of Pittsburg. It is on the Erie railroad, and in railroad connection with Pittsburg and Lake Erie. It is the seat of a number of educational institutions, schools, colleges, conservatories of music, and half a dozen libraries. Here is Allegheny college, a Methodist Episcopal institution, with some 20 instructors and 350 students; also a Unitarian Theological college. Its industries include manufactures of engines, boilers, leather-belting, oil-well supplies, wood mantels, sashes, and blinds. The city has good water-works, natural gas for fuel and lighting, electric-light plants, etc. Population 10,291.

Meas'urement consists essentially in the comparison of one quantity with another. Thus the measurement of a length, which is one of the simplest of all measurements, consists in determining how many times greater or less the given length is than some other given length which we agree to take as a unit. In like manner, an interval of time is "measured" by comparing it with the interval which we employ as a unit, namely, the mean solar day. Evidently, therefore, it is possible to measure a quantity without understanding very much about that quantity. No intelligent measurement, however, can be made unless one understands just what quantities are necessary to define the quantity about to be measured. Thus the position of a point in space is intelligently measured only when we know that three definite and independent co-ordinates are required to locate the point, and when we have determined the numerical values of these three co-ordinates. To measure the kinetic energy of a body in translation we must know how many units of mass there are in the body and with how many units of speed it is moving. Thus also we may measure accurately and definitely the acceleration of gravity at various points

on the earth's surface, and yet not know the explanation of gravitation.

It has been found that practically all the quantities involved in physical science and engineering can be measured in terms of three quantities, viz., a *length*, a *time*, and a *mass*. The units of these three quantities are, therefore, called the *fundamental* units.

The standard of length, except in English and American commerce, is the *metre;* the standard of time the *mean solar day;* and the standard of mass is the *kilogramme*. (See KILOGRAMME, EARTH, and METER.) Units are founded upon standards, but they are often different in size from standards, and may be chosen of a size which, for any particular purpose, is most convenient. Thus, in physics the centimetre, or $\frac{1}{100}$ of a metre, is most frequently employed; and in astronomy the second ($\frac{1}{86400}$ of a day) is frequently a very convenient unit of time, while often the year (or 365 days roughly speaking) is more convenient.

It is a well-established principle that no physical measurements can be carried out with absolute accuracy. Every comparison is affected with error to some extent. Even the standard meter at Paris, which is correct by definition, may be changing its length owing to crystallization. The rate of rotation of the earth is probably diminishing (and hence the length of the mean solar day increasing) owing to tidal friction. So that, even if comparisons could be made with perfect accuracy, the final measurement would still be affected with error. On the other hand, the precision of modern measurement almost surpasses belief. Michelson, for instance, has succeeded in making a comparison of the standard metre with a wave-length of cadmium light in which the error does not exceed about one part in two millions. Two masses may be compared with even greater accuracy. See Everett's *Units and Physical Constants*.

Mecca (*mek'ă*), the holy city of the Moslems, is one of the oldest cities and the capital of Arabia. It is built in a narrow valley, surrounded by hills, which are crossed by two passes. The place is so secluded that the city is only seen when the traveler comes close upon it. It commands the principal caravan routes, and so became early a center of trade. The city is mainly modern, as the ancient buildings have been mostly destroyed by mountain torrents. The streets, unpaved and dirty, are broad, while the houses of stone, three and four stories high, climb the mountain sides. There is no drainage, and provisions of all kinds have to be brought into the city, owing to the barrenness of the soil. The population numbers about 60,000, who live upon the pilgrims who flock to the city, and upon the manufacture of sacred relics. What gave Mecca its first reputation as a holy city is uncertain, though it is probably the possession of the Black Stone, or fetish of the Kaaba, which attracted pilgrims ages before the time of Mohammed. This Black Stone is a small meteoric substance, and is built into the southeast corner on the outside of the temple, or Kaaba. There is another sacred stone, called the Southern Stone. The Moslems changed the idol temple with its heathen fetish, to a temple built by Abraham when he cast out Ishmael. The temple of Mecca, or the Great Mosque, is an open court surrounding the Kaaba, and has nineteen gates, with seven minarets, and holds 35,000 persons. The pilgrims walk around the Kaaba seven times, kiss the Black Stone, and touch the Southern Stone, and pass around a small inclosure containing the supposed graves of Hagar and Ishmael. The Kaaba is covered with rich hangings, presented by the Sultan of Turkey; has a door of silver and gilt, which is seldom opened to display the rich silver, marble, and silk decorations of the interior. It is about 70 feet long, about 50 feet wide, and nearly 40 feet in height. Every Mohammedan, whose means or health will permit, is obliged to make the pilgrimage to Mecca at least once. The Arabic word for a pilgrimage is hadj—and hence the Mohammedan who has made the journey to Mecca is called afterward a hadji or hadjji. Some who cannot make the journey themselves send some one in their place, but the honor and rewards of the deed do not belong to the substitute, but to his employer. The sacred well of Mecca may once have been a mineral spring, but its analysis now gives sewage matter as its principal element. The city was conquered by Mohammed in 627, five years after he had fled from it. The Carmathians sacked it in 930, carrying off the Black Stone and keeping it for twenty-two years. It belongs now to the Turkish empire (it passed to the Turks in 1517), though the real governor is the sherif or the reputed head of the descendants of Mohammed. See Burkhardt's *Travels in Arabia; Mahomet*, by Washington Irving.

Mechanics (*me-kăn'iks*) is a word employed with two distinct meanings. Sometimes it is used to denote the science of Matter and Energy, more properly called *Dynamics;* and sometimes it is employed to denote the application of dynamical principles to the theory of structures and to the theory of machines. Used in this latter sense, it is a branch of engineering and might more properly be called *Applied Mechanics*. At other times, Mechanics is used in a mixed sense to include both a discussion of Dynamics and the application of dynamical principles to structures and machines.

For a treatment of *pure* mechanics the reader is referred to DYNAMICS. For applied mechanics see BRIDGE, STEAM ENGINE, PUMP, LEVER, PULLEY, etc.

On pure mechanics — dynamics — see Minchin's *Treatise on Statics*, Tait and Steele's *Dynamics of a Particle*, and Thomson and Tait's *Treatise on Natural Philosophy*. Slate's *Mechanics* gives an excellent elementary résumé of the subject. Worthington's *Dynamics of Rotation* is still more elementary. For the applications of mechanics see Church's *Mechanics of Engineering*, Johnson's *Materials of Construction;* and Ewing's *Strength of Materials*. For the history of the subject, see Mach's *Science of Mechanics*, or Whewell's *History of the Inductive Sciences*.

Mechlin (*mek'lin*) or **Malines**, a city of Belgium, thirteen miles northeast of Brussels. It is a railroad center, and has manufactories of woolen, linen, lace, and beer. The Mechlin lace, so well known, is made here, but the trade is much less than formerly, and the quality of the lace now made is below the former standard. It is a picturesque city, with fine public buildings, among which are the cathedral, several large churches, the bishop's palace, widows' asylum, and the college. In the public square, or Grande Place, is a statue of Margaret of Austria, and some paintings of Rubens and Vandyke are to be found in the churches. Population 55,530.

Medes (*mēdz*), the people of Media, the ancient name for northwestern Persia. The inhabitants, called Medes, were an Aryan race. They were followers of Zoroaster, and their priests were the Magi. They were bold and warlike, skillful in the use of the bow, and noted horsemen. They were partly subject to Assyria until about 700 B. C., when they had a chief, with his capital at Ecbatana, now Hamadan. With the aid of the conquered Persians, and the king of Babylon, Cyaxares, the third king, or, according to some authorities the first, captured Nineveh, and overthrew the Assyrian empire, about 607 B. C. An eclipse, foretold by Thales, May 28, 585 B. C., stopped the career of conquest by frightening both parties into peace. In 550 B. C., the Persians under Cyrus revolted, and overthrew the Median king, Astyages, and the two nations became one people, and are spoken of as the Medes and Persians. Ecbatana was made the summer residence of the kings of Persia. The kingdom was divided after the death of Alexander the Great, the northwestern part, called Media, being a separate province, while the rest of the country, known as Great Media, belonged to Syria. Mithridates I. took Great Media in 147 B. C. from Syria and attached it to Parthia. Mark Antony fought a disastrous campaign against it about 36 B. C., when it seems to have had a king of its own. Media was finally again united with Persia, and her later history is that of Persia. See *Five Great Monarchies of the Ancient Eastern World*, by Rawlinson; *Races of The Old Testament*, by Sayce; and *Media, Babylon, and Persia*, by Miss Ragozin, in *Stories of the Nations*.

Med'ford, Mass., an old city of Middlesex county, on the Mystic river, and the Boston and Maine railroad, five miles northwest of Boston. It is also connected with Boston by electric railway. Here is the seat of Tufts college, belonging to the Universalist denomination. Its manufactures embrace felt boots, pressed and face brick, and print and dye works, paper mills, carriage factories, and brass foundries. It also manufactures crackers and rum. The city dates from 1630, but was organized as a city only in 1892. Population 18,244.

Medici (*med' ē-chē*), a celebrated Italian family in Florence and Tuscany, who attained sovereign power in the 15th century, and were great patrons of art and letters, as well as noted statesmen.

Med'ici, Lorenzo de, the Magnificent, was born of a wealthy Florentine family Jan. 1, 1448. He was highly educated and early showed his great abilities. On the death of his father, Pietro I., Lorenzo with his brother, Giuliano, were recognized as rulers. The great power of the Medici roused the envy of other Florentine families, and in 1478 they, in league with the pope, Sixtus IV., plotted to overthrow them. Giuliano became the victim of the assassin, but Lorenzo defended himself with such courage and vigor and diplomacy as finally to put down the conspiracy, in spite of the papal bull and the aid of the king of Naples. Innocent VIII., the successor of Sixtus IV., became the friend of the Medici family, and opened to them many of the positions of power which they filled. Lorenzo was a patron of art and literature, and himself a distinguished poet. He established a printing press at Florence and the University of Pisa, and enlarged the library founded by his grandfather, Corimo. He governed the state well, but made everything yield to the advancement of his family, and so left Florence weakened and ready to be the prey of her enemies. He died April 8, 1492. See *Life* by Roscoe; *Poetry and Poets of Europe*, by Longfellow; *Lives of Italian Poets*, by Stebbing.

Medi'na, Arabic for "the city," is, next to Mecca, the holiest city of the Mohammedans, because it was the home of Mohammed after his flight from Mecca. It is situated in western Arabia, about 270 miles north of Mecca. About half as large as Mecca, it is inclosed by a wall from 35 to 40 feet in height, with thirty towers, and a castle with a Turkish garrison, making it one of the strongest fortified places in that part of Arabia. The present population, of about 46,000, live by agriculture, and the alms or spoils of the pilgrims, who flock there as to Mecca, but at no particular time. The prophet's mosque is thought to be built on the spot where Mohammed died, and to

surround his tomb. It is smaller than the temple at Mecca, and has been rebuilt several times. The sepulchre, in the southeast corner, is an irregular chamber, from 50 to 55 feet in height, with a large gilt crescent above. Within, costly curtains, embroidered with gilt letters, cover a square building of black marble, where the prophet's body is believed to lie undecayed, with the face toward Mecca. No European has ever been allowed to see the coffin, which is cased with silver, and covered with a marble slab; but there seems no reason to doubt that it is really the burial-place of Mohammed. The city was once famed for its scholars and theologians, and in the 7th century, was the capital of Islam.

Med'iterra'nean Sea is the largest inclosed sea in the world. It is connected with the open ocean (the Atlantic) only by the narrow strait of Gibraltar, nine miles wide. The name is derived owing to its being in the midst of the three continents, Europe, Asia, and Africa. It is 2,200 miles long, varies from 500 to 100 miles in width, and has an area of 900,000 square miles. It is connected with *the Black* sea by the Dardanelles, sea of Marmora, and the Bosphorus. The coasts of *Europe* and Asia Minor have many bays and gulfs, while the coast of Africa is even, with few indentations. The Tyrrhenian, Ionian, Iberian, Ægean seas, and the Levant are names by which the different parts of the Mediterranean have been known. Sardinia, Corsica, Sicily, Malta, Cyprus, and Crete are among the larger islands. The region is subject to earthquakes, and Vesuvius, Stromboli, and Ætna are its most famous volcanoes. The bottom of the sea is divided into two parts by a ridge which crosses it from Sicily to Africa, the water being deepest in the eastern basin. The evaporation from the surface is greater than the amount of water poured into it by the rivers flowing into it, and if it were not for the water of the Atlantic ocean, which flows in at the strait of Gibraltar, above the outflow of the heavier water of the Mediterranean, the sea would become salter and shrink into two salt lakes, like the Dead sea. There are also two currents at the entrance of the Black sea, as of the Atlantic, an inflow of fresh water from the Black sea, and an outflow of salt water from the Mediterranean. The Suez canal now connects the Mediterranean with the Red sea. The chief rivers that flow into it are the Rhône, the Po, and the Nile. The countries bordering the Mediterranean, Phœnecia, Greece, and Italy, have been the cradle of civilization, and the sea is well known in history and poetry and ancient story, and is to-day one of the most important water routes of the world.

Medulla Oblongata (*mē-dŭl'lo ŏb-lon-gä'ta*), the part of the hind-brain merging into the spinal cord, the hind-brain being made up of the cerebellum and the medulla oblongata. It is a very important part of the brain. The cranial nerves, with the exception of the optic and olfactory nerves, are connected with it, and in it are also located clusters of nerve cells — or especial centers — that preside over special actions. Here are located, for example, the respiratory center, controlling the respiratory movements; the cardiac center, for regulating the action of the heart; the vaso-motor center, for regulating the calibre of the blood vessels; the sneezing center and others. These centers may be excited to greater activity or held in check (inhibited) by various forms of stimulation from the external world or from within the body. See BRAIN.

Medusa (*me-dō'sä*), in Greek mythology, one of three sisters called the Gorgons. They had but one eye among them, a fortunate circumstance, as whoever they looked on was changed to stone. Medusa is represented in art as a winged virgin, with hissing snakes for hair, brazen claws, and a single tusk for a tooth. They kept the garden of the Hesperides, where Medusa was slain by Perseus.

Medusæ (*mē-dō'sē*), a group of free swimming jellyfish. They have a dome-shaped or umbrella-shaped swimming disc of jelly-like consistency. From the margin of the disc hang many tentacles, which, from their fancied resemblance to the snaky locks of Medusa, the gorgon, gave these animals their name. In many cases the medusæ are modified polyps, set free from branching colonies of hydroids. Those derived in this way are called medusoids, and they carry the reproductive elements of the forms from which they are set free. In this variety, the opening into the swimming bell is partially closed by a circular membrane, and they are called crespadote medusæ. Other medusæ have usually a larger and more flattened disc and lack the membrane (acrespadote). They have also certain other technical peculiarities. See CŒLENTERATA, HYDROZOA, and JELLYFISH.

Meerschaum (*mēr'shawm*), is a mineral, found in several parts of the world, consisting of hydrous magnesium silicate. It is a white clay-like substance, which, when dry, will float on water: hence its name, which means sea-foam. When first dug from the earth it is soft, like soap, makes a lather in water, and takes out grease, and is often used instead of soap by the Turks. In Europe, it is found in Moravia, Spain, and the Crimea, and in Turkey in Asia there are large beds of it just below the soil. It is also found in South Carolina. Its use is almost entirely for the manufacture of tobacco pipes, the Austrians being most largely engaged in the trade. The pipes made at Vienna are often worth $500, from the great beauty of their design. The waste material left after cutting the pipes is ground into powder, and mixed into a paste, from which the cheaper pipes are made.

Megaphone (*mĕg'a-fōn*), a large funnel-shaped tube used for reflecting sound. A tube of this kind may be used either to receive sound, when it becomes an "ear trumpet," or it may be used to transmit sound, in which case it becomes a "speaking trumpet." The principle of the megaphone is exactly the same as that employed in the headlight of a locomotive, where the light waves are reflected and sent out in a more or less parallel beam along the track. The only difference is that, in the megaphone, sound waves, and not light waves, are reflected.

The two principal uses of the megaphone at present are, *first*, to transmit the sound of a phonograph in the direction desired, and *second*, to transmit the human voice to a long distance, or to a large audience, as at horse-races and ball games.

Megasporangium (*mĕg'a-spō-răn'jĭ-ŭm*) (in plants), the sporangium which produces megaspores. In pteridophytes (fern-plants), they are produced by the water-ferns, selaginella and isoetes; while in all seed-plants (spermatophytes) the so-called "ovules" are megasporangia, sometimes called "macrosporangium." See HETEROSPORY.

Megaspore (*mĕg'a-spōre*) (in plants). In cases of heterospory (which see), the large asexual spores are called "megaspores," sometimes "macrospores." In germination a megaspore produces a female gametophyte, that is, one which bears the eggs. Megaspores are found in a few pteridophytes, and in all spermatophytes. In the latter group but a single megaspore is produced by the megasporangium (ovule), and is not shed, often being called the "embryo-sac." It is this single retained megaspore which results in the formation of a seed by the ovule. See HETEROSPORY.

Megasporophyll (*mĕg'a-spōr'ō-fĭl*) (in plants), the sporophyll which bears megasporangia, sometimes called "macrosporophyll." Megasporophylls are chiefly developed in seed-plants, and in the angiosperms (true flowering plants); they have been called "carpels," the innermost organs of flowers. See HETEROSPORY.

Meissonier (*mā'sō'nē-ā'*), **Jean Louis Ernest**, a French artist, was born at Lyons, Feb. 21, 1815, in great poverty. As a youth he painted several early pieces which he sold at one dollar the square yard. When nineteen years of age he succeeded in getting to Paris, where he was soon admitted to the studio of Leon Cogniet, by whom his ability was soon recognized. His distinctive excellence in small paintings finished with exquisite precision was soon developed, and many of his most celebrated pieces are but a few inches in height or breadth. His first public exhibition occurred in 1834. From that time he was popular and prosperous. In 1843, he won his earliest first-class medal, and in 1846 he received the decoration of the Legion of Honor. In 1861, he became a member of the Institute. No one has excelled, few have ever approached, him, in his chosen field. Nearly all of his pieces have to do with the military, and his masterpiece, *Friedland — 1807*, one of the largest, by the way, he ever painted, was brought to New York and is now in the Metropolitan museum of that city. He died at Paris, Jan. 31, 1891. See *Life*, by Mollet.

Melanchthon (*me-lank'thon*), **Philip**, a German reformer and friend of Luther, was born Feb. 16, 1497, at Bretten, in Baden, Germany. Melanchthon is the Greek form of his German name, Schwarzerd. He studied at Heidelberg and Tübingen. He lectured on the philosophy of Aristotle in 1514, and soon after published a Greek grammar. His appointment to a Greek professorship at Wittenberg in 1518 brought him into contact with Luther. He threw himself at once into the work of the Reformation, bringing to it an extent of learning nearly equal to that of Erasmus, and a gift of clear thinking and expression unequaled among his fellow workers. His influence was in favor of peace and moderation, which, although he carried it to such an extent as to lose in some degree the confidence of the Protestant party, did much to preserve the reformation from excesses which would have hindered its progress. The first great Protestant work on theology was written by him and published in 1521, going through more than fifty editions in his lifetime. In 1530, he published his defense of what is known as the Augsburg confession of faith, the foundation of the Protestant religion in Germany, which confession had been prepared by him and submitted to the assembly of German princes at Augsburg. Melanchthon's works are very numerous, including commentaries on parts of the Bible and classical works, books of doctrine and moral philosophy, and a large correspondence with the leading men of the age. He ranks among the highest names in the history of learning and education. He died at Wittenberg, April 19, 1560. See *Life*, by Cox; *History of the Reformation*, by D'Aubigne.

Melbourne (*mel'burn*), the most important city of Australia, the capital of the colony of Victoria, is situated at the northern end of Port Philip bay on both sides of the river Yarra. Its streets are wide, crossing each other at right angles, with a great many fine buildings. It is the center of the railroads of Victoria, and has numerous factories, foundries, and flour-mills. Its university, with three colleges, and a workingmen's college, are the principal educational institutions. The exhibition building, post office, law courts, the houses of parliament, costing $5,000,000, the royal mint, custom-house, and the treasury are among the fine public edifices. The growth of Melbourne has been very rapid. It was

first occupied by white men in 1835. In 1851, at the time of the discovery of gold in Victoria, it had a population of 25,000. In 1899, it numbered 480,000, including the suburbs. In 1888, an international exhibition was held on the hundredth anniversary of the settlement of Australia, which cost the colony $1,000,000. Melbourne was, in 1901, visited by the duke of Cornwall (heir apparent to the English crown), and his consort, on the occasion of the opening of the first parliament of Federated Australia. See *Victoria and its Metropolis*, by Lord Melbourne.

Melchizedek (*mel-kĭz'ē-dĕk*) ("king of righteousness"), a Bible character called king of Salem and priest. Salem is thought to be a poetical name for Jerusalem. According to the story in Genesis, this king met Abraham on his return from a victorious expedition, and blessed him, and Abraham gave him a tenth of the spoils he had taken. There are two other allusions to him in the Bible, one in Psalms cx., where his priesthood is referred to, and again in Hebrews vi. and vii., where he is used as a type of Christ.

Melegnano (*mā-lĕn-yä'nō*), formerly called Marignano, a town of Italy, on the Lambro, nine miles south of Milan. It is noted as the scene of a battle between France and the Swiss troops under the duke of Milan, in 1515, where Francis I. was the victor. It was called the "battle of the giants." In June, 1859, a French force routed the rearguard of the Austrian army at the same place. Population 5,438.

Melo'deon, a musical instrument somewhat like a piano in appearance, but depending upon a bellows and reeds for producing the musical sounds. It was manufactured in the United States, over 20,000 being made in 1859, but is now superseded by the cabinet organ, which is somewhat like the melodeon, with many and great improvements.

Mel'on, the general name most commonly associated with muskmelons and watermelons, and sometimes extended to include gourd fruits in general. See MUSKMELON, and WATERMELON.

Mel'rose Ab'bey, a celebrated abbey in Roxburghshire, Scotland, situated near the town of Melrose, on the river Tweed, 30 miles from Edinburgh. It was built in 1136 by David I. of Scotland, was twice burned by the English, rebuilt in greater splendor, only to be again destroyed by English invasions. It is, even in ruins, one of the finest examples of Gothic architecture, and in its prime was the most beautiful building in Scotland. The abbey has been made celebrated by the writings of Sir Walter Scott, whose seat, Abbotsford, is in the vicinity, and is visited by many tourists. See *The Abbot*, and *Lay of the Last Minstrel*, by Scott.

Mel'rose, Mass., a city of Middlesex county, eight miles north of Boston, on the Boston & Maine railroad. It is a growing town and possesses a number of schools, churches, public parks, halls, and library, together with several banks, hotels, and club-houses. Its industries include the manufacture of boots and shoes, furniture, silver polish, sewing-machine needles, etc. Population 12,962.

Mel'ville, George W., an American engineer, was born at New York, Jan. 10, 1841. He was educated at the Brooklyn Polytechnic, and entered the United States navy July 29, 1861, as third assistant engineer. He became engineer-in-chief of the navy in 1887, and rear-admiral in 1899. He personally contributed not a little to the building up of the new American navy by various inventions. During his term 120 ships with a combined force of 700,000 horse power were constructed under his supervision. In 1879 he joined the Arctic expedition under command of Lieutenant DeLong, and commanded the boat's crew which escaped from the delta of the Lena. He afterward recovered the records of the expedition and recovered also the remains of the unfortunate party which perished on the shores of Siberia. He received a gold medal by special act of congress for his bravery and success in this.

Mem'non, one of the heroes of the Trojan war, was, in Greek mythology, the son of Aurora. He led a band of Ethiopians to the aid of Troy, slew Antilochus in single combat, and was himself slain by Achilles. Two famous statues were discovered by the Greeks at Thebes, and one of them was supposed to be that of Memnon, though more probably that of an Egyptian king. It is one of the "seven wonders of the world," is about 60 feet high, and gave out a sound like the snapping of a chord, about sunrise. The Greeks called it "the voice of Memnon hailing his mother, Aurora" (the dawn). It was visited by many travelers until the time of the Emperor Severus, when it became silent, and it is inscribed with the names of many celebrated

visitors. The origin of the sound is a matter of conjecture, though it has had several explanations. See *Edinburgh Review*, July, 1886.

Mem'phis (*mem'fis*), the well-known city of Egypt, was the ancient capital of the country. It is situated on the Nile, ten miles south of Cairo. The city was founded by the first Egyptian king, who changed the bed of the Nile, and built an embankment to protect the new city, the remains of which are still to be found. It was a large city, about seventeen miles in circuit, according to some writers, having communication with both the Mediterranean and the Red sea. It had a large trade, and was the seat of learning and religion. It was the capital of Egypt for nearly a thousand years. It was conquered by Sennacherib and by the Persians; Alexander the Great worshiped at the shrine of the sacred bull, and the first Ptolemies were crowned in its temples. Ptolemy VIII. destroyed the city, and it fell with the rest of Egypt under the Roman power. Its temples were magnificent, including the temple of Isis, the temple of the Apis, that of Ptah, where was kept the sacred bull, and that of Serapis, where was a nilometer to record the floods of the Nile. Most remarkable of all the ruins of Memphis are the pyramids, including the great pyramid of Cheops and the statue of the Sphinx. Memphis remained the chief city of Egypt until Alexandria was built, when it fell into ruins, and for a long time even its site was unknown. The village of Mitrahenny now marks the spot, and the ruins of temples and palaces and statues cover hundreds of acres. See *Story of Ancient Egypt*, by Rawlinson; *Egypt from 4400 B. C.*, by Clement.

Mem'phis, a city of Tennessee, in Shelby county, is built on a bluff, 35 feet above high water, on the Mississippi river. Its river and railroad communications bring it a very large trade. It is one of the largest cotton markets in the country, and has numerous foundries and machine shops, and some of the largest oil mills in the United States, producing over $1,000,000 worth of cotton-seed oil a year. It has a large lumber trade, with 1,000 lumber mills in the region. It is a handsome city, with many fine public buildings, including a custom-house, cotton exchange, Roman Catholic college, large hospitals, and theatres. An epidemic of yellow fever in 1878 and 1879 destroyed nearly 10,000 inhabitants; since then a new system of drainage has been introduced, making it one of the healthiest cities of the country. Population 102,320.

Memphremagog (*mem-fre-ma'gog*), **Lake,** on the northern border of Vermont, adjoining the Canadian province of Quebec, is about 35 miles long and from two to five miles wide. It has many islands and an abundant supply of fish. Owl's Head and Sugar Loaf are mountains on the western shore, and the whole region is very picturesque.

Menai Strait (*men'i* or *men'ā*), a channel separating the island of Anglesea from Wales. It is 14 miles long and from 200 yards to two miles wide. The navigation is difficult, but the passage is much used, as it saves time. The channel is crossed by a suspension bridge, built in 1825, and by the famous Britannia bridge, built in 1850. This is a tubular iron bridge, used for railroads.

Mendelssohn-Bartholdy, Felix, the composer, was born at Hamburg, Germany, Feb. 3, 1809. The name was already famous through his grandfather, Moses Mendelssohn, the philosopher, but his father determined to bring up his children as Christians, and added Bartholdy to the name to distinguish them from the Jewish branch of the family. At eight years of age, Mendelssohn studied music, and two years later appeared in a concert in Berlin. In 1820, when only eleven years old, he began his work of musical composition, which ended only with his death. He made the acquaintance of all the great men of his day, such as Goethe, Weber, and Moscheles. His operas, *Camancho's Wedding*, and *Midsummer Night's Dream*, were published in 1825 and 1826; and in 1827 the first one was produced in Berlin. Though received with great applause, it was never repeated, and was severely criticised. He formed a choir for the study of Bach's Passion music, ending a famous performance in 1829. He visited England in April, 1829, making his first appearance in a concert of the Philharmonic society at London. He visited Munich, Vienna, Rome, and Paris before returning to Berlin. He spent two years at Dusseldorf, having charge of some musical and dramatical entertainments. Leipsic became his home in 1835, where he took charge of the Gewandhaus concerts, visiting England in 1837 and again in 1840, and Berlin for a year in 1841, at the command of the king. In England, he conducted his *St. Paul*, which was very popular, and in Berlin he composed the music of *Antigone* and *Œdipus*. His oratorio, *Elijah*, on which he spent nine years, was composed for the Birmingham festival and was brought out there in 1846. He was eminent not only as a composer, the list of his works being very large, but as a pianist and organist. He had also a gift for drawing and improvisation. He was always a great favorite with English audiences, his *Elijah* having retained its popularity for forty years. But his excessive labors brought on a brain trouble from which he died, Nov. 4, 1847, at his home at Leipsic. See *Letters; Life*, by Moscheles and Lampadius.

Mendez Pinto (*men'dēz pēn'to*), **Fernao,** was a Portuguese adventurer, born about 1510. He began his adventures by going as a volunteer against the Turks in the Indian ocean, and the Red sea, about 1537. In twenty-one years of service, shipwreck, and

encounters with pirates, he was thirteen times captured and seventeen times sold as a slave. He first saw Japan while in the service of a Chinese pirate, and on returning to Ningpo his stories of its wealth induced the Portuguese living there to fit out nine ships in fifteen days to visit the new country. The vessels were lost, however, and Pinto found his way back to China. He made three other visits to Japan, once in company with St. Francis Xavier, and once as ambassador from the Portuguese viceroy of India. His fortune, which was enormous, he devoted almost entirely to founding a Roman Catholic seminary in Japan. He wrote the story of his life, which was published in Lisbon, and is now accepted as true, though for many years it was thought to be greatly exaggerated. He died near Lisbon, July 8, 1583.

Men'dicant Orders. See DOMINICANS, and FRANCISCANS.

Menendez de Aviles (*mā-nān'dāth dā ā-vē'lās*), **Pedro,** a Spanish admiral, was born at Avilés, Asturias, in 1519. After many years of service under Charles V. and Philip II. against French corsairs, and as commander of the Indian fleet, he was appointed commander of Florida, with orders to found a Spanish colony. His fleet of thirty-four ships, with 2,646 colonists, sailed from Cadiz, Spain, June 29, 1565. In the meanwhile a French Huguenot colony had settled in Florida. Menendez surprised the French fort and massacred the people — "not as Frenchman, but as Lutherans." He established colonies at St. Augustine, which he named Cape Carnaveral, and Port Royal harbor, South Carolina, and explored the coast as far as Chesapeake bay. While absent in Spain, a French adventurer captured San Mateo, one of his forts, and avenged the massacre of the French Huguenots — "not as Spaniards, but as traitors, thieves, and murderers." On his return, in 1572, he in turn avenged the massacre, and then explored the whole coast, until recalled by the king to command a fleet getting ready to sail against the Low Countries. He died at Santander, Spain, Sept. 17, 1574.

Menha'den, the name of a fish, a species of herring or shad, very abundant off the eastern coast of the United States. It is called whitefish, bonyfish, hardhead, and mossbunker. They are taken in nets, sometimes as many as will fill 100 barrels in a night, and sold for food, bait, and manure. They are too oily to be much used for food, but make excellent manure. The oil is used in dressing leather. The business of catching these fish and manufacturing the oil and the fertilizers from them is very large and is carried on from Maine to New Jersey.

Mennonites (*mĕn'nŏn-īts*), a body of Christian believers, named after Menno Simons, a religious reformer of the 16th century. As a sect they seem first to have drawn together in Switzerland about 1525, although they claim to be descendants of the Waldensians. Menno himself was born at Friesland about 1492, being ordained to the priesthood in his native country and serving in the village of Pinjun. In 1536, he withdrew from the communion of the Roman church and identified himself with the Anabaptists, and became a bishop of their sect at Groeningen. After enduring considerable persecution he settled down in Oldesloe, in Holstein. He died in 1559. He taught the unlawfulness of oaths, of war, of members of the church becoming civil magistrates; and he enforced so strict a discipline as to disrupt his own church. He did not himself go to any of the fanatical lengths which made the name of Anabaptists so odious in Holland, but was of a gentle disposition, modest in his personal claims and pure in his personal life. William of Orange befriended the Mennonites and gave them certain liberties in Holland, which the states afterward withdrew. In 1786 Catharine II. of Russia invited the Mennonites, with other German emigrants, to settle in her dominions, and about 350 families made their homes in the lower province of the Dneiper. They were for a time liberally aided in money, and granted perpetual exemption from military service. The privileges extended to them drew a much larger number to their Russian home, and their towns increased in numbers and wealth. As late as 1861 the emperor, Alexander II., confirmed all their ancient privileges and exemptions, and granted new lands upon the Volga. But in 1871 a new policy of repression was introduced, and exemption from military duty was to be withdrawn after the expiration of ten years. The leaders of the sect began immediately to seek new homes for their people; and large colonies emigrated to the United States, whither smaller bodies had preceded them. The earlier comers for the most part settled in Pennsylvania; the later in the Dakotas. They are already divided into various minor sects, of which perhaps the *Amish* are most frequently mentioned on account of their peculiar abhorrence of buttons, using only hooks and eyes upon their heavier garments. The census of 1890 reported only 41,000 Mennonites in the states, although this number was divided into no less than twelve sects. As this people take little or no part in political affairs, and are averse to being numbered, it is probable that their membership is considerably larger than this, as has always been commonly believed. They are sometimes classed with the Baptists on account of their practice of immersion; and oftener with the Friends, on account of their abhorrence of war.

Menominee (*me-nŏm'ĭ-nē*), **Mich.,** capital of the county of the same name, situated at the mouth of the Menominee river, on Green Bay, at the extreme southern point of the northern peninsula of Mich. It is fifty miles

north of Green Bay city, Wis., and on the Chicago, Milwaukee, and St. Paul, and the Chicago and Northwestern railroads. It is conveniently situated as a lumber-shipping port, and has a number of sawmills and other industrial activities. It has also considerable trade in the vicinity in marble quarrying and iron mining. Population 12,818.

Menschikoff (*men'shĕ-kof*), **Prince Alexander Sergeivitch,** a prominent Russian general, was born in 1787. He served in the Russian campaigns of 1812 and 1815, rising to the rank of general. He was ambassador to Persia, and fought in the war against that country. He took Anapa, in the Turkish campaign of 1828, but was severely wounded before Varna. As head of the Russian navy he brought it to a high degree of perfection. His overbearing conduct while ambassador at Constantinople, in 1853, brought on trouble between Turkey and Russia, which ended in the Crimean war. In that war he commanded both the Russian land and naval forces, and though he lost the battles of Alma and Inkerman, he displayed great energy in the defense of Sebastopol. He was recalled because of a severe illness, and was, until his death in May, 1869, a prominent member of the old Russian party, and opposed to all reforms.

Mentone (*men-tō'nā*), a French seaport town, is situated on the Mediterranean, near the borders of Italy, 14 miles from Nice. On the north and west, the spurs of the Alps, 3,000 or 4,000 feet high, shelter it from the winter storms, so that the climate is mild, making it a favorite winter resort for invalids. It is surrounded by beautiful suburbs, and by olive groves and plantations of oranges and lemons. The trade of the region is largely in olive oil, lemons, oranges, and wine. At the eastern end of the bay are the bone-caves, about 88 feet above the Mediterranean in which many curious remains are found, belonging to prehistoric times. Mentone belonged to Monaco up to the year 1848, when the inhabitants put themselves under the protection of Sardinia. Twelve years later (1861) Sardinia ceded the town to France. Population about 10,000. See *Winter and Spring on the Shores of the Mediterranean*, by Bennet.

Men'tor, the son of Alcimus, the friend of Ulysses, to whose care that hero intrusted his son Telemachus when setting out for the Trojan war. On account of the fidelity with which he discharged this trust, his name became a synonym for one chosen to be a guide or instructor of youth.

Mephistopheles (*mef-is-tof'e-lēs*), in old legends a character representing the principle of evil, or another name for the devil. The name is thought to be derived from the Hebrew, and means "one who loves not light." The character is best known from its appearance in Goethe's *Faust*.

Mercator (*mer-kā'tor*), **Gerard,** a Flemish geographer of the 16th century, was born at Rupelmonde, Flanders, March 5, 1512, his real name being Kræmer, "merchant," of which Mercator is the Latinized form. He took his degree as bachelor of philosophy at Louvain, but devoted his later years to the study of geography. In 1559, he was appointed cosmographer to the duke of Cleves. He published several important works, including maps and descriptions of France, Germany, and Great Britain. He did a great deal to put geographical science upon a secure footing and to make popular the researches of the learned. Some of his later works were of a religious character and were supposed to favor the Reformed doctrines. He died in Prussia, Dec. 2, 1594.

Merca'tor's Projec'tion is a name given to that kind of map-making in which the meridians of longitude are drawn as if parallel, the circles of latitude being in consequence all at right angles with the same. In order to lay down the sailing course of a vessel, which is in fact a curve, so that it shall be represented as a straight line, and the angle of the course be readily measured upon the chart, it is necessary to represent the surface of the earth as a plane instead of spherical. This requires, of course, that the degrees of longitude, which vanish at the poles, should be represented as the same length that they are at the equator. In order to draw a chart upon which all sailing courses may be represented by straight lines, sea-maps are constructed according to the scale devised by Mercator, the distances as we go toward the pole being immensely exaggerated. The amount of these exaggerations are taken from a table of meridional parts. Given then the starting point of a ship and its meridian and latitude at the close of the day, a straight line between these two points found upon a Mercator's chart would indicate its course, and lines drawn parallel with the meridian passing through the termination and one parallel with the latitude of the starting point would form at their junction a right angle. The angle of the course sailed would be found by measuring the angle at the base.

Mer'cury or **Hermes,** in Greek mythology, the son of Zeus and the messenger of the gods. He was the patron of the thieves, of travelers of merchants, of rain, of good fortune, and of eloquence, and is sometimes called the god of the wind. He began his career by stealing the oxen of Apollo when only a few hours old, and inventing a lyre out of a tortoise shell at the same early age. He was connected with the every-day life of the Greeks more than any other god. His images were found on mountains, by streams, in the streets of their cities, over the doors of their gymnasiums, and were used as guide-posts on their roads and to mark the boundaries of their states. He is represented in art

with a staff, wings on his feet or shoulders, and a low, broad-brimmed hat on his head. Some of the most beautiful specimens of Greek art are statues of Hermes, notably one by Praxiteles. Mercury is the Latin name for the Greek god Hermes.

Mer'cury or **Quick'silver** is the only metal that is fluid at common temperatures, which gives it its name, meaning fluid silver. It is of a silvery-white color, and runs on a smooth surface, in separate round drops. If it is not pure, the drops will leave a trail. Heat expands it, and cold contracts it regularly down to its freezing point, which is about 40° below 0°, which explains its use in a thermometer, the range being more than 700 degrees between the boiling and freezing points. When boiled, mercury forms an invisible vapor. Native mercury or quicksilver occurs in small quantities, usually in connection with mercurial ores. These ores, of which the most important is called cinnabar, are burned in a furnace, and the sulphur, which is combined with the mercury, passes off as sulphurous acid, and the mercury can be collected in a condensing chamber. The Greeks and Phœnicians procured cinnabar from Almaden, Spain. After the discovery of America, the mercury of Peru was famous. The larger part of the mercury used in America comes from California, and most of it from one mine, called the New Almaden. Mercury unites with other metals to form what are called amalgams, and this property is made use of in extracting gold and silver from their ores. The amalgam of mercury and tin is used in silvering mirrors, while others are used in gilding and filling teeth. It is used largely in the making of philosophical instruments and in the laboratory, and some salts of it are used in medicine and as antiseptics.

Mer'cury. See PLANET.

Mer de Glace (*mâr de glâs*), Switzerland, one of the most noted of Apline glaciers. At a distance, only a part of this vast "sea of ice," can be seen, but there are miles upon miles of pulverized rocks ground off from adjacent cliffs and piled up on its sides. Among these are bowlders 20 or 30 feet square, which have been tossed about like mere playthings and landed here. The "sea of ice" lies between these tracts of earth and stones, white and glistening, and looks as if its billows had been instantly frozen, while their crested waves were wildly tossing. Some of these are gigantic, for as the glacier pushes down toward the valley it is distorted into monstrous forms by various obstructions in its way. Some of these glistening waves are more huge than any cathedral built by man. As this frozen mass descends in the fertile valley, it steals between the pastures and close to the trees and hayfields of the meadows, so that one may swing a scythe or gather flowers only a hundred yards away from a deep crevasse, which is a death trap, swallowing its hapless victims every year.

Mer'edith, George, an English novelist and poet, was born in Hampshire, England, Feb. 12, 1828. His first writings were poems, published in 1851, followed in 1855 and 1857 by stories. The series of works for which he is best known began in 1859 with *The Ordeal of Richard Feverel.* Others of his best known works are *Rhoda Fleming*, *The Egoist*, *Adventures of Harry Richmond*, *Vittoria*, *The Tragic Comedians*, and *Diana of the Crossways*, the latter being deemed the most charming of his novels. His later poetry is in three small volumes, *Poems and Lyrics of the Joy of Earth* (1883), *Ballads and Poems of Tragic Life* (1887), and *A Reading of Earth* (1888). His later novels include *One of Our Conquerors*, *The Amazing Marriage*, *The Tale of Chloe*, and *Lord Ormont and His Aminta.* While not a popular writer (for his style is difficult), Meredith ranks among the foremost novelists of the day. See *George Meredith*, by Le Gallienne; *Some Characteristics*, by John Lane.

Merida (*mer'ē-dd*), a city of Mexico, the capital of Yucatan, is situated on the gulf of Mexico. It was founded by the Spaniards in 1542 on the site of an ancient city. It has a cathedral, finished in 1598, a university, conservatory of music, museum, and public library. Its manufactures are largely molasses, sugar, cigars and cigarettes, rum, leather, and soap. Population 36,935.

Mer'iden, a city of Connecticut, 19 miles north of New Haven. It was made a town in 1806 and a city in 1867. It is a manufacturing place, principally of metal wares, cutlery, firearms, carriages, and woolen goods. The Meriden Britannia company, founded in 1852, covers ten acres of floor space with its factories. It manufactures silver-plated ware and is the largest establishment of the kind in the world. Its well-known trade mark, "1847, Rogers Bros.—A1," is a guarantee of good material and honest work. Population 24,296.

Merid'ian, from *meridies*, midday, noon, is the name given to the great circle passing through the earth's surface and the celestial sphere, which passes through both poles of the heavens, and the zenith and nadir of any place on the earth's surface. Every place, on the earth's surface has, therefore, its own meridian. When the center of the sun comes upon the meridian of any place it is midday, or noon, there. And as it is midday at all places directly under that meridian, it is midnight at all places directly opposite upon the other side of the globe. All places under the same meridian have therefore the same longitude. Stars are measured as to their distance from the celestial meridian. In making a map some place is arbitrarily chosen, as Greenwich or Washington, from which longitude is computed by measuring the distances

in degrees of their meridians from each other. Since the vast development of railways in the United States it has become more and more important to have all watches mark the same time within certain geographical limits. In consequence, certain meridians have been chosen by the railway authorities as standards of time; and all watches between such meridians, one hour of the sun's journey, or part, are set alike. When the distance between two such standard meridians has been traversed, timepieces are reset so as take up or strike off an hour.

Meri'dian, Miss., a town in the cotton belt, the capital of Lauderdale county, in eastern central Mississippi, 85 miles east of Jackson, and 135 miles northwest of Mobile, Ala. It has a number of educational institutions, including the Meridian academy (Methodist Episcopal); Meridian Normal college; and East Mississippi Female college [Methodist (Southern) Episcopal]. Its commerce is chiefly in corn and cotton, and it has a number of industries, including steam corn mills, and establishments for the manufacture of cotton yarn, plows, doors, sashes, blinds, and general furniture. Population 14,050.

Meristem (*mĕr'ĭ-stĕm*) (in plants), young tissue whose cells are capable of division, which results in a multiplication of cells. The growing points of stems and roots consist of meristem or meristematic tissue, which produces all the tissues which appear in the mature stems and roots. The canbium (which see) in stems is a kind of meristem, which has the power of forming new wood on one side and new bast on the other. All growing organs are meristematic throughout or in some special part until they are fully grown. An appropriate phrase describing meristem is "formative tissue."

Mer'ivale, Charles, an English divine and historian, was born in Devonshire in 1808; and died Dec. 27, 1893. He was educated at Cambridge, where he became both fellow and tutor. He was the preacher for the university from 1838 to 1850, and delivered lectures there in 1861 and again in 1864. In 1869 he was appointed dean of Ely. His chief works are *Fall of the Roman Republic*, and *History of the Romans under the Empire*, in seven volumes. He has written also a *General History of Rome, Early Church History*, and *Contrast between Pagan and Christian Society*, with a translation of Homer's *Iliad*.

Mer'lin, an ancient British bard, prophet, and magician, who lived in the 6th century. He was the son of a Welsh princess, and is said to have had miraculous powers from his birth. There are many allusions to him in early English poetry and history; in Spenser's *Faerie Queene*, and later in Tennyson's *Idylls of the King*. A collection of his prophecies was printed in the 16th century in French, English, and Latin.

Mer'maids, in popular legend, a class of beings part woman and part fish. They live in the sea, but are represented often as seated on the rocks,—a lovely woman with a human head and body ending in a scaly fish's tail. She has long, beautiful hair, which she combs with one hand, holding the mirror above the waves with the other. They sometimes seem to have exercised a special care of individuals, and often revealed future events. There are stories of their falling in love with men and remaining faithful wives and mothers for a long season, until they found a chance of returning to the sea, and also of enticing their lovers to their ocean homes. The beautiful romance of *Undine* and the story of Melusine are founded on the ancient belief in mermaids. See *Popular Myths of the Middle Ages*, by Baring-Gould.

Merovingians (*mer-ō-vin'jĭ-anz*), the first dynasty of Frankish kings in Gaul. The name was derived from Merwig, or Merovech, king of the western Franks who ruled from 448 to 457. Clovis, the first Christian monarch of the Franks, and Dagobert, are the names best known in history. The dynasty ended with Childerick III., 742–752, who was deposed by Pepin the Short, who founded the Carlovingian dynasty. See *History of France*, by Yonge; *Franks, to the Death of Pepin*, by Perry.

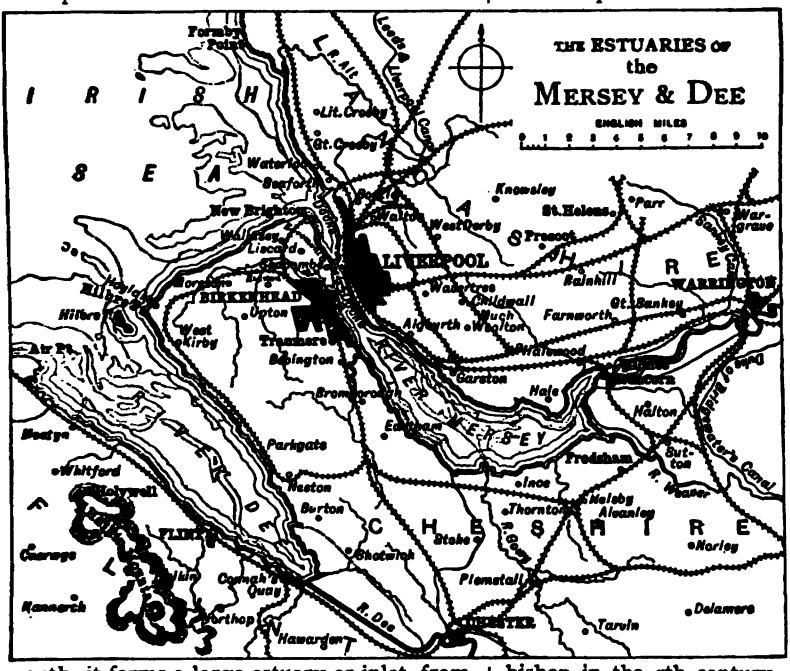
Mer'rimac, a river of New Hampshire, formed by the union of the Pemigewasset and Winnepiseogee rivers at Franklin, New Hampshire. It flows south into Massachusetts, emptying into the Atlantic ocean near Newburyport. Its numerous falls give a great water-power, which has made the manufacturing towns of Nashua and Manchester, New Hampshire, and Lowell and Lawrence, in Massachusetts. It is navigable for 18 miles to Haverhill.

Mer'ritt, Wesley, an American soldier, a major-general in the United States army, was born at New York, June 16, 1836, and graduated from West Point in 1860. Going into service as a second-lieutenant of cavalry, he was promoted to a first-lieutenancy in the infantry in the next year, and made a captain in the year following. At the close of the war he held a commission as lieutenant-colonel in the regular army and was a brevet major-general of volunteers. Since the close of the Civil war he was promoted in regular order of service through successive grades until he was made major-general U. S. A. He commanded a cavalry division in the Shenandoah campaign and rendered conspicuous service at Five Forks, Gettysburg,

GEN. W. MERRITT.

Fisher's Hill, etc. He was one of the three commanders chosen from the Federal army to arrange terms of surrender on the part of the Confederate army of Northern Virginia. After years of service in Indian campaigns in the territories of the west, he was assigned, May, 1898, to the command of the United States forces in the Philippines.

Mersey (*mer'zi*), an important river of England, flowing into the Irish sea, near Liverpool. About seventeen miles from its



mouth, it forms a large estuary or inlet, from two to three miles wide. The river has been made navigable from Liverpool to Manchester, by a ship canal, while a railroad tunnel, connecting Liverpool and Birkenhead, passes under it. The country along its banks is very fertile, and by walls along parts of the river that were subject to overflow, many thousand acres have been reclaimed. The river is 70 miles long.

Merthyr-Tydvil (*mer'ther-tid'vil*), a market town in Glamorganshire, on the river Taff, South Wales, 24 miles north of Cardiff. It is in the mining region of South Wales and is built largely on a foundation of slag—the refuse of the neighboring mines. It was originally made up of houses for the workmen in the mines and collieries, but has lately been very much improved, the streets being widened, pure water and good sewerage introduced, and one of the finest and largest market-places in Wales established in the center of the town. The business of the place is all connected with the iron and steel works and collieries. The name comes from the martyrdom here of a Welsh princess, named Tydvil or Tydfil. Population 60,861.

Merv, an oasis in Turkestan, Central Asia, near the northeast corner of Persia. It is sixty miles long and forty wide, and crossed by the river Murghab; its area being 1,600 square miles. It has a hot, dry climate and produces wheat, sugar, cotton, and silk. About a quarter million of Turkomans live in the oasis, where there is also a town called Merv, and a Russian fort opposite, with a garrison of 3,000 men. The men are workers in silver, and breed horses, sheep, and camels, while the women weave silk and make carpets. The country is mentioned in the earliest writings of the Persians, and Alexander the Great built a town in it. The Parthians, Arabs, Turks, Mongols, Persians, Turkomans, and Russians have held it at different times. It was the seat of a Nestorian archbishop in the 5th century, of a Greek archbishop in the 14th, and in the 8th century was the headquarters of the "veiled prophet of Khorasan." The Russians, who have held it since 1883, have built a railroad across it from the Caspian sea to the Oxus river. The oasis is distant 200 miles from Herat. See *The Merv Oasis*, by O'Donovan.

Meshed (*mesh'ed*), (place of martyrdom), is the principal city of northeastern Persia. It is the capital of Khorasan, and the sacred city of the Shiites, a sect of Mohammedans, 100,000 pilgrims visiting it yearly. It is surrounded by a wall twelve miles long, above which shine, as the city is approached, the gilded dome and minarets of one of the most magnificent mosques of the east. There are also splendid sepulchres of Haroun-al-Raschid and Nadir Shah, and near by that of Firdusi, the Persian poet, another large mosque, several colleges and a palace. Rugs, carpets, velvets, swords, and silk and cotton goods are manufactured, and turquoise

jewelry from the turquoise mines of the region. Population 60,000. See *Persia*, by J. Bassett, and Benjamin's *Persia and the Persians*, in the "Story of the Nations" series.

Mes'mer, Friedrich Anton, a German physician, was born near Constance, Switzerland, May 23, 1733. He studied medicine at Vienna, and, when he took his degree, presented a paper in which he introduced tentatively his theory of animal magnetism. Studying the properties of the magnet still further, in 1772 he concluded that there was a power in the universe like magnetism, which exercises a secret influence on the human body, which he called animal magnetism, and which is also called mesmerism. In 1775, he published an account of his discovery, and in 1778 went to Paris, where he created a great sensation and received large sums of money. The French government offered him the use of a hospital and a pension of $4,000 yearly, if he would instruct three assistants in his new methods, but he refused to reveal his secret. The government appointed a commission in 1785 to investigate the system. This commission, composed of such men as Benjamin Franklin, Lavoisier, Bailly, etc., reported unfavorably, and he lost his pupils and a large practice, retiring to Switzerland, where he died at Baden, March 5, 1815. See *Mesmer the Magnetiser*, by P. Anderson-Graham.

Mesophyll (*mĕs'o-fĭl*), (in plants), the tissue of foliage leaves whose cells contain chloroplasts. As a consequence, the mesophyll is the essential working tissue of leaves, and gives to them their green color. It is bounded above and below by colorless epidermal layers, and is traversed by the vein system. See LEAF.

Mesophytes (*mĕs'o-fīts*), plants which live in conditions of medium moisture and fertile soil. They are distinguished in this regard from the hydrophytes or water plants, and the xerophytes or plants of dry soil and air. Mesophyte conditions are those which are best adapted to plants which man cultivates. In case an area is hydrophytic, it is drained and made mesophytic; in case it is xerophytic, it is irrigated and made mesophytic. In contrast with hydrophytes and xerophytes, the mesophytes are far richer in leaf forms. All of the societies which man has formed by his introduction of weeds and culture plants are mesophytic. Among the more conspicuous mesophyte societies the following may be mentioned: "arctic and alpine carpets," characteristic of high altitudes and latitudes, where the conditions forbid trees and shrubs or even tall herbs; "meadows," which are areas dominated by grasses, the prairies being the greatest of meadows; "thickets," composed of willow, alder, birch, etc., either pure or forming a jungle of mixed shrubs, brambles, and tall herbs; "deciduous forests," which are the pride of the temperate regions, rich in forms and leaf display, with autumnal coloration and annual fall of leaves; "rainy tropical forests," in the regions of trade winds, heavy rainfall, and great heat, where the world's vegetation reaches its culmination, and where dense growths are developed, composed of all sorts of trees, shrubs, and herbs bound together in an inextricable tangle of great vines.

Mesopotamia (*mes'ō-pō-tā'mi-ā*), a country of western Asia, lying between the Tigris and Euphrates rivers, whence its name, meaning "between the rivers." Its area is about 55,000 square miles, with a level surface and sandy soil, and when irrigated, as it was in ancient times, is very fertile. Bagdad (population 145,000) is its capital. Upper and Lower Mesopotamia to-day include not only the Turkish vilayet or province of Bagdad, but also Mossul and Bassora, with a total area of 100,205 square miles, and a population of 1,350,300. Since 1515, when it was conquered by the Turks, it has been neglected, and has become barren. The present population are Arabs and Kurds, who keep herds of camels, sheep, and goats, and raise wheat, barley, millet, cotton, tobacco, and hemp. Wild hogs, jackals, hyenas, and foxes abound, but the wild asses and lions of ancient times have disappeared. The country has belonged at different times to the Assyrians, Babylonians, Persians, Greeks, Romans, Arabs, and Turks, and has often been the battlefield of these great empires. Among the ancient cities of the region were Harran and Nineveh, and of modern ones are Mardin, Mosul, and Diarbekir. The excavations being made at Nineveh and other ancient ruins are adding much to the knowledge of the region and its early inhabitants.

Mesquite (*mĕs-kēt'*) (the *Prosopis Juliflora*) is a spiny shrub or small tree, found in Texas and throughout the semi-arid southwest, of the family *Leguminosae*. Its wood is hard and it affords good fuel in limited quantities, while its gum supplies a fair substitute for gum Arabic. The long pods offer a sweet, thick, and fairly palatable pulp. Bark and wood are used for tanning. The curly mesquite, or screw bean, is larger than the common mesquite, although scarcely large enough to be called a tree, growing in company with willows near springs of water. Its pods are from an inch to an inch and a half in length and twisted into a rigid cylinder. The beans are eaten by the Indians of the plains. Certain coarse grasses of the southwest are often called mesquite-grass. They are valuable to stock men, but of little value when cut.

Messina (*mĕs-sē'nā*), the sacred city and seaport of Sicily, lies on the western shore of the strait of Messina. The city rises from the sea in the shape of an amphitheatre, its white houses standing out in relief against a background of hills. The city, although ancient, has few antiquities, as it was overrun by armies, and nearly destroyed by an earth-

quake in 1783. It has one of the finest harbors in the world, which is entered yearly by nearly 3,500 vessels. The industries are the manufacture of linen, muslin, and silk goods, the working of coral, and making of fruit essences; the exports are largely fruits and articles made from fruit, such as olive oil, wine, and essences. There is a cathedral, erected first in 1098, and since rebuilt; a citadel built in 1680, and a university founded in 1549, with churches, colleges, and academies of art and science. The city was founded in 732 B. C., and the Carthaginians destroyed it in 396 B. C. After Carthage was conquered by the Romans, it belonged to the Roman empire, until the Saracens took it in the 9th century. They were expelled in the 11th century by the Normans; and from 1282 to 1713 the Spaniards held it. In 1743, the plague, and in 1783 the earthquake, completed its ruin. In 1848, it was bombarded by the Neapolitans, and in 1861 was the last place in Sicily to yield to Italy. Population 156,552.

Metabolism (*mē-tab'o-liz'm*) (in plants), a term covering all the chemical processes taking place in the living organism. Some of these processes are constructive, *i. e.*, the resulting substances are more complex than before; others are destructive, the resulting substances being simpler than before. Thus constructive metabolism occurs when a green leaf, acting on carbon dioxide and water under the influence of light, forms sugar, a complex food, and when by further changes this food is built up into living protoplasm. But in respiration protoplasm is decomposed, and carbon dioxide and water, with other less known products, are formed. This is destructive metabolism. The products of metabolism are so many as almost to defy enumeration. See, for example, the thousands in medicinal use described in the United States Pharmacopœia.

Metallurgy (*met'al-lur'jy*) is the science which deals with the extraction of metals from the ores in which they are found in mining. Some metals are found as such, and are then said to be free, native, or virgin metals. Gold and platinum usually occur free; silver, copper, and bismuth are often found so. The other metals, such as iron, lead, tin, zinc, nickel, mercury, antimony, and aluminum invariably, or almost invariably, occur "mineralized," that is, in combination with other elements as oxides, sulphides, sulphates, carbonates, silicates, chlorides, etc.

Ores, as they are found and mined, usually contain large quantities of worthless materials, called "gangue," consisting of common rocks and minerals. Such ores are often washed by various machines called jigs, vanners, etc., in order to separate or *concentrate* the valuable material. In this process the lighter gangue is carried away by water and the heavier valuable minerals are collected. It is usually necessary to crush the ore and sort it by sieves before the operation is carried out. Where free gold occurs in sand or gravel a simpler method of washing is used. A stream of water carries the material through a long trough or "sluice," the bottom of which is provided with grooves or "riffles" in which quicksilver (mercury) is placed. The heavy gold sinks to the bottom, and is there held by the mercury as an amalgam.

Treatment with mercury or *amalgamation* is often applied to compact ores of gold and silver in stamp mills, which consist of arrangements like mortars and pestles worked by machinery. The stamping is usually done in the presence of water, and as fast as the ore becomes fine enough it passes with water through screens and over copper plates covered with a layer of mercury where the valuable metals are caught. Mercury is also placed on plates within the mortar. Ores containing sulphides, tellurides, etc., require heating in contact with air, or *roasting*, to burn off sulphur and other impurities before they are treated by amalgamation. Common salt is usually added to silver ores of this kind before roasting.

Certain gold and silver ores are powdered and leached, or "lixiviated" with solutions of chemicals to dissolve out the precious metals. For instance, a weak solution of potassium cyanide is used to dissolve free gold in the *cyanide process*, and solution of sodium hyposulphite is employed to dissolve silver chloride from ores that have been roasted with salt.

The most important metallurgical process is *smelting*. In this operation the ore, often after it has been concentrated, and frequently after it has been roasted, is mixed with a *flux*, if necessary, and melted at a high temperature. The earthy materials of the ore with the flux form a fluid *slag*, while the action of the fuel, or other chemical action, produces a molten *metal* in some cases, or in other cases a fused mixture of sulphides, called *matte*, which is much richer than the original ore in the amount of valuable metal it contains. In iron smelting the ore, mixed with coke or coal as fuel and with limestone as flux, is fed in at the top of an enormous blast furnace, a structure somewhat like a barrel in shape, but more slender, and much narrower at the bottom than elsewhere. Hot air, forced in through pipes near the bottom of the furnace, burns the fuel and produces great heat. Metallic iron and slag are formed, and are allowed to flow out from time to time through holes near the bottom; the metal, being heavier, runs out through a hole that is lower than the one used for the slag. The metal is called pig iron, and is used in foundries for making articles of cast iron, as well as for making wrought iron and steel. See IRON, and STEEL.

Copper ores are smelted in blast furnaces that are much smaller than those used for

iron. They are also sometimes smelted in *reverberatory furnaces*, in which the heating is accomplished by the flame from a coal fire made in a separate compartment of the furnace or by means of gas. With certain copper ores, such as those containing the oxides or the carbonates, metallic copper may be the direct product of smelting, but the very common ores containing sulphides are at first smelted for copper matte, which consists chiefly of the sulphides of copper and iron. The metal is extracted from the matte by operations in which air at high temperatures burns out or oxidizes the sulphur and iron. When gold and silver are present in copper ores, the precious metals are found in the metallic copper produced from them, and are recovered by electrolytic refining, which consists in dissolving the metal and re-depositing it by means of an electric current acting in an appropriate solution. The gold and silver, and some other impurities, are left undissolved in a finely-divided condition.

Lead smelting is carried out both in reverberatory furnaces and in blast furnaces. When galena, lead sulphide, the most common lead ore, is obtained nearly pure, either directly from the mine or by concentration, it is frequently smelted by roasting it on the bed of a reverberatory furnace until it is partly changed to oxide and sulphate, then raising the heat to fusion and thus causing the oxidized part to act upon the remaining lead sulphide with the formation of metallic lead and sulphur dioxide gas. The smelting of lead ores in blast furnaces is carried out particularly for the sake of obtaining the silver that the ores usually contain, and also for obtaining the silver from ores containing little or no lead, which are purposely mixed with lead ores with this end in view. If a sufficient proportion of lead is produced, practically all the silver (and the gold also) in the ores goes into the lead. The greater part of the silver produced in the world is extracted by lead in this way. If the ores contain sulphides, they are roasted before they are smelted in the blast furnace. Coke is the usual fuel, and limestone and iron ore are generally used as fluxes. The silver which lead contains is usually extracted by dissolving small quantities of zinc in the hot, molten metal. As the metal cools, the zinc becomes solid, then it rises to the surface, bringing the silver with it, and is skimmed off.

The metal zinc cannot be obtained by ordinary smelting processes, because it boils and is vaporized at the temperature at which it is reduced to the metallic state. This metal is therefore obtained by first roasting the ore, if it is the usual sulphide, and then heating it with coal in retorts made of fire clay. The zinc distills off and is condensed and collected.

A distillation process is also used for obtaining the volatile metal mercury from its ores.

Aluminium is not reduced to the metallic state from its compounds by the ordinary smelting processes. The principal method of producing it consists in passing a powerful electric current through melted cryolite in which aluminium oxide is dissolved.

The processes used for obtaining several other metals are similar to those that have been mentioned.

Metallurgy is a very ancient art that has been gradually developed and improved during historical times, but the greatest improvements have been made during the past century, and they have been largely due to the assistance afforded by advancing knowledge of engineering and of chemical and physical sciences. HORACE L. WELLS.

Met'als. See GOLD, SILVER, LEAD, IRON, etc.

Meteorology (*mē'tē-ēr-ŏl'ō-jy*), the science which deals with the phenomena of the earth's atmosphere. These phenomena may be grouped under three different heads, namely, *aërial* phenomena, including winds, cyclones, etc.; *aqueous* phenomena, such as rain, fogs, clouds, etc.; and *luminous* phenomena, such as lightning, the aurora borealis, etc. This science, which is one of enormous importance to the human race, is universally recognized as yet in an embryonic state. For the various subjects ordinarily grouped under this head, the student is referred to numerous individual articles, such as FOG, CLOUD, CYCLONE, LIGHTNING, etc., scattered throughout this work.

Me'teors are small bodies traveling in large numbers and in many directions through space. They are known as aërolites, fireballs, and shooting stars, and may be seen every clear night, sometimes a few only, and at other times in showers. The whole number which the earth meets in one day's travel through space is estimated at 7,500,000, but as this large number weighs in all only 100 tons, many of the meteors must be very small. The air acts as a shield, and offers so much frictional resistance that the meteor generally burns up in the air. The aërolites are the large masses which actually fall to the earth. Some of them are of iron, some of stone, and some of stone and iron. When their fall is noted, there is always a noise, as of an explosion, and a cloud or smoke and a melting of the mass, at least on the surface, showing the action of heat. The iron is combined with nickel, cobalt, copper, etc., in a different way from any combination found on the earth, though no new element has been discovered. The falls of aërolites have been more numerous than might be supposed, the British Museum having over three hundred specimens of them.

The fireballs are brightly-shining bodies seen crossing the sky, and are considered to be aërolites before their explosion and fall. Many hundreds have been observed, Arago giving a list of over eight hundred. They are of all sizes, and travel about 26 miles a second. Shooting stars may be seen on

almost any evening, and if carefully watched will seem to come from the same point in the sky. These points are called *radiants*, and are named for the constellation in which they are found — as the Leonids, a group whose radiant is in the constellation Leo. When there is a meteoric shower, the earth is passing through a group or swarm of these meteors, which are also moving as the earth does, in an orbit of its own. The Leonids, which are seen in November, are calculated to move round the sun once in 33¼ years, the earth crossing their track every year, but only meeting the main swarm when it reaches the point of crossing at the same time as the earth. When this happens, there is a meteoric shower, such as took place Nov. 13, 1833, when the stars fell like snowflakes and fireballs darted back and forth, making the most wonderful display of the kind ever seen. Astronomers predicted another shower in 1866, and it came within a few hours of the time agreed upon. The latest investigations point to a common origin for these meteors and the comets, or rather indicate that meteoric swarms are composed of disintegrated comets. Besides the great November group, other groups are active in August, April, September, and October. See Young's *General Astronomy*.

Meth'uen, Paul Sanford (Baron, C.M.G), a lieutenant-general in the British army, who distinguished himself in the Boer war, was born in 1845, and entered the Scots guards as lieutenant in 1864. In 1873, he was sent on special service to the Gold Coast, and in the following year became brigade-major at Ashanti. In 1877, he acted as assistant military secretary to the English commander-in-chief in Ireland, and from 1877 to 1881 was military attaché at Berlin. For the next three years he was assistant quartermaster-general for the home district in Britain, commandant at headquarters in Egypt, and commander of Methuen's horse and the field force during the Bechuanaland expedition of 1884–85. In 1888, he was deputy adjutant-general in South Africa, and from 1892 to 1897 commanded the Home district. On the outbreak of the war with the Transvaal and Orange Free State, he was given command of the first division of the army corps, sustaining the severe defeat at Magersfontein, after several dearly-bought victories.

Metre (*mē'tĕr*), the standard of length employed by all civilized nations, except England and the United States. This standard was prepared by the government of France about the time of the French revolution, and was intended to be equal in length to one ten-millionth part of the earth's quadrant passing through Paris. This length was ruled on a bar of platinum and is correct, by definition, at °°C. It is known as the *mètre des archives*. More recently, an international commission has prepared copies of this metre on bars of a platinum-iridium alloy. These copies have been distributed to various nations, and constitute the national standards of length. The unit of length most universally employed in science, is one one-hundredth part of the distance between the two end rulings on the metre bar. This unit is known as the *centimetre*.

Metronome (*mĕt'rō-nōm*), an instrument for dividing or "beating" time, used chiefly in the study of music. As ordinarily constructed, it looks like an inverted pendulum swaying before a pyramid, the pendulum being moved by clockwork, and the motion retarded or accelerated by sliding up or down a metal weight appended to the wire. If this weight be near the point of suspension the motion will be rapid; if near the top, correspondingly slow.

Metternich (*met'ter-nik*), **Clemens Wenzel Nepomuk Lothar,** Prince, an Austrian statesman, was born at Coblentz, Prussia, May 15, 1773. He studied at Strasburg and Mainz (Mayence). He was first connected with the Austrian embassy at The Hague, and came into notice at the congress of Rastadt. He was appointed Austrian minister to Dresden when he was twenty-eight, and two years later became ambassador to Berlin, and after the peace of Presburg was sent as minister to the court of Napoleon. "You are very young to represent so powerful a monarchy," said Napoleon, when he presented himself. "Your majesty was not older at Austerlitz," he answered, showing in his answer the skill and knowledge of character which gave him power. He concluded the treaty of Fontainebleau in 1807, and in 1809 became minister of foreign affairs, and while in that position negotiated the marriage of Maria Louisa of Austria with the Emperor Napoleon. He was made a prince of the empire in 1813, and in 1821 became chancellor. The French revolution, in spite of his resistance, was felt at Vienna, and Metternich was compelled to flee to England, where he remained until 1851. After his return, he took no part in public affairs, and died at Vienna, June 11, 1859. In 1880–84, his *Memoirs* were published in eight volumes. See *Metternich*, by Malleson, in the "Statesmen" series.

Metz (*mets*), the capital and strongest fortified town of Lorraine, Alsace-Lorraine, Germany, on the Moselle river. It has a series of forts around it, which have been strengthened since the annexation of Lorraine to Germany. It has a fine cathedral founded in the 14th century, with a beautiful open spire, 363 feet high. The making of saddles, shoes, and tanning, are the manufactures of the town; and the trade is largely in wine, brandy, and preserved fruits. Metz was known to the Romans as Mettis, and became a free city under the Franks, and was famous for its commerce, and its literature

and art. In 1552, it was taken by the French, to whom it was formally ceded in 1648. In the Franco-Prussian war, of 1870, it was occupied by Bazaine, who, after a long siege, surrendered it to the German army and by the treaty of Frankfort it became a German city. The population is more than half Catholic, and has decreased by emigration into France since the annexation to Germany. Population 59,794.

Meuse (*mūz*), a river which rises in France, flows north to Belgium, and into Holland. Turning to the west it joins the Waal, one of the mouths of the Rhine, and becomes the river Maas. It soon divides again, one branch reaching the sea in two wide inlets, while the northern branch also divides and enters the sea through two channels called the Old and New Maas. Rotterdam stands on the New Maas. The river is 500 miles long.

Mexico (*mek'si-kō*), a city of Mexico, and capital of the republic, is situated in the midst of the central tableland of the country, 7,347 feet above the sea. The city is built in a valley, surrounded by hills and six lakes, of which Lake Texcuco is the largest. The principal streets are broad and well-paved, and paved roads, planted with double rows of trees, stretch far into the country in all directions. All the main streets radiate from the central square, once occupied by the great temple of the Mexican god, Huitzilopochtli, and now filled by the grand cathedral, founded in 1573, with twenty chapels, and towers and walls costing alone $2,000,000. The famous Aztec Calendar Stone is built into one of the towers. On the square are also two palaces, the post office, and national museum, with one of the finest collections of pictures in America. A monument to Columbus was erected in 1877, and there is also one to the last of the Aztec emperors. On the lakes around the city are still a few of the floating gardens for which the place was once famous. The city has a few manufactures, such as cigars, gold and silver work, pottery, etc., but its trade is largely that of a market for the surrounding country. The site is unhealthy, and many efforts have been made to drain the basin in which the city stands, the latest by an English company in 1890. The climate is pleasant, ranging from 70° to 50°. Mexico is known in history as the capital of the Montezumas, founded by the Aztecs in 1325. The city was in its full glory when Cortez conquered it in 1521, destroying a large part of the ancient town. He rebuilt it on its present plan, using a company of 400,000 Indians in the work. It was occupied by the Spaniards for 300 years, and since the establishment of the republic has been the scene of revolution and the battlefield for contending armies. Population 329,774.

Mex'ico, a federative republic in the most southern country of North America, lying between the United States and Guatemala. It is as large as Great Britain, France, Germany, and Austria together, and is 2,000 miles long, and from 130 to 1,000 miles wide. Lying between the gulf of Mexico and the Pacific ocean, it has a coast line of 6,000 miles, but only one good harbor, Acapulco. The peninsulas of Yucatan and Lower California belong to it. The country is, in the main, a great tableland, reaching a height of over 8,000 feet, sloping abruptly to the Atlantic coast, and more gradually to the Pacific. The most important range of mountains are the Sierra Madra, over 10,000 feet high, though there are several lower ranges, some running the length of the country, and some crossing it. The most elevated peaks are Toluca (19,454 feet), the highest point in North America; Orizaba (18,205) and Popocatapetl (17,523). Ten of the highest peaks are volcanoes, but they are nearly all extinct. The rivers of Mexico are of little use, being usually mountain torrents, which flow through rocky gorges 1,000 feet in depth. The largest is the Rio Grande, which forms part of the United States boundary. The climate of Mexico varies from that of the lowlands, which are tropical, to that of the tableland, which is perpetual spring, and one passes through all degrees of temperature in a few hours in going from Vera Cruz to the city of Mexico. The highest peaks are in the region of perpetual snow. The atmosphere is dry, and large parts of the agricultural regions are dependent upon irrigation; but when well-watered yield enormous crops, and often two crops in a season. The rainfall is scanty, and in the southern parts of the state there are two seasons, the wet and the dry, the wet season lasting from June to October. The products of the country are, like its climate, very varied. In the forests are palms and the India-rubber tree, as well as pines and evergreen oaks. The tropical fruits grow in abundance, with cotton, sugar cane, and coffee, while higher up are harvested large crops of wheat, corn, and barley. The yield of corn is enormous, and sometimes three or four crops are obtained in one year. The methods of farming are as a rule primitive, and the resources of the country have not begun to be developed. In the northern part cattle raising is carried on. Manufactures are few, though they supply the local demand. Foreign capital, however, is entering the state, and will soon change the trade of the country. Cotton, flour, sugar, tobacco, mahogany, and pottery are manufactured and exported. The bulk of the Mexican trade is in minerals, of which Mexico has larger supplies than any other country, including gold, silver, lead, iron, copper, zinc, quicksilver, and platinum. There are large deposits of gypsum, marble, alabaster, and rock salt. A mountain near Durango is a solid mass of magnetic iron ore. Mexican ores were formerly carried to the United States for smelting, but since the duty on the ore be-

came large, American foundries and metal works have been established in Mexico.

The people of Mexico, numbering in 1895 12,491,573, are over one-third Indians, embracing thirty-five tribes, living in communities in villages; the Mestizos, the half-breeds, with a mixture of Spanish and Indian blood, who form about one-half the population, and the higher class, which is largely Spanish. The republic to-day comprises 27 states, classified as inland states, and those adjacent to the Atlantic, and to the Pacific, besides the federal district, and two territories. The farm laborers are drawn mainly from the native Indians, who are scarcely less slaves than were their ancestors under the Spaniards. Their food is largely corn, usually ground by the women in hand mills, and baked in thin cakes, called tortillas. The higher classes have all the luxuries of New York and Paris, so that one sees the same extremes in the people and in their habits as are found in the climate and products. Education is far behind the modern standard, only nine per cent. of the people knowing how to read or write. Free schools have been established, however, in most of the towns. The people are largely Roman Catholic, though there is now no state religion. In 1867, the convents and monasteries were abolished, and religious processions in the streets forbidden. Protestant missions have been established within the last few years.

The early history of Mexico, as learnt from its monuments and picture writings, includes two periods — that of the Toltecs, and the Aztecs. The Toltecs are thought to have reached the country about the 8th century; they cultivated the land, introduced corn and cotton, made roads, and built temples, cities, and monuments, whose ruins still prove their skill. To their invention is thought to belong the Mexican hieroglyphics, or system of writing by pictures, and the Mexican calendar. They are believed to have been driven south by famine and pestilence to Guatemala and Yucatan in the 11th century. After an interval, about the end of the 12th century, the Aztecs entered the land and founded, about 1325, the city of Mexico. They were a less cultivated race than the Toltecs, but more so than the North American tribes, though they are considered now as belonging to the same family. (See AZTECS.) The Spaniards under Cortez landed at Vera Cruz in 1519, and the story of the latter's conquest of Mexico is one of the romances of history. In 1540, all the American territory belonging to Spain, including Mexico, was united under the name of New Spain, and governed by viceroys appointed by the home government. The policy of the government, however, hindered the development of the country. Mexico was looked upon simply as a mine to be worked for the benefit of Spain. The natives were distributed as slaves on the plantations, and trade with any country but Spain was forbidden under penalty of death. It was, in spite of this policy, however, one of the richest and most prosperous of the Spanish colonies. After three centuries of submission, the spirit of discontent, which had been growing during the wars of Spain with France, under Napoleon, broke out in rebellion in 1810, under the leadership of a country priest, named Hidalgo. In 1821, the last of a series of fifty-seven Spanish viceroys, O'Donoju, surrendered the capital. General Iturbide was proclaimed emperor in 1822, but General Santa Anna raised the standard of the republic, and Iturbide was banished to Italy, and shot the next year when he attempted to return. From that time on the history of Mexico is one of civil war, until 1876. Fifty-two presidents or dictators, one emperor, and a regent, ruled the country in that time.

Texas secured its independence in 1836, and in 1845 became a part of the United States. The boundary line was unsettled and a dispute over a strip of land brought on war with the United States, with its battles of Monterey, Palo Alto, Cerro Gordo, Buena Vista, and Chapultepec, ending with the taking of the city of Mexico by the Americans under General Scott. Peace was concluded in 1848, Mexico ceding to the United States half a million square miles of her territory. In 1861, under the presidency of Juarez, the country was again involved in war with the allied troops of England, France, and Spain, partly as the result of some of the internal improvements made by Juarez, such as the separation of church and state and the confiscation of church property, and partly because of acts of injustice to foreigners during this period of disorder. The difficulties were regulated by a treaty, which the French commander, however, did not agree to. Spain and England withdrew their forces, but France declared war, and entered the city of Mexico in 1863. The crown was offered to the archduke Maximilian, of Austria, who was declared emperor. After the withdrawal of the French troops from the country, owing to the remonstrance of the United States government, the republican troops under Juarez defeated the army of the emperor, who was taken and shot, in 1867. Juarez remained president until his death, in 1872, when Tejada succeeded; and in 1876, after another revolution, Porfirio Diaz, one of the ablest of Mexican rulers, became president. He was re-elected in 1884, in 1888, and again in 1900. Mexico is now divided into twenty-seven states, a federal district, and two territories. The present area of the republic is 767,005 square miles. Besides the city of Mexico (the capital), the chief towns are Puebla, Guadalajara, San Luis Potosi, Leon, Monterey, etc. The government is modeled after that of the United States. About 9,027 miles of railroads have been built, and nearly 43,000 miles of telegraph lines. Mines are being worked, coal fields opened, agricultural colonies established

and the whole country, so long behind the rest of the North American continent, started on the road to prosperity. See *Study of Mexico*, by David A. Wells; *Mexico*, in "Story of the Nations" series; *Popular History of the Mexican People*, by Bancroft; *Conquest of Mexico*, by Prescott.

Mex'ico, Gulf of, a basin of the Atlantic ocean, shut in by the peninsula of Yucatan and Florida, lies south of the United States and east of Mexico. It covers 716,200 square miles — more than one-fifth of the area of the United States. It is 1,100 miles long, though Yucatan and Florida are within 500 miles of each other. The coasts are low and sandy, with few good harbors, the best being New Orleans, Pensacola, and Havana. The island of Cuba is in the middle of the entrance to the gulf, dividing it into two straits, that of Florida, which connects it with the Atlantic ocean, and the straits of Yucatan, opening into the Caribbean sea. The largest river flowing into it is the Mississippi. The gulf stream enters the gulf of Mexico by the Yucatan channel, flows round it and passes out by the Florida strait. The gulf is visited by severe winds, called northers. See GULF STREAM.

Meyerbeer (*mī'er-bār*), **Giacomo,** a musical composer, was born at Berlin, Prussia, Sept. 5, 1791. His name was Jakob Beer, to which he added the name Meyer, a benefactor of his, and gave the whole name an Italian form. At the age of seven he played Mozart's music on the piano in public. His earlier works were unsuccessful and he proceeded to Italy for further study. He got hold at once of Rossini's style, which was just then popular, and brought out three operas, for the last of which he was crowned with laurel on the stage at Venice in 1824. In 1831, he produced *Robert le Diable* (the devil) in an entirely new style, which cast even Rossini into the shade. After the success which followed the production of *The Huguenots* he was appointed chapel master at Berlin. His *Prophet* appeared in 1849. In the comic opera, to which he now turned his attention, he wrote *The Star of the North* and *Dinorah*. His last work, *L'Africaine*, was not made public until a year after his death. He published many miscellaneous compositions, a stabat, a Te Deum, some cantatas, and songs. His operas are still popular and are frequently produced, especially at the Paris Opera. He died at Paris, May 2, 1864.

Miami (*mī-am'i*), a river in the western part of Ohio, flows south for 150 miles and empties into the Ohio river, 20 miles west of Cincinnati. The Miami canal runs beside it for 70 miles, and together they furnish extensive water-power for manufactures. It is sometimes called the Great Miami, to distinguish it from the Little Miami, which runs for 100 miles in the same direction, and flows into the Ohio, six miles east of Cincinnati.

Miamis (*mī-ām'ēz*), an Indian tribe found in the 17th century by the French near Green bay, and on the Fox and St. Joseph's rivers. They were related to the Illinois tribe and belonged to the Algonquin family. In 1721, they were found on the Miami, the Wabash, and the Ohio. In the French and English wars they sided sometimes with one party and sometimes with the other, but during the Revolution went with the English. They were hostile to the settlers, and in 1790 General Harmar was sent against them. Under their chief, Little Turtle, they defeated General St. Clair, but after a defeat by Wayne they made peace in 1794. In 1809, they yielded their lands from the Wabash to the Ohio state line, and after another struggle with the United States troops again made peace with them in 1815. They gave up all their lands in 1838 and 1840, and were finally removed to Kansas in 1846, and from there, in 1873, to the Quapaw reservation in the Indian territory. They numbered when moved only 150, having dwindled to that from a tribe of 8,000 warriors.

Mi'ca, from a Latin word meaning "to glitter," is the name of a group of minerals which are noted as being easily divided into sheets. These sheets can be made so thin that it will take one thousand of them to make an inch in thickness. There are different varieties of mica, what is called the Muscovite being the most common form. It is formed largely of silica, alumina, and potash, and is called a potash mica. It is found in granite rocks, gneiss, and in layers with quartz, making what is called mica schist. Large plates of it are sometimes found, as in New Hampshire, and in Sweden and Norway. Mines of it have been discovered in North Carolina. Other varieties, having especial names, belong to classes called soda micas, lithia micas, magnesia micas, and iron micas, according to their composition. Mica is used in stoves and lanterns, because it is transparent and will bear heat. It is used in some countries for window-glass.

Mi'cah was one of the "minor prophets," a native of Gath, in the lowlands of Judæa. He prophesied during the reigns of Ahaz, Jotham, and Hezekiah, kings of Judæa, at the same time as Isaiah and Hosea and Amos, about 759–698 B. C. The work he undertook was to reform the people, and he does not spare priests, prophets, nobles, or people, in his charges of cruelty, oppression, greediness, and ungodliness. He foretold the destruction of Jerusalem and the temple a hundred years before Jeremiah.

Mi'chael An'gelo. See ANGELO.

Michel (*mē-shel'*), **Louise,** a French anarchist and communist, was born at Chateau-Vroncourt, France, in 1839. She was a writer of verse of some power. During the outbreak of communism in Paris, after the

Franco-Prussian war in 1870, she was one of the most active leaders. In 1871, she was sentenced to exile for life, and banished to New Caledonia. In 1880, a general pardon having released her, she returned to Paris and became the editor of *The Social Revolution*. Of recent years she has resided in London, where she published her *Memoirs*, and a novel entitled *The Microbes of Society*.

Michelet (*mē-shlā'*), **Jules,** a great French historian, was born at Paris, Aug. 21, 1798. At twenty-three he became a professor of history in the College Rollin; he lectured at other colleges; became an assistant to Guizot at the Sorbonne, and in 1838 professor of history at the College of France. He wrote first small books on French and modern history, and began his great work, *The History of France*. His quarrels with the Jesuits resulted in three books directed against them. His famous *History of the Revolution*, in seven volumes, was begun in 1847. It is not considered a reliable history, though very readable. He lost his position by refusing to take the oath of allegiance to Napoleon III., and devoted himself entirely to literary work. He published a series of books on *Birds*, *Insects*, *The Sea*, and *The Mountains*, also *Woman* and *Love*. His great work, *The History of France*, begun in 1833, was finished in 1867, in eighteen volumes, and brings down the story of France to the revolution. His *History of the Revolution* carries it on to the close of that period. He began in the later years of his life a continuation, but did not live to complete it. His history is injured by his prejudices; but the characters stand out clearly, and there are passages almost unequaled in historical writings, such as his account of Joan of Arc, and of the Templars. Most of his works have been translated into English. He died at Hyères, in southern France, Feb. 9, 1874.

Mi'chelson, Albert Abraham, a brilliant physicist born at Strelno, Poland, Dec. 19, 1852; graduated from the United States Naval academy in 1873; resigned from the navy in 1881 to accept a professorship in physics at the Case School of Applied Science. When Clark university was founded, he resigned at Cleveland to accept a similar appointment at the new institution. Since 1893, he has been head-professor of physics at the University of Chicago.

His earliest important work was an improvement in Foucault's method of measuring the speed of light. These researches were carried out at the Naval Academy in 1878–80. His various memoirs on the interference of light waves, on the relative motion of the earth and the ether, on the length of the standard meter in terms of the wave-length of codmium light, and on the new echelon spectroscope are so important as to have already become classical. Besides his scientific attainments, Professor Michelson is a man of very varied accomplishments, and, naturally, the recipient of many honors from various universities and societies.

Mich'igan, one of the western states of the Union, is made up of two peninsulas, separated by the Straits of Mackinac. The lower peninsula is the larger and lies between Lake Huron, Lake Michigan, and Lake Erie, and the upper one lies between the lakes Huron, Michigan, and Superior. Its land surface covers, approximately, 57,430 square miles, and is larger than England and Wales; it is about 500 miles long. A considerable part of the state is water, there being besides the Great Lakes on its borders, over 5,000 small lakes. It has a coast line of 1,624 miles, with 120 lighthouses and many fog-signals. The lakes have many islands; the Manitoulin Island in Lake Huron, among the largest, covers 1,000 square miles. Lake Huron alone has 3,000 islands. The Straits of Mackinac, the passage between Lake Michigan and Lake Huron, are only four miles wide. Several large bays are on the coast,—Saginaw Bay on the east, and Great and Little Traverse on the west. The passage from Lake Erie to Lake Huron is through the Detroit river, Lake St. Clair, and the St. Clair river, the Detroit river being 20 miles and the St. Clair river 40 miles in length. The Lake St. Clair canal, called the Cut, was built in 1871, and is 8,200 feet in length, and is used by over 2,500 ships yearly. The St. Mary's ship canal, at the head of the St. Mary's river, has the largest lock in the world, and more ships pass through it than through the Suez canal. The largest rivers are the Grand, 270 miles, Saginaw, Au Sable, Kalamazoo, and St. Joseph. The upper peninsula has the highest land in the state, the Porcupine mountains, and the Mineral Range a little farther south. The climate is warmer than that of the same latitude in Wisconsin, and its fruits and flowers more varied. Michigan has large salt wells, the product being already greater than that of New York. Coal, though not of the best quality, is found; grindstone quarries are in operation, while large amounts of fire clay are used in the manufacture of drain pipes, etc. Marble, freestone, limestone, and glass sand, with copper and iron, also form the mineral wealth of the state, besides its many mineral springs. The iron ore is the purest in America, and amounts to one-fifth of the whole product in the United States, and is found mostly in the northern peninsula. The richest copper mines in the world are found near Lake Superior, at Keweenaw Point, and gold mines are in operation near Ishpeming. The soil is a light, sandy loam, barren in the north, but rich and fertile in the south, and the state is one of the best fruit states in the Union. The lumber business is the chief industry of the state, besides the production of iron ore, Michigan standing first in the value of its lumber. The forests of the

northern part are almost inexhaustible and keep at work 1,000 mills. Among the manufactories of Michigan are many depending upon the large supply of lumber, such as wooden bowls, windmills, broom handles, pumps, wheelbarrows, wood pulp, veneers, carpet sweepers, beehives, and toys. Shipbuilding is carried on largely, and the making of cars of all sorts and snow-plows for the use of railroads. Other industries are connected with the beet-sugar production, with that of fermented liquors, and with the manufacture of tobacco and cigars. There are also considerable activities in the state in the operations of creameries and cheese factories.

The University of Michigan at Ann Arbor, one of the largest institutions in the country, was one of the earliest and most successful of the state universities. The Agricultural college of the state is at Lansing, the Mining school at Houghton, and there are colleges at Kalamazoo, Adrian, Albion, Battle Creek, Hillsdale, Detroit, Olivet, and Holland. Fort Wayne, near Detroit, commands the river and has a small garrison. Michigan has done and is doing considerable for elementary as well as for higher education. Besides her nine colleges and universities for both sexes and her professional schools, she maintains nearly 8,000 schoolhouses and a staff of 15,560 teachers.

Michigan was first visited by French Jesuits and a mission established for the Chippewas in 1641, and in 1688 Father Marquette renewed the mission and later formed another at St. Ignace for the Hurons, which soon became a French fort. Other settlements were made by La Salle, Duluth, and Cadillac. In 1760, there were British garrisons at Detroit and other points, many of them being destroyed by the Indians under Pontiac. Detroit was the capital of the British possessions in the northwest until 1796. In the War of 1812 it was taken by the English and retaken by Commodore Perry. Michigan was admitted to the Union in 1837. The capital is Lansing (population 16,485), though the chief city is Detroit (population 285,704). The population, 2,420,982, includes 6,000 Indians and a large number of Canadians. See *Michigan*, by Cooley.

Mich'igan City, a town in Laporte county, Ind., on Lake Michigan, and its only lakeport, 38 miles east of Chicago. It has a good harbor, and manufactures cars, refrigerators, boots, and furniture. It contains a college and state prison and car shops. Population 14,850.

Mich'igan Lake, the third in size of the five great fresh-water lakes of America, and the only one lying entirely within the United States. It separates the states of Illinois and Wisconsin from Michigan, the upper portion of the lake dividing the state of Michigan into two parts. It is 338 miles long and from 50 to 88 broad, and covers 22,450 square miles. Its shores are low, with several lighthouses, and good harbors at Chicago, Milwaukee, and Racine.

Micklewicz (*mits-kyā'vitch*), **Adam.** See LITERATURE.

Micrometer (*mi-krŏm'ē-tĕr*), an instrument for measuring the dimensions of very small objects. The object measured is nearly always the image produced by a microscope or by a telescope. From the size of the image the angular or linear size of the object may be inferred when the focal lengths of the lenses are known.

Practically all micrometers are based upon the principle of the screw. In the focal plane of the instrument is fixed one line, usually a spider web. On a small metallic frame is mounted another spider web. This metallic frame is the nut of a screw with a fine thread and a divided head. By moving the instrument or the object, one side of the object is made to coincide with the fixed thread and the other side of the object with the movable thread. The number of revolutions of the screw required to carry the movable thread from this position to one of coincidence with the fixed thread is the size of the object in terms of the screw. The angular distance between two stars can thus be measured with the greatest accuracy; while with a microscope objects even smaller than $\frac{1}{100000}$ part of an inch have been measured.

Microphone (*mī'krō-fōn*), an instrument in which sound waves are employed to produce variations of electrical resistance, and hence transmit electrical effects to a considerable distance. The principle upon which the instrument rests is the fact that the electrical resistance of carbon varies with pressure to which the carbon and its connections are subjected. One of the earliest forms of microphones was that devised by Hughes in England in 1878, which consisted essentially of a small rod of gas carbon, standing upright with its lower end on a carbon button and with its upper end held in a carbon collar. These three carbons, resting upon a resonance box, formed a part of an electric circuit, which included also a telephone. This instrument is so sensitive that the tread of a fly can be heard at a long distance.

The modern telephone transmitter is essentially a microphone, in which the pulsations of the air due to the human voice alternately increase and diminish the pressure at one of the contacts in the telephone circuit. See TELEPHONE.

Micropyle (*mī'cro-pīl*) (in plants), the small opening left by the integument or integuments of an ovule, through which the pollen tube ordinarily passes to the nucellus. When the seed ripens, the micropyle is usually left as the weakest spot in the seed coat, and through it the embryo first protrudes. See OVULE.

Mi'croscope, a magnifying instrument. The simple microscope consists of a single convex lens or set of lenses by which the object is viewed directly. The compound microscope is a combination of lenses, one set — the objective — placed near the object forms a real image, and this is further enlarged by a magnifying eyepiece placed next to the eye of the observer. The date of the invention of the microscope is uncertain. It is known that Roger Bacon, in 1276, used a lens of rock crystal for magnifying objects, and he is generally regarded as the inventor of the simple microscope. The weight of evidence seems to point to Galileo as the inventor of the compound microscope in 1610. Those ascribed to the Janssens in 1590 were simple microscopes. Simple microscopes were brought into general use by Leeuwenhoek (1632–1723) and by Malpighi (1628–94) in the 17th century. The former had a collection of more than four hundred lenses, magnifying from forty to two hundred and seventy diameters, and he was the father of microscopic observation. From that time to the present the microscope has been greatly in use. At first, it was the newness and the wonders of the microscopic world that made the attraction, but gradually it came to be used as a tool or implement of study. In 1840, the manufacture of lenses or magnifying glasses was vastly improved, and, ever since, the microscope has been used in research to serious purpose. It has been the means of showing the minute structure of all tissues, the protoplasm upon which their activity depends, their condition in health and disease. It has shown the germs of disease, it has made possible an analysis of the sense-organs, and has helped greatly in the comprehension of all nature. Many brilliant and important discoveries have been reached through its use. See BACTERIA, CELL DOCTRINE, DEVELOPMENT, PROTOPLASM.

The compound microscope consists of mechanical parts and optical parts. The mechanical parts taken together constitute the stand (see illustration). This has a base, or foot, from which rises a supporting pillar carrying a stage and an arm. The stage is for holding objects to be examined; it is perforated by a round aperture, through which light is thrown from a mirror located underneath the stage. The size of the aperture is usually regulated by an iris diaphragm, and often there is a glass condenser for the light. The arm carries a tube in which the lenses are inserted. Finally, there is a means of bringing the lenses into focus. This is accomplished by a coarse adjustment — usually a rack and pinion movement — to move the tube quickly into position, and a fine adjustment, for slow movements, to get an accurate focus. The latter is very important in using lenses of high magnifying power. It is usually a micrometer screw and spiral spring. A good stand should be firm, low enough to work upright in order to avoid currents in fluids, which occur when it is tilted, and should have a good fine adjustment. The lenses, or optical parts, are the most important parts of a microscope. Those which do the greatest amount of magnifying are attached to the tube, near the object, and called objectives. The oculars, or eyepieces, fit in the tube near the eye of the observer. The degree of magnifying power depends on the lenses used. The ordinary working powers range from seventy-five to five hundred diameters. When a higher degree of magnification is desired, it is not necessary to purchase a new microscope, but simply to get a new objective. The cost of objectives of high magnifying power is considerable, and the difficulty of working with those magnifying above six hundred diameters is also considerable. Student's microscopes can be obtained from $15 upward; a good one will cost $40 and upward. There are many good makers of microscopes, but those most highly esteemed at the present time are made by Bausch and Lomb, of this country, Leitz, of Westlar, and Zeiss, of Jena, Germany. Microscopic technique has become an art and a science, and on it much of success in discovery depends. See Carpenter's *The Microscope and Its Revelations* (7th edition, 1891), and Beale's *How to Work with the Microscope.*

MICROSCOPE.

Microsporangium (*mī'kro-spo-răn'gĕ-ŭm*) (in plants), the sporangium which produces microspores. In pteridophytes they are produced by the water ferns, selaginella, and isoetes; while in all seed-plants (spermatophytes) the so-called pollen-sacs are microsporangia. See HETEROSPORY.

Microspore (*mī'krō-spōr*) (in plants). In cases of heterospory (which see) the small asexual spores are called microspores. In germination a microspore produces a male gametophyte, that is, one which bears the sperms. Microspores are found in a few pteridophytes and in all spermatophytes. In

the latter group the microspores are better known as pollen-grains. See HETEROSPORY.

Microsporophyll (*mī'kro-spo'ro-fil*) (in plants), the sporophyll which bears microsporangia. They are chiefly developed in seed-plants, where they are usually called "stamens." See HETEROSPORY.

Midas (*mī'das*), one of the ancient kings of Phrygia, who are always called either Midas or Gordius. According to mythology, Midas, for a kind act, was promised by Dionysius whatever he should ask. He, believing gold to be the best possible thing, asked that everything he touched should turn to gold; but when the request was granted, he found to his sorrow that there are many things more necessary, for even his food became gold, and, in danger of starving, he begged the god to take back the gift. He was sent to wash in the river Pactolus, the sands of which still yield grains of gold. He decided a contest between Pan and Apollo in favor of Pan, and Apollo in revenge gave him a pair of ass's ears, which he hid under a cap. The secret so oppressed his barber that he dug a hole in the ground and whispered into it, "King Midas has ass's ears." The reed is said to have grown from this hole, and is thought to whisper the secret whenever stirred by the breeze.

Mid'dle Ages, also called mediæval, is the period between ancient and modern times in history. It is generally thought to begin in 476, after the downfall of the western empire of Rome, and to end with the reformation in the first part of the 16th century, or a little earlier, in the latter part of the 15th century, when America was discovered, printing invented, and the new impulse given to learning by Greek refugees from Constantinople. The term, "Dark Ages," is used to cover about the same period, and indicates the time in history when learning was at its lowest stage, between the era of the classical literature of Greece and Rome, and the literature of modern Europe.

Mid'dlebury, a town in Vermont, 33 miles southwest of Montpelier. The region is picturesque, with views of the Green mountains and near-by Lake Dunmore, five miles long, nestled among the hills. A fine variety of marble is quarried here, and there are several manufacturing establishments. It is the site of Middlebury college, founded in 1800, and having at present eleven professors. Population 1,897.

Middlesbrough (*mid'dlz-b'rŭh*), a manufacturing town of Yorkshire, England, near the mouth of the river Tees. In 1829, there was only a single farmhouse, surrounded by marshes, on the site of the town. Its growth is due to the discovery of iron ore in the Cleveland hills near by. One-third of the great iron production of the United Kingdom is from the Cleveland mines. The industries of the city are iron and steel works, blast furnaces, sawmills, shipbuilding, wire, nail and tube works, and large salt and soda works. It has fine public buildings and large parks. In 1899, the total tonnage entered and cleared, excluding the merely coastwise tonnage of Middlesbro', was next to that of Swansea — viz., 2,100,000 tons. Population 80,000.

Mid'dletown, N. Y., a town in Orange county, southeastern New York state, 24 miles west of Newburg, and 65 miles northwest of New York city. It is an agricultural and pastoral region, and is served by the Erie, the New York, Ontario and Western, and the New York, Susquehanna, and Western railroads. Here is the New York Homeopathic hospital for the insane. It is well supplied with schools, churches, libraries, banks, etc., and its industries embrace woolen-hat factories, silk and handkerchief mills, and saw and file works. Population 14,522.

Mid'ianites, an Arab race, inhabiting the country between the Red sea and the plains of Moab, near the Dead sea. Their caravans traveled from Egypt to Syria, carrying gold and incense to Palestine. Jethro, the father-in-law of Moses, was either a priest or a chief of the Midianites. They were troublesome neighbors to the Israelites until conquered by Gideon. They worshiped Baal-Peor. In the times of the Romans there were valuable mines in Midian, and petroleum is found there. The country became a Turkish possession in 1887.

Mid'rib (in plants). In case there is one central main rib in a leaf, this is spoken of as the midrib. It is found in leaves of the pinnate type of venation. See LEAF.

Mignonette (*min'yŭn-ĕt'*), a plant cultivated for its fragrance, and a native of North Africa. The name means "little darling." It has long clusters of small greenish-yellow or white blossoms, and is cultivated by florists for bouquets on account of its well-known delicious odor.

Milan (*mil'an* or *me-lan'*), a city in Italy, the third in size, ranking next to Rome and Naples. It stands in the great Lombard plain, 25 miles south of Lake Como, at the foot of the Alps. Surrounded on three sides by walls, it is entered by fourteen gates. Though an old city, it has been ravaged by war so often as to have few ancient buildings. The modern city has broad, regular streets, fine buildings, and attractive promenades. The cathedral, on the site of two more ancient ones, begun in 1386, was finished, by order of Napoleon, in 1805–13. There are 6,000 statues in niches on the outside, and a great number of pinnacles. The church of St. Ambrose (868), St. George (750), and St. Maria (1463), with Leonardo da Vinci's famous painting, *The Last Supper*, on its walls, are other ancient churches. The palace of arts and sciences

has a valuable collection of paintings by Raphael, Titian, Vandyck, Mantegna, and others. The national library has nearly 200,000 volumes, with a museum and an observatory, and the Ambrosian library, 175,000 volumes, and a fine collection of paintings and engravings. There are numerous palaces, an arch of peace, built of white marble, in memory of Napoleon, the arcade of Victor Emmanuel, used as a promenade, an arena for shows and races, holding 30,000 people, and the great hospital for 2,500 patients. The city has an extensive trade in silk, cotton, grain, rice, and cheese, and manufactures silks, velvets, gold, silver, and iron wares, railroad cars, tobacco, and porcelain. It is also a center of the printing trade, and the chief banking city of northern Italy. Population 492,162. Historically, it was a town of the Gauls, was conquered by the Romans in 222 B. C., and became a rich and important city. In the 4th century, it was the court city. The Huns, the Goths, the Longobards, and the Franks held it at different periods until it was subjected to the German empire in 774; and several of Charlemagne's successors were crowned at Milan. In the 11th century, as the head of the Lombard league, Frederick I. twice besieged it, and once almost destroyed it. In 1395, the Ghibellines made Milan the capital of a duchy, which extended over the whole of Lombardy, Matteo Visconti being the first duke. From 1450 to 1535 his successors, the Sforzas, ruled the country. It passed then to Spain; from Spain to Austria, and from Austria to Napoleon, who made it the capital of Italy. It belonged again to Austria until the peace of Villafranca (1859), when it was ceded to France, and yielded by France to Sardinia.

Mil'burn, William Henry, known as the "blind preacher," was born at Philadelphia, Sept. 26, 1823. He was a Methodist clergyman and traveled over 200,000 miles in his circuits. In 1856, he was chaplain of the house of representatives at Washington, a position he filled for many years, being re-elected at different periods. He wrote a number of books, *Rifle, Axe, and Saddlebags*, *Ten Years of Preacher-Life*, and *Pioneer Preachers of the Mississippi Valley*, being among them. He died in 1901.

Mil'dew, the name of various plants (fungi), but chiefly applied to a large group of the ascomycetes (which see), which are external parasites growing chiefly upon the leaves of seed-plants and covering the surface like a delicate cobweb. The mildew on lilac leaves is one of the most common forms, this host plant being very seldom free from it. The "downy mildews" belong to the phycomycetes (which see), and are destructive internal parasites. One of the commonest forms attack grape leaves, making its presence known by small downy patches which come to the surface and consist of minute branches bearing spores.

Miles, Nelson A., an American general, was born at Westminster, Mass., Aug. 8, 1839. At the outbreak of the Civil war he entered the 22d Massachusetts volunteers as lieutenant. He was in every battle of the army of the Potomac, with one exception (and was then absent on account of desperate wounds); distinguished himself at the battles of Fair Oaks, Fredericksburg, Chancellorsville, Malvern Hill, Spottsylvania, Richmond, and many others; was thrice wounded, and at Chancellorsville was carried from the field with what was then supposed to be a mortal wound. His bravery and abilities won for him promotion after promotion until he became a major-general and was placed in command of a division. When the volunteer army was disbanded, in September, 1866, he was commissioned colonel of the 40th United States infantry. In March, 1869, he was transferred to the 5th infantry. Since then, his promotion has been rapid, having been made brigadier-general in 1880, and major-general in 1890.

GEN. NELSON A. MILES.

Since the close of the Civil war, General Miles has earned fame as an Indian fighter. He conquered the hostile Sioux in Montana, and drove Sitting Bull, their leader, into Canada in 1876, after the massacre of General Custer and his force. In 1877, General Howard having pursued the Nez Perces for 1900 miles and arranged for their surrender, designated General Miles to receive the surrender of Chief Joseph. The next year General Miles captured the Bannocks near Yellowstone Park. He served from 1880 to 1885 in the department of the Columbia, and was then transferred to the department of the Missouri, and the next year to Arizona, where he compelled the Apache chiefs Geronimo and Natchez to surrender. In 1890, during the "ghost dance" outbreak among the Sioux, General Miles had command and forced a surrender in January, 1891, at Wounded Knee, South Dakota. On the retirement of General Schofield in 1895, General Miles succeeded to the command of the United States army. In the Spanish-American war, he was at the head of an expedition to Porto Rico, effecting a landing at Guanico, July 25, 1898. He has published *Personal Recollections*, and a work entitled *Military Europe*. He was promoted to the rank of lieutenant-general in 1901.

Miletus (*mi-lē'tus*), an ancient city of Ionia, in Asia Minor, near the river Meander. It was famous for its woolen cloth and carpets and furniture, and had a very large trade. Nearly eighty colonies were founded by its citizens on the Black sea and in the Crimea. They sent their fleets to all parts of the sea, and kept up a long war with the kings of Lydia until conquered by Crœsus. Under the elder Cyrus the city was conquered by Persia, and again, after a rebellion, was taken by Darius and nearly destroyed. Although rebuilt and sufficiently powerful to contend with Alexander, who took it by storm, it never regained its importance, and was finally ruined by the Turks.

Milk, the well-known white fluid obtained from the cow, though the milk of goats and asses has been made use of. It is one of the most important foods we have, as it contains all the elements needed for the body, and is easily digested. When examined by a microscope it is seen to consist of a large number of round substances, or globules, which are transparent and very small, and float in a colorless fluid. These globules are made of fat, with a thin coating somewhat like the white of an egg, called casein. When the milk stands, the larger globules rise to the top and make the cream, which is the fattest or richest part of the milk. When the cream is shaken, as in a churn, these globules break, and the fat runs together, making lumps, which is called butter. The casein which surrounds the globules of fat, and which is also dissolved in the liquid, if it becomes sour, either naturally, by exposure to the air, or by the addition of rennet, or an acid of any kind, collects into masses called curd. This change is brought about partly by minute forms of animal life, called microbes, which get into the milk from the air, and this is one reason why it is so necessary to purify by heat, usually hot water, all the articles used about milk. These clots or curds, made by the addition of rennet to the milk, are pressed into blocks and make cheese, which is a very rich food, containing all the fat of the milk, as do cream and butter, and besides the casein, which is an albuminous substance. Condensed milk is prepared by sweetening the milk, and evaporating it until it loses about one-half or three-fourths of its bulk. It is poured into tins while hot, and sealed. When used it is diluted with several times the quantity of water. The adulteration of milk by adding water, starch, or chalk, is frequent in large cities, and has called for boards of inspectors, and produced instruments, known as lactometers, for detecting it. The most common fraud, however, in the sale of milk is removing the cream. The supplying of a large city with cream and milk creates a great business, and employs many men: those who milk the cows at all hours of day or night; the railroad employees who run the great milk trains; the large dealers who distribute it to the wagons; and the drivers of the milk-carts whose noisy clatter disturbs the early morning nap, but whose faithful labors in heat or cold furnish the milk and cream for our breakfast.

Milk'weed, species of Asclepias, a genus of the milkweed family, which contains about 85 species, mostly natives of the western hemisphere, nearly 50 of these species occuring in North America. The name comes from the fact that they contain a milky juice which exudes from wounds. They are also often called "silkweeds" from the fact that the large pods contain numerous seeds bearing beautiful tufts of silky hair. One of the most attractive forms is the "butterfly-weed" or "pleurisy-root" (*A. tuberosa*), whose flowers are bright orange. The other forms are taller and have chiefly purplish to red flowers, occasionally white. The flowers are all very much modified for insect pollination, the pollen grains clinging together in masses which are carried off by the insects bodily. Probably the commonest known milkweed is *A. cornuti*, also known as *A. syriaca*. The weed grows in fields and moist places everywhere, and has a stout tall stem and broad opposite leaves.

Milky Way, a band of faint light which stretches across the sky from horizon to horizon. The light is produced by a multitude of stars so distant or so small that they can be distinguished only by the telescope. It is brighter in the southern sky than in the northern. In one part of its course it divides into two branches.

Most of the stars in the milky way are of less than eighth magnitude. Among them are many star clusters, but very few nebulæ. This feature of the heavens is frequently called the *Galaxy*, which is merely the Greek word for *Milky Way*.

Herschel, who was a profound student of this subject, suggested that the galaxy is a natural plane of reference for the stellar universe, just as the ecliptic is a natural plane of reference for the solar system.

Mill, John Stuart, the son of James Mill, who was also known as a writer and utilitarian philosopher, was born at London, May 20, 1806. His early education was carried on by his father, beginning with the study of Greek when three years old, and making him at fourteen as advanced as most young men at the end of their period of study. But as he says himself, he was "never a boy." His recreation was in the form of long walks with his father, where the process of education was carefully carried on by questions and answers. His first writings appeared in a newspaper in 1822. In the same year he received an appointment in the India office, which he held until the East India company transferred its power to the crown, leaving its employ as the head of a department. Before he was

twenty, he was recognized as a leader in philosophy and politics, and was the most frequent contributor to the *Westminster Review*—a magazine which represented the ideas of his party. He somewhat changed his philosophical theories later, under the influence of Maurice, Sterling, and Coleridge. His most important works are his *System of Logic*, *Principles of Political Economy*, *Auguste Comte and Positivism*, *Considerations on Representative Government*, *Dissertations and Discussions*, *England and Ireland*, and *On Liberty*. He was radical in politics, and very much in favor of woman's suffrage, leading in the movement in England to give women legal and political rights. He died at Avignon, France, May 8, 1873. See his *Autobiography*, which appeared in the year of his death; also *Life*, by Bain; *Life and Works*, by Herbert Spencer, Thornton, Fox Bourne, and others.

Millais (*mil-lā'*), **Sir John Everett,** an English painter, was born at Southampton, England, June 8, 1829. His *Pizarro seizing the Inca of Peru* was shown by him at the Royal academy when only seventeen and was considered equal to the best historical paintings then exhibited. He became connected with Rossetti and Hunt, and was much influenced by them, as well as by the writings of Ruskin on art. Pictures of this period of his life are *Christ in the House of His Parents*, called *The Carpenter's Shop*, *The Woodman's Daughter*, and *The Huguenot*. After his election, in 1856, to the Royal academy, he exhibited *Autumn Leaves;* later he finished the *Vale of Rest*, *The Minuet*, and *Rosalind and Celia*. His later works show another change in his ideas of art, and in their brilliant coloring and high finish are almost unrivaled in modern work. The *Boyhood of Raleigh*, *The Gambler's Wife*, *The Proscribed Royalist*, *Yeoman of the Guard*, *Yes or No*, *The Order of Release*, *The Black Brunswicker*, and *Effie Deans*, are among his later paintings. His illustrations published in *Good Words*, *Once a Week*, and the *Cornhill Magazine*, placed him in the first rank of wood-cut designers. A collection of nearly twenty of his pictures was brought together in 1881 by the Fine Arts society of London, and 159 of them were exhibited at the Grosvenor gallery in 1889. He died at London, Aug. 13, 1896.

Miller, Hugh, a Scotch geologist and writer, was born at Cromarty, in north Scotland, Oct. 10, 1802. His education was gained mostly by reading in the intervals of his work as a stonemason. In 1829, his *Poems written in the Leisure Hours of a Journeyman Mason* appeared, and in 1835 *Scenes and Legends of the North of Scotland*. His famous *Letter to Lord Brougham*, in the church disputes in Scotland, brought him into notice, and he was invited to Edinburgh to edit a Liberal and Presbyterian newspaper, *The Witness*. A series of geological articles in this paper, when published in book form, was called *The Old Red Sandstone*, and contained an account of his discovery of fossils where they had never been thought to exist. His work brought him the notice of Murchison and other great geologists, Agassiz saying "he would give his left hand to possess such powers of description." He contributed at least one thousand articles to *The Witness*, and also contributed to *Chambers' Journal*. He wrote also *Footsteps of the Creator*, *My Schools and Schoolmasters*, *Testimony of the Rocks*, and *Cruise of the Betsey*. He was one of the first writers to make geology popular, and his books are very readable to those not particularly interested in that science. He died at Portobello, near Edinburgh, Dec. 24, 1856, having shot himself in a fit of insanity. See *Life*, by Peter Bayne.

Miller, Joaquin, the pen name of an American poet, named Cincinnatus Heine Miller, born in Indiana in 1841. His early life was spent in Oregon and California, and among the Indians. He wrote verses in these early days, though with very little knowledge even of the rules of grammar. He studied law, and began practice in Oregon, where he wrote his poems, published first in London, *Songs of the Sierras*. He has since written *Songs of the Sunland*, *Ships in the Desert*, *Songs of the Mexican Seas*, *Songs of Italy*, and *Building of the City Beautiful*. He is a well-known contributor to newspapers and periodicals. Since 1887 he has made his home in California.

Millet, a name applied to several important grasses. The original millet or "broom-corn millet" of Europe is *Panicum miliaceum*. In the United States the common millets are forms of *Setaria italica* known as the "foxtail millets"; while the well-known "millet-grass" is *Milium effusum*. To the common brown millet (*P. crus-galli*) the name "Japanese millet" is sometimes given.

Millet (*mil'let*), **F. Davis,** an American traveler and artist, was born at Mattapoisett, Mass., in 1846. He graduated at Harvard in 1869, and for some time afterward was connected with one of the Boston journals. He then went abroad, studying art in Antwerp and Paris. Upon his return to America he was associated with John La Farge and Francis Lathrop in the interior decoration of Trinity church. In 1878, he went to the front in the Russo-Turkish war and served as war correspondent of *The London Graphic* in the Balkans (1878). He designed the costumes for the Greek play at Harvard in 1880. His later work has been done in studios at New York or at London.

Millet (*mē-lā'*), **Jean Francois,** a French painter, was born in the village of Gruchy, France, Oct. 4, 1814. The son of a farmer,

he at first worked as a farm laborer, but his taste for painting was so evident that he was sent to study with Monchel, a painter in Cherbourg. His master induced the town authorities to grant his pupil an annuity to help him in his studies. He went afterward to Paris and studied with Delaroche. He painted small pictures, portraits, and signboards in his first efforts to support himself. After the revolution of 1848, through which he had struggled practicing his art, and fighting at the barricades, he settled in Barbizon, near the Forest of Fontainebleau. He lived here much like the peasants and began his work of painting the peasant life of France. *The Sower*, *Peasants Grafting*, *The Gleaners*, *Waiting*, *The Angelus*, *The Man with the Hoe*, *Wool-Carding*, and *Shepherdess and Flock*, are some of his best-known works. His most celebrated picture, *The Angelus*, sold for over $100,000. It was exhibited for a year in the United States. He died at Barbizon, which under his influence had become an artist colony, Jan. 20, 1875. See *The Barbizon School*, by Millet.

Mill'ville, N. J., a town in Cumberland county, on the Maurice river, connected by electric railway with Bridgeton, in southern New Jersey, forty miles southeast of Philadelphia. It is served by the West Jersey railroad; north of the city is an extensive public park and fine sheet of water — Union lake. It possesses a number of churches, schools, banks, etc., and has several industries, including cotton mills, and iron and glass factories. Population 10,583.

Mil'man, Henry Hart, an English divine, historian, and poet, and dean of St. Paul's, London, was born at London, Feb. 10, 1791, and died near Ascot, Sept. 24, 1868. He was educated at Eton and Oxford, and in 1812 won the Newdigate prize with a poem on the "Apollo Belvedere." Early in his career he published a number of poems of much merit, several of which were in Latin, and in 1821 was elected professor of poetry at Oxford. His published writings embrace, besides his verse, a *History of Christianity*, a *History of Latin Christianity*, a *History of the Jews*, *Lives of Horace* and *Edward Gibbon*, the historian, a volume of *Bampton Lectures*, etc. He was at one time canon of Westminster, rector of St. Margaret's, London, and finally dean of St. Paul's.

Mil'ner, Alfred, Lord, G.C.M.G., British Governor of Cape Colony, and since 1897 High Commissioner of South Africa, was born in 1854 and educated in Germany, at King's college, London, and Balliol college, Oxford. Early in life he studied law and became a barrister, but, turning to journalism, was for a time a writer on the staff of the London *Pall Mall Gazette*. In 1885, he became private secretary to the Hon. Geo. J. Goschen, then British chancellor of the exchequer, and from 1888 to 1892 he acted as under-secretary for finance in Egypt, an experience as a resident of the country which enabled him to write *England in Egypt*, published in 1892. In the latter year he returned to England and served five years as chairman of the government board of inland revenue, when he was appointed governor of the Cape and chief commissioner of Great Britain in the negotiations at Bloemfontein, in May, 1899, preceding the Boer war. He is a man of acknowledged ability and tact, and, during a visit to England, in 1901, was made a Peer.

Milo (*mī'lō*), a Grecian athlete, born the latter part of the 6th century, was celebrated for his great strength. He was six times a victor in wrestling in the Olympic games and as often in the Pythian. He is said to have carried a live ox on his shoulder four times around the race-course of the Olympic games and then to have eaten the whole animal in one day. When Pythagoras and his scholars found the house in which they were gathered falling, Milo held it up on his shoulders while they escaped. But in his old age his strength proved his ruin, for in trying to split open a tree with his hands he was caught and held fast until devoured by wolves.

Miltiades (*mil-tī'a-dēz*), an Athenian general, who lived in the early part of the 5th century B. C. He was ruler in Chersonesus and took part against the Scythians, and was one of the ten generals chosen to resist the Persian invasion of Attica. When the generals were hesitating whether to risk a battle immediately or defend their country behind the city walls, through his influence the vote was in favor of a battle at once. When his turn came to command, he engaged the enemy and won the famous battle of Marathon. He was given command of a fleet of seventy vessels, and made an attack on the island of Paros, but failed in the attempt. He was condemned to pay a heavy fine and was thrown into prison because he was unable to pay it. He died in prison (about 489 B. C.) of a wound he had received at Paros.

Mil'ton, John, one of the greatest of English poets, ranking next to Shakespeare, was born at Cheapside, London, Dec. 9, 1608. He studied under private tutors, and at Christ's college, Cambridge. When he had finished his studies, he was prevented from entering the church, the only profession he desired, by its disturbed condition at the time. He settled down at home to study with the distinct purpose of making himself a poet. He had already written *Hymn to the Nativity* and some Latin verse. He wrote at this period only four poems, *Comus*, *Lycidas*, in memory of a friend, *L'Allegro*, and *Il Penseroso*. In 1638, he visited Italy, and received much attention from the poets and literary men of that country. He hastened back to England at the news of hostilities between Charles I. and Scotland, and for a long period the poet gave way to the politician. His

prose works are largely made up of pamphlets, which appeared on subjects which were in

JOHN MILTON.

dispute either in church or state, such as five on church government, one on education, and two in defense of the execution of Charles I., one of them being his famous reply to Salmasius. His famous *Areopagitica*, written in favor of free speech, was called forth by a threat of prosecution for the publishing of his tracts on *Divorce*. These had been written in 1643, when his wife, after a few weeks of married life, had gone home, and refused to return to him. There is much evidence that the pair were little suited to each other, and that the austere life of the Puritan home proved very cheerless to the young girl brought up in gay royalist circles. She returned to him in 1645. Cromwell rewarded Milton for his political papers with the office of secretary of foreign tongues, where his duty was to carry on the foreign correspondence of the government in Latin, the language used by the commonwealth. He was better fitted for the position than anyone in England, and held it until the restoration of the monarchy. He lived in concealment after the accession of Charles II., until placed in safety by the act of indemnity. His eyesight failed him entirely in 1654, and all his later work was written by another hand, usually one of his three daughters, who also spent many hours in reading to him in Latin and Greek, neither of which languages they understood. After about twenty years of silence, the poet sent forth his great work, *Paradise Lost*, finished in 1663, and published in 1667. He received $25 for the copyright, with a promise of the same amount with the sale of the first 1,300 copies of each edition. He received the second and third payments, and in 1681 his widow yielded up her rights in the book for $40. Thirteen hundred copies were sold in twenty months, which, considering the age, and the lack of reviews and other modern means of making a book known, gives some idea of Milton's rank as a poet among his own people. *Paradise Regained* was written at the suggestion of a Quaker friend, who intimated that Satan was the main hero of *Paradise Lost*. *Samson Agonistes* is the poem of his old age. His home-life seems never to have been peaceful until his third marriage, when his daughters left his home, and his last years were passed in cheerful retirement, solaced with music and friends. His last work, a Latin *Treatise of Christian Doctrine*, came into the hands of a state officer, and was placed in the state-paper office, and was accidentally discovered in 1823, nearly 150 years after it was written. He died in London, Nov. 8, 1674, already acknowledged to be the first poet of his age and country. See *Life*, by Masson; Johnson's *Lives of the Poets;* Trent's *John Milton;* and *Life*, by Mark Pattison, in "Men of Letters" series.

Milwaukee (*mil-wâ'kē*), the largest city in Wisconsin, is situated on Lake Michigan, 85 miles north of Chicago. It is at the mouth of three rivers, which are navigable, and, with a canal, make some twenty-two miles of docks. Milwaukee bay is seven miles wide, and furnishes a good harbor. The bluffs are terraced and parked, and stand 80 feet above the water. The city is built largely of what is known as Milwaukee brick, which is cream-colored, and gives the city its name of the "Cream City." It is 6½ miles long, its extreme width 5¼ miles, and its area 23.1 square miles. There are 600 acres of public parks connected by boulevards, wide, shaded streets, good water works, and many fine public buildings. Among these are the Federal building, a public library, city hall, free art gallery, large hotels, and many churches, and near the city the national home for disabled soldiers, with 2,400 inmates. Milwaukee has a well-organized system of public schools: three high schools, and 55 schools of lower grade, with 875 teachers and an attendance of 41,500 pupils. There are 75 incorporated colleges, academies, and lower schools with an attendance of 23,420. It has a very complete system of water works, costing over $5,000,000, and 140 miles of electric street railway. Milwaukee is one of the foremost grain ports of the world, and its immense flour mills and grain elevators can fit out a commercial fleet. It has nearly four thousand manufacturing establishments, with 67,000 employes, making large quantities of leather and leather goods, iron, and brass products, engines and machinery. The capital invested in manufactures is $125,000,000, and the annual output $175,000,000. It has an enormous beer trade, the Pabst brewery being one of the largest in the world and filling over 1,000,000 barrels a year.

The city has a large German population, which is seen in the many foreign signs met with, and also in the high development of art and music in city circles. The town was settled in 1835, and became a city in 1846. It enjoys a steady and substantial growth, and its financial credit is of the highest. Population in 1900, 285,315.

Mim'icry, the imitative resemblance of one animal to another, or to some inanimate object for which it may be mistaken. This is also called protective resemblance, in-asmuch as animals escape notice through this form of imitation, and are protected from their enemies. A wide range of cases occur in nature. For example, certain insects resemble leaves, others twigs and knots. Animals of the desert have a color merging into their surroundings; many animals, like lizards, adapt their colors to their surroundings, and thereby escape observation. Color resemblance is also carried further. Certain butterflies and caterpillars are not eaten by birds on account of their unpleasant taste. The birds learn to distinguish them by their bright "warning" colors and to leave them alone. Other forms, without noxious taste, imitate these colors and escape. A harmless animal sometimes imitates a stinging or poisonous one and is shunned. The animals protected in these various ways are, as a rule, unconscious of their imitation. Protective mimicry may be an important factor in the preservation of species. See Poulton's *The Colors of Animals* (1893).

Mindanao (*mĕn-dä-nä'ō*), the most southeastern of the Philippine islands, next in size to the island of Luzon, containing, it is estimated, 37,000 square miles. The population of that portion under Spanish domination was given by the last census made under the Spaniards as a little over 200,000; but the natives claim a population of twice that number outside the boundaries reached by the Spanish authorities. The surface is broken into high mountains, reaching in the case of Apo, a volcano near the gulf of Davao, an altitude of over 10,000 feet. The wet and the dry seasons shift from the one side of the island to the other according to the direction of the prevailing winds. The island is densely wooded with timber of great value, and the tropical fauna is varied and abundant. The inhabitants are greatly divided in origin, temperament, and religion. The interior parts of Mindanao are held by wild tribes of Malayan race, or by the small, black Negritos with whom they have intermarried. The Jesuits, who knew most about the island before the American occupancy, divided the people into twenty-four distinct tribes, of whom seventeen were pagan, six Mohammedan (Moro), and the remainder Christian Viasayans, who came in from the north. The warlike Moros are most dreaded, and, living along the frequented coasts, have held command of all important points. The rivers of Mindanao are larger and longer than those of Luzon, the Butan practically traversing the whole island from south to north. The soil is productive beyond exaggeration. Gold is believed to exist in the mountains. The capital of the province is Zamboanga, large and clean, with a pier extending out into moderately deep water. This island was the first of the group to be discovered by Magellan in 1521.

Mindoro (*mĕn-dō'rō*), one of the Philippine islands, containing, it is estimated, about 4,500 square miles. It lies directly south of Manila bay, having for its capital Calapan, one hundred and twenty miles from Manila. It was formerly inhabited by the Tagalogs, but various expeditions of the Moros have greatly reduced the number of the native population. Others died from cholera and fever, some years ago, when an epidemic among their herds carried off all their buffaloes and rendered cultivation of the soil no longer possible. The once rich rice fields have for the most part gone back to the condition of a tropical wilderness. In the interior of the island are mountains attaining a height of 8,000 feet. The native races still in these mountain fastnesses are greatly distrusted by those nearer the coasts. The population is supposed to be in the neighborhood of 15,000; but dread of the Sulus has kept the native races so far from the sea that but little is really known about them.

Min'eral Oil. See PETRO'LEUM.

Mineral'ogy, the science which treats of minerals, does not embrace all that relates to the mineral kingdom. Simple minerals alone are regarded as the subjects of mineralogy; rocks, formed by the aggregation of simple minerals, and their relations to each other are the subjects of petrology (the science of rocks) and geology. Mineralogy considers the composition, structure, formation, and classification of minerals.

PHYSICAL MINERALOGY embraces the outside form (generally shown by crystallization) of minerals and the other physical characteristics of each of the different species, such as specific gravity (relative weight), luster, hardness, fusibility, optical properties, and color. The latter is usually variable, and hence not characteristic of a mineral.

CHEMICAL MINERALOGY considers the character of minerals as chemical compounds, embracing also methods of using chemical tests as an aid in this determination.

DESCRIPTIVE MINERALOGY shows the classification of minerals and a description of the various species and their varieties as found in nature.

Although the ancients recognized many of the gems, and the minerals containing the useful metals, their knowledge of mineralogy was very crude. It was not until the development of modern chemistry, about the begin-

ning of the 19th century, that minerals began to be properly studied and classified.

In 1820, Mohr, of Vienna, presented a system of grouping minerals upon their similarity of form, taste, luster, gravity, streak, hardness, etc. In the methods now in use in this country, the system of Mohr is very largely followed, with additional aid from blowpipe examination and simple chemical tests. When new species are being described, the chemical analysis and the determination of the crystalline form must be very complete. A mineral species always has a definite chemical composition which varies only within certain limits, and, if it crystallizes at all as most minerals do, it has always the same general form. When a substance crystallizes in two distinct forms in nature, these are looked upon as different minerals and are given separate names.

Minerals vary greatly in hardness from soft substances that may be scratched with the finger-nails, like gypsum, to the hardest stones, as the sapphire and diamond. The same wide difference exists as to their color, even in the same species, as, for example, in the mineral tourmaline, which exhibits different shades of brown, blue, green, red, and is sometimes colorless, and frequently black and opaque.

The study of minerals has led to the development of the science of *crystallography*, but most chemical compounds (see CHEMISTRY) that are prepared artificially are also capable of forming crystals, and crystallography is applied to them as well as to the natural substances.

All the minerals that crystallize, as well as all artificial crystals, may be arranged in six groups or systems, according to the relation of the faces to certain imaginary lines passing through them, termed axes.

The Isometric system has three axes, all at right angles to each other, and of equal lengths. A familiar example is fluorspar, which usually occurs in cubes.

The Tetragonal system has three axes at right angles, but one of them may be of varying lengths as compared with the other two. The mineral zircon crystallizes after this form.

The Orthorhombic system has three axes at right angles, but all unequal. Stibnite or antimony sulphide belongs to this system.

The Monoclinic system has three unequal axes, two at right angles and one oblique. The common mineral hornblende illustrates this form.

In the Triclinic system, all the axes are of unequal lengths, and at varying angles with each other. A number of the feldspars are classed here.

The Hexagonal system has three axes at angles of 60° with each other, and a fourth at right angles to the plane of the other three. Beryl is a familiar example of this system.

While each mineral species that is crystallized follows its own form of crystallization, there are numerous modifications of the planes and angles of all the systems, giving rise to many complex forms. The molecular arrangement of minerals, which results in their crystalline form, also influences their capacity for transmitting light and heat. The form of the crystals in various minerals is often complicated also by what is termed "twinning," when one or more parts in a crystal are in a reversed position to the other parts. This gives rise to many beautiful and complex forms. The dendritic form of magnetite between two flakes of mica is an instance of such "twinning."

Minerals have doubtless been formed in four principal ways: (1) by the solidification by cooling of molten masses, as, for example, the quartz, feldspar, and mica of granite; (2) by the action of heat upon rocks below the point of fusion, as in the formation of garnets in mica-schists; (3) by the action of water dissolving substances in one place and depositing the same or other compounds in another place, as in the deposition of calcite in veins; (4) by the action of volcanic gases, which, upon cooling or coming in contact with substances with which they act chemically, deposit certain minerals. It is not always easy to decide in what way a given mineral has been formed, and it is evident that certain minerals may be deposited in more than one way.

An interesting and peculiar condition of some mineral species is what is known as "pseudomorphism," where one mineral is replaced by another which usually retains the form of the original crystal. This arises from the substitution of one mineral for another, as, for instance, smithsonite after calcite. Here the calcite crystals seem to have been gradually dissolved, while the smithsonite replaced them. Petrified wood, which is common in many places, occurring in Arizona in the shape of whole forests of silicified tree trunks, is an example of pseudomorphism. Here the action has evidently been from the infiltration of water charged with silicic acid through the beds in which the forests were buried and as the original wood decayed or was dissolved away, the silica, in the form of rough opal, took its place.

Dana's *Treatise on Mineralogy*, as revised to the present time, may be considered to be the standard for descriptive mineralogy. Brush and Penfield's *Blowpipe Analysis* is the most elaborate work on determinative mineralogy. Mineralogy in the United States, as bearing upon ornamental and precious stones, has been lately dwelt upon in detail in *Gems and Precious Stones of North America*, by George F. Kunz. H. L. W.

Min'eral Waters are, strictly speaking, waters impregnated with mineral solutions by natural processes; but the term is commonly applied to all waters which possess real or even fancied therapeutic value other than that of ordinary water. In consequence "hot

springs" are often spoken of as "mineral springs" when used for medicinal purposes. The ancients had great faith in all waters which felt or tasted other than the common "springs which run among the hills." Josephus mentions the visits of Herod to the warm baths of Calirrhoe near the Dead sea. Tiberias was famous for its springs of hot sulphur water. The Romans frequented the gaseous springs situated in southern Italy, much visited by tourists to-day. The springs of Karlsbad, Aix-la-Chapelle, Baden-Baden, and Ems are well known. In our country, Saratoga has been a resort ever since the settlement of the state of New York, and its popularity is to-day greater than ever. White Sulphur Springs, in Virginia, have rivaled the northern spa in the favor of the people. It is impossible to divide the springs into any well-defined classes as "salt springs" often contain sulphur, and "alum springs" may hold in solution a dozen other minerals besides the one giving the water its name. The best known springs, those at Saratoga, contain more of chloride of sodium (common salt) than of any other or all other mineral substances, bicarbonate of lime standing second, and bicarbonate of magnesia third. It is the presence of carbonic acid gas which gives to these springs their delightful effervescence. The value of mineral waters sold in the United States amounts annually to over $5,000,000, which amount is sure to be greatly increased as facilities for handling the product are improved. There are in the United States about 300 springs whose waters are bottled and put on the market.

Min'eral Wool is the name given to the thread-like filaments produced by the action of steam or compressed air upon vitreous substances when in a molten state. The product is also called silicate cotton by some, as the principal material in the product is silica. The fibers produced are used to incase boilers and steam pipes, thereby preventing the diffusion and waste of heat. It is also of great value in deadening sounds. As it will not burn or rust and is not subject to the depredations of insects, it is of great value in many mechanical adjustments and its use increases every year. The best mineral wool is obtained from the melting of a cinder made by mixing together four parts of orthocase feldspar and six parts of dolomitic limestone.

Miner'va, in Roman mythology the goddess of wisdom. She seems to be the same as the Greek Athene and Pallas. She was said to have sprung in full armor from the head of Jupiter. She was the patron god of Athens, and her statue by Phidias adorned the Parthenon. In her hand she carried the spindle, needle, and spool, and was skilled in all kinds of woman's work. She was patroness of art and trades; painters, teachers, and physicians invoked her aid. Minerva, like Athene, is represented in art with a grave and majestic countenance, armed with helmet, shield, and spear. The olive branch, the serpent, and the owl, were sacred to her. Her festival, held in March, lasted from the 19th to the 23d.

Minie (*me-ne-ā'*), **Claude Etienne,** a French inventor, born at Paris, in 1804. He served in the army, rising from the rank of a private soldier to that of major. His experiments in the improvement of firearms resulted in the invention of the Minié rifle in 1849. He made improvements also in rifle balls, cartridges, and gun barrels. In 1858, he was appointed director of a military school at Cairo, Egypt, by the khedive. He died in 1879.

Min'ing, the process by which mineral matters of commercial value are taken from their natural position and made available for shipment. The substances mined consist not only of metals and the ores of metals, but of various non-metalliferous substances, such as coal. In the broadest sense of the term, mining may also be made to include the winning of such subtances as natural gas, mineral oils, clay, building stone, natural fertilizers, salt, etc., though other terms are commonly applied to the processes by which these substances are made available.

Occurrence.—The materials mined occur in various forms, chief among which are (*a*) bedded deposits chiefly beneath the surface, (*b*) vein deposits, and (*c*) surface deposits.

(*a*) Bedded deposits include (1) such bodies of valuable mineral matter as lie in beds essentially parallel to the associated layers of rock, and (2) deposits which are disseminated through stratified rocks. Examples of (1) are many iron and all coal beds. An example of (2) is the copper in the conglomerate beds of the Lake Superior region. The former (1) are really layers of rock, formed later than the rock which lies below them, and before that which lies above. The second group (2) are usually of secondary origin; that is, the valuable mineral matter was concentrated where it now is, after the rock was formed.

(*b*) Veins are the fillings of cracks or fissures in rock. The filling is generally accomplished through the agency of underground water, which dissolved the mineral matter from the rock, brought it to the fissures and there deposited it. Veins are called mineral veins, or often "lodes,' if the material is valuable for commercial purposes. The walls of veins are often impregnated with useful mineral matter like that of the vein proper, and the term "vein" is then made to cover those parts of the walls which contain the valuable matter, as well as the vein itself. Veins differ from bedded deposits in that they are usually more irregular, less continuous, and have no definite relation to the bedding planes of the rock. Both bedded and vein deposits may be horizontal, vertical, or inclined at any angle. Bedded deposits

were usually horizontal to begin with, but the beds of ore, coal, etc., may have been tilted the same as the beds of rock above and below. Veins likewise occur in any position, depending on the direction of the fractures in which the vein stuff was deposited.

(*c*) The third class of ore deposits is represented by gravel, sand, or earthy material, in which there is some useful mineral which can be extracted with profit. Thus, certain deposits of sand and gravel, like those of Cape Nome, and various mountain valleys of the western part of North America, contain gold. Tin ores sometimes occur in the same way. In such deposits, mines are opened. The specific gravity of both gold and tin is much higher than that of the associated sand and gravel, and this fact is taken advantage of in mining. Running water is caused to flow over the gravel and sand, with a current which can be regulated. It washes away the lighter material, leaving the desired metals or ores behind. This is the principle of the method known as *placer mining*. Mines in these loose surface materials are *placer mines*. Certain other surface deposits are mined, but in a very different way. Thus, in certain marshes and bogs, bog iron ore accumulates. This is, in reality, a bedded deposit, but is of recent origin, and not buried beneath later beds of rock or sediment. If worked at all, the ore is taken out bodily. Bog iron ore is at present but little used.

The Problems of Mining. — After the existence of valuable deposits of mineral matter has been determined, many conditions affect the method of mining it. These conditions are so complex that they must be considered individually in the case of each mine. In each case the methods must be adapted to the local situation. The aim is always to extract the maximum amount of ore with the minimum expenditure of time and money, and with the least danger to life and property. The first things to be determined are: (1) the shape and position of the ore body; whether it is in distinct beds or veins, or disseminated through a large mass of rock; whether the veins or beds are horizontal, vertical, or oblique, etc.; whether it is near the surface, far from the surface, or both; (2) the extent of the ore body; (3) the character of the ore itself as regards hardness, tenacity, etc.; (4) the nature of the rock in which the ore occurs, so far as concerns its hardness, texture, structure, etc.; (5) the topography of the immediate locality where the mine is located. Questions of another sort, such as facilities for transportation both to and from the mine, water supply, fuel supply, etc., have to be considered in connection with every mine.

Various means are employed for the determination of the exact position of the ore body. This is the work of exploration. Exploration is carried on partly by sinking small test pits; partly by "stripping" the loose material from the surface, exposing the rock which contains the substance to be mined; partly by shafts sunk into the rock; partly by the help of the compass, as in the case of magnetic iron ores; and partly by means of drill holes. In each case, the methods of exploration best fitted to the situation should be adopted. The test pits are very much like open, shallow wells. The stripping of the surface is the method often adopted where the mineral vein comes to the surface of the rock, but is covered by soil and other loose débris. Vertical shafts are often sunk alongside the vein, and tunnels or cross-cuts are then run from the shaft across the vein. Veins are often cross-cut in this way in many places, by way of exploration. The drills which are used in preliminary tests are hollow iron tubes having an inner diameter of one or two inches. In the "bit" at the lower end of the tube, diamonds are set. With the bit resting on the surface of the rock to be drilled, the tube is made to rotate at high speed, and cuts its way down into the rock. A cylindrical core of rock appears in the tube, or "core barrel," as the drill descends. Water is constantly pumped down the inside of the tube, and rises between the drill rods and the wall rock, washing up the fine grindings of the drill. With the drill it is possible to obtain specimens of the rock at various depths, and this is often of value in the further work of the mine. Drill holes have been made several thousand feet deep. This method of exploration is expensive, but effective.

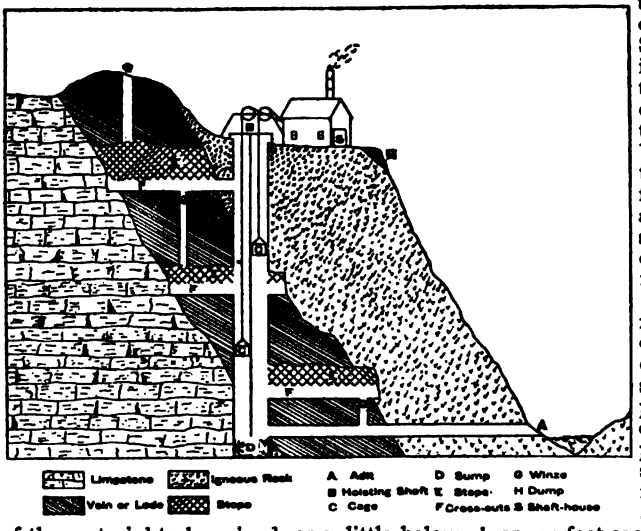
Another problem with which the miner has to deal is the approach to the ore body. Roughly speaking, mining methods may be divided into two general classes: (1) surface mining or "open work," and (2) underground mining.

Open work is done where a small amount only of worthless material must be removed in order to uncover the deposit. This method is employed, for example, in the iron mines in the Mesabi range in Minnesota, where the ore is covered only by glacial drift, 10 to 100 feet thick. Such covering may often be stripped off with steam shovels. Where the ore is soft and friable, as in the case of some of the iron ore of the Mesabi range, it too can be removed by steam shovels; but if the material to be mined is hard, it is blasted and taken out in masses.

In underground work, the cheapest and easiest method, if the topography and the position of the material to be mined permit, is to approach the ore by tunnels. This may be done where the ore body lies in the side of a hill or mountain, so that it may be approached from the side. If the ore can be taken out through a tunnel, it saves the expense of hoisting it up through a shaft. The tunnel often also saves the expense of pumping out the water, which is often a troublesome factor in mining. In many cases,

however, it is necessary to approach the ore by a shaft. The shaft may be either vertical or inclined, according to local conditions, and especially according to the position of the ore body. The inclined shaft is sometimes known as an "incline." A shaft is usually rectangular in section. In very small mines, it may be no more than four feet square, but in large mines the shafts are much larger, large enough to permit the working of at least two hoists, called "cages" or "skips." There must also be room for pipes, both for carrying down compressed air and for the carrying out of water. Large mines frequently have shafts as much as 12 x 18 feet in diameter.

If the material to be mined lies in a horizontal bed, the shaft is sunk down to the level



of the material to be mined, or a little below. Tunnels are then made, leading sidewise from the shaft into the substance to be mined. The material to be mined is worked out along these tunnels, carried to the shaft and hoisted to the surface. When the material which is being mined is worked out, it is often necessary to put in timbers to keep the mine open. If, for example, a horizontal bed of coal is being mined, the taking out of the coal leaves the rock above unsupported. Timbers may be put in to hold up the roof, or columns of coal may be left here and there, to serve the same purpose. Where practicable, the tunnels driven from a shaft are made to rise slightly from the horizontal, so that the water encountered in the tunnel may drain into the "sump" or pool at the bottom of the shaft. From the sump it is pumped out. The slight inclination of the tunnel also facilitates the transfer of the substance mined to the shaft. If the tunnels are parallel with a mineral vein, they are called "drifts." When they cut the vein, they are called "cross-cuts." "Tunnel" is a rather indefinite name which may be applied either to drifts or cross-cuts. The process of drifting and cross-cutting is called "driving a level." Tunnels are usually as much as 6 x 6 feet in section. Tunnels are often run at various levels; for example, tunnels may be run at the 50-foot level (that is, 50 feet below the surface), at the 100-foot level, at the 150-foot level, and so on. When the drifts and cross-cuts have been made, and the different levels put in communication by vertical shafts, the ore between the various openings is said to be "blocked out."

Some ore has been extracted in the process of blocking out the ore. When a body of ore has been blocked out, its extraction begins in earnest. The processes employed for loosening the substance to be mined are various. Sometimes it is loosened by the pick, or by other sort of hand-tool. Sometimes it is already soft or incoherent. Often it is so hard that it must be blasted. Ore is often worked from below rather than from above. That is, ore between the 50 foot level and the 100 foot level, is often worked from the latter, and carried along it to the main hoisting shaft. The working out of the ore between levels is "stoping."

Another problem which the miners have to encounter is the drainage of the mine. In most deep mines the amount of water seeping in is great, and must be pumped out about as fast as it enters. For this purpose force pumps are used. In deep mines several or many force pumps may be needed. Pumps which are able to elevate the water 300 or 400 feet each are in common use. In mines near deep valleys, it is sometimes possible to secure drainage by driving a drainage tunnel or "adit" from the shaft to the valley.

Still another problem which has to be faced in mining is that of ventilation. In coal mines where noxious gases are sometimes plentiful, in mines where many men are at work, in mines where there is much blasting, and in deep mines where the temperature is high at the bottom, ventilation is of the utmost importance. Ventilation may be either natural or artificial. In shallow mines the hoisting shaft is usually large enough for ventilation. If there are several shafts connected with one another, the circulation of the air in the mine is facilitated. If there is an adit, it helps still further. Artificial circulation is secured by fans placed at the entrance of mines, or by the use of compressed air which is carried into the mine. Compressed air is often introduced for power, and as it escapes it serves for ventilation as well.

TRANSPORTATION.—When the material to be mined has been loosened from its natural position, it is carried to the main gangways in barrows, chutes, or cars. In the main gangways are tramways. The cars are of iron or wood, with wheels close enough together so that the cars can be run on short curves. The motive power is furnished by men, mules, steam engines, or electricity. In vertical shafts the material is hoisted in buckets or "cages." In inclined shafts, the hoisting is done with "skips." The skips are on wheels, the rear wheels being much larger than the front ones, and when the skip reaches the horizontal dumping platform at the top, the forward pitch dumps the ore automatically. The hoisting power, in the case of large mines, is steam or electricity.

ORE DRESSING.—In most instances the ore must be subjected to a preliminary treatment before it is fit for metallurgical processes. The method of treatment varies with the ore. In many cases the masses and lumps of ore are crushed, or even ground to powder, often by the pounding of huge hammers in a stamp mill. The valuable part of the ore is then separated from that which is without value, the process of separation being different in different cases. Where the ore is much heavier than the waste, the separation is brought about through differences in specific gravity. The final extraction of the metal, like the preliminary treatment of the ore, differs with the nature of the ore. Gold, for example, is passed over a copper plate coated with mercury. The mercury forms an amalgam with the gold, and is afterward separated from it by heating until the mercury is volatilized. At this stage the product passes from the hands of the miner to the hands of the metallurgist. Ores of other metals are treated by other processes. The concentration of the crude ore is "milling." Under this term, the extraction of the metal from the ore is also sometimes included. Properly speaking, the process of mining ceases when the ore is ready for the mill, or for shipment.

R. D. SALISBURY.

Mink, a carnivorous animal valued for its fur. It is related to the weasel, but is stouter in the body and has a more bushy tail. It is adapted to a life in the water, but also lives partly on land. Minks make burrows and nests in the banks of streams. They feed on fish, reptiles, mollusks and crustacea, and also on muskrats, rabbits, etc. The American mink is fifteen or twenty inches long, with a tail of eight or nine inches. It is widely distributed in North America in places suited to its mode of life. Its color varies from light yellowish-brown to rich blackish-brown. The darker the color the more highly prized is the fur. The European mink is a little smaller than the American mink, and is more northern in in its range. The Siberian mink has fur of a clear tawny-brown color.

Min'neap'olis, a city of southeastern Minnesota, is situated on both sides of the Mississippi river, about seven miles from St. Paul, though the interval between is so built up as to make them really one city. The name is from the Sioux word "Minne," meaning water, and the Greek word for city. The falls of St. Anthony, with a descent of sixteen feet, furnish the water-power which has built up the city. The Mississippi is crossed by twelve bridges.

Minneapolis is one of the most enterprising and important of the younger cities of the United States. Its rapid growth is shown in the fact that from 46,887 in 1880, the population advanced to 202,718 in 1900. The basis of growth is found in the location of the city with reference to the great wheat and lumber interests of the northwest. It is the greatest primary wheat market of the world. The wheat product of Minnesota is greater than that of any other state in the Union. More than half of this is here manufactured into flour, while not only the product of Minnesota, but a large part of the yield of the great fields of the Dakotas finds a market here. A single one of the great flouring mills of the city has a capacity of 25,000 bushels per day. The elevators of the city have a storage capacity of about 20,000,000 bushels. The great timber industry of the upper Mississippi valley finds its chief market and manufacturing center in Minneapolis. All the great trunk lines of railroads in the northwest run to or through Minneapolis, giving to the city unexcelled transportation facilities. Among the notable buildings are the Chamber of Commerce, the Exposition building, the Lumberman's Exchange, the West hotel, and others. Here are located the University of Minnesota, Hamline university, Augsburg Theological seminary, and Macalester college, besides several seminaries and professional schools. The public schools are of high grade, efficiently organized and well equipped. There are 60 school buildings; the teaching force numbers 853; and there are 37,532 pupils enrolled.

Minneha'ha, Falls of, are near Fort Snelling, about five miles from Minneapolis on a little stream flowing from Lake Harriet and Lake Calhoun. They are 59 feet high, and though not a large body of water, the spray and sparkle of the waters together make it deserve the name "laughing water," which is the meaning of the word. Longfellow has made it famous in his *Hiawatha.*

Minnesingers (*min'e-sing-ers*), a name applied to the lyric poets of Germany who flourished from the middle of the 11th to the close of the 13th centuries. They, however, not only wrote the poetry, but composed the music for their love songs. They sang mostly of love, as the word "minne" indicates, and often roamed from castle to castle, and from court to court, like the troubadours reciting or singing their songs. The chief exponents

of this feudal verse are Walther von der Vogelweide and Wolfram von Eschenbach. The songs of 160 of these singers are preserved. After the decline of their art, the Meistersingers took their place. Unlike the Minnesingers, who were of the knightly or courtier class, the Meistersingers were men of the artisan class, and formed themselves into guilds and wrote poems as they plied their tasks. Though there is little real poetry in the songs of the Meistersingers, they were popular for three centuries, the last guild being dissolved in 1830.

Minneso'ta, a river which crosses the state of Minnesota. It rises near Lake Traverse, on the Dakota border, and widens into Big Stone lake, which stretches for 30 miles along the same border, flows southeast until nearly across the state, then with a sharp turn flows northeast into the Mississippi at Fort Snelling, five miles above St. Paul. It is 450 miles long and navigable for 300 miles.

Minneso'ta belongs to the northern group of states, lying next to Canada. Its land surface is approximately 79,205 square miles, and is larger than Ohio and Indiana. The state contains the sources of the three great river systems of North America. The Red river of the north sets out here for Hudson's bay; the St. Louis river and others, entering Lake Superior, find their way to the Atlantic ocean, and the Mississippi starts from Lake Itasca on its long journey to the gulf of Mexico. The Mississippi travels for 797 miles through Minnesota, now through rapids and falls, as at Sauk Rapids and St. Anthony, and now broadening out into lakes, as Lake Pepin. It is navigated to within 270 miles of its source. Minnesota is a rolling prairie, with few hills, none over 1,200 feet high. Two-thirds of the state lies in the Mississippi valley. In the eastern part is one of the most valuable forests of the west, called the Big Woods, 100 miles long and from 10 to 40 miles wide. The ten thousand lakes of Minnesota, of every shape and size, with wooded islands, and bays and waters filled with choice fish, add to the beauty and wealth of the state. The climate is severe in winter, but dry and bracing, with a light snowfall. The soil is fertile, with extensive swamps in the north, and many acres of land yet uncultivated. The hard spring wheat of the state is the best in the world, while other products are corn, oats, potatoes, and apples. It is also a stock-raising state. The great forests, which still cover half the state, give it an enormous lumber trade; and this source of wealth is guarded by encouraging tree planting, over 30,000,000 trees having been set out on the prairies. The iron mines of the Vermillion range, 100 miles from Duluth, produce ore very rich in iron, and belong to an ore field reaching to the Mississippi. There are large quarries of fine building stone, including the pipe-stone quarry, situated on a ridge, rising 450 feet, and where the Indians came for the red stone that could be easily carved into pipes. Minnesota has 7,303 schoolhouses, with close upon 400,000 pupils. The State university, opened in 1869, is a mile below St. Anthony's falls, with a total number of 3,236 students and 120 instructors. The farm connected with the agricultural college is two miles from the university, and covers 250 acres. Macalester college at St. Paul; Carleton at Northfield; St. John's (Roman Catholic) university at Collegeville; the Parker (Free Baptist) college at Winnebago city; the Augsburg (Lutheran) seminary at Minneapolis; the Gustavus Adolphus (Lutheran) college at St. Peter; St. Olaf college and Hamline university at St. Paul, are a few of the higher institutions of learning. The population, made up of settlers from New England, and foreigners, mostly from northern Europe, — Swedes, Norwegians, Danes, Russians, Icelanders, Lapps, and Finns — with 9,000 Indians of the Chippewa tribe, numbers 1,751,394.

Minnesota was first visited by French fur traders and priests in 1659. The part of the state west of the Mississippi came into the Union by the Louisiana purchase. The part east of the Mississippi had been ceded to Great Britain by France in 1763 and belonged afterward to Virginia, who ceded it to the United States. Fort Snelling was built in 1821. After the Chippewas surrendered their lands east of the Mississippi immigration set in, and in 1849 Minnesota became a territory and in 1858 a state. The capital is St. Paul, population 163,065.

Min'now, the name commonly applied to small slender fishes. The true minnows belong to the family *Cyprinidæ*. They are abundant in the Old World and in North America. Although numerous in species they are difficult to distinguish on account of great similarity. Like birds, the male minnows often put on bright colors during the breeding season, and some kinds have the head ornamented with tubercles. The so-called American minnows (*Notropis*), with upward of one hundred species, are confined to the waters east of the Rocky mountains. Minnows are of importance as food for larger fishes, and they are extensively used as bait by fishermen.

Minor'ca, one of the largest of the Balearic islands in the Mediterranean belonging to Spain. It lies to the north of Majorca island, and is 28 miles long and about 10 miles wide, and covers 284 square miles. It has a rocky coast, with many inlets, and a fertile soil. It has also a great number of ancient remains and stalactite caves. The principal cities are Port Mahon, and Ciudadela. It was ceded to Spain by England in 1802. Population 40,000. See *Balearic Islands*, by Bidwell.

Minotaur (*min'ō-târ*), a Grecian myth, represented as a man with the head of a bull. He was fed with seven youths and seven

maidens, sent from Athens at certain periods, until slain by Theseus with the help of Ariadne.

Mint, a general name of species of the great family *Labiatæ*, but specially applied to the species of the genus *Mentha*, ordinarily recognized by their peculiar fragrance and their clusters of small purple, pink, or white flowers. The genus contains about 30 species, all of them native to north temperate regions, 12 of which are either native or naturalized in North America. Peppermint (*M. piperita*) is the most important species in cultivation, and is one of the most important of plants in the production of essential oils. Spearmint (*M. spicata*) is also cultivated for its essential oil, but this is not so much in demand as peppermint oil. It is spearmint which is cultivated largely for table use in the making of mint sauce and mint julep. The chief regions of peppermint cultivation in the United States are certain portions of Michigan, Indiana, and New York.

Mint, the place where money is coined by the government of a country, though in early times in England the bishops and barons had the privilege of coining. Until the middle of the 16th century, coins were made from pieces of metal cut and hammered. In 1662, the use of the screw or mill became common in England. It was the invention of a French engraver, Antoine Brucher. The gold or silver to be coined is melted and has added to it the amount of copper needed to make it hard enough for use, and is formed into bars. In the United States, the silver coins are one-tenth copper and nine-tenths silver, and in the gold coins one-tenth is an alloy or mixture of silver and copper and nine-tenths gold. The bars are then passed between rollers which flatten them into strips or ribbons of the right thickness. The gold bars are usually rolled ten times before they are thin enough, and the bars of silver eight times. The strips are finally drawn between steel blocks to make them straight. The strips are then cut into pieces of the right size, or blanks, which in the gold coins are weighed by hand before being finished off. If too light, they are sent back to be melted again, and if too heavy the edges are filed off. This is usually done by women, as their delicacy of touch fits them for the work. The blanks are now passed through the milling machine which finishes the rims of the coins, and then into the coining press, where they are stamped with the figures and letters of the different coins. After a careful weighing and inspection and counting, they are put into bags and are ready for circulation. There are in the United States five mints — at Philadelphia, New Orleans, San Francisco, Carson City, and Denver, and several assay offices where the metals are prepared for coinage. The mints are under the direction of a branch of the treasury department, called the bureau of the mint. The earliest money coined in the United States was copper cents in 1795, at Philadelphia, where the first mint was established.

Min'to, Gilbert John, fourth earl of, governor-general of Canada since 1898, and previously known in the Dominion under his junior title of Viscount Melgund, was born in 1845. Early in his career he entered the Scots Guards, was attached to the Turkish army on the Danube in the Russo-Turkish war of 1877, served in Afghanistan in 1879, and two years later accompanied Sir Frederick (now lord), Roberts to South Africa as military secretary. From 1883–86 he was military secretary to Lord Lansdowne, then governor-general of Canada, and chief of staff in a short campaign against the insurgent Riel in the northwest territories of the Dominion. He succeeded to the earldom in 1891, and in 1898, was appointed governor-general of Canada. Residence, Ottawa.

Mirabeau (*mē-rä-bō'*), **Honore Gabriel Riquetti,** Count de, a great French statesman, was born at Bignon, in Provence, France, March 9, 1749. He was badly scarred by smallpox at three years of age, and had one foot twisted, and an unusually ugly face, yet his great ability and a personal power of fascination made him the idol of his companions. His father, a tyrant in his home, placed him in the army and twice secured his imprisonment. His life was wild, and at one time he was condemned to death for his flight with a married woman. While in prison he wrote his famous essay on *State Prisons*. After his release, he succeeded in having the sentence against him repealed, and made himself famous by his eloquent appeal in his own behalf. He spent his next years in writing pamphlets and books, and while on a secret mission of the government at Berlin, obtained the materials for his *History of the Prussian Monarchy under Frederick the Great*. His political life began with the stormy days preceding the revolution; and in the national assembly when the king commanded the deputies to separate, he made the memorable answer, "We shall yield to nothing but bayonets." His dream was to place the king at the head of the revolution and reform the government by a new constitution, guarded by a ministry, somewhat after the pattern of the English parliament. He tried to make terms with Lafayette and Necker, suggesting their names for the new ministry. He labored incessantly and with great power, but was opposed by the queen and mistrusted by the better classes in either party. "The sins of my youth," he bitterly exclaimed, "are giving me their full punishment now." In 1790, he was made president of the Jacobin club and administrator of the Seine department, and later one of its eight directors. In January, 1791, he was made president of the assembly. He

opposed the law against emigration, and the proposal that at the king's death a regent should be elected by the assembly. His health, ruined by his early excesses and his tremendous labors, was failing, and with prophetic foresight he said, "I carry with me the ruin of the monarchy." He died at Paris in his forty-third year, April 2, 1791, and was buried in the Panthéon. "Do not rejoice over the death of Mirabeau," said the king to his wife; "we have suffered a greater loss than you imagine." His was the one influence that might still have saved the throne. See *History of the French Revolution*, by Carlyle; *French Revolution*, by Michelet; *French Revolution*, by Taine.

Mir'acle Plays or **Mys'teries**, were plays performed in the middle ages, the subjects of which were taken from the Bible, or the lives of saints. Miracle plays were founded on legends, and the mysteries on the history of the Bible, but the distinction was not carefully observed. The plays were at first performed in the churches by the clergy and their assistants, but afterward on stages erected in the streets, and at one time every important place had its band of players. The first known specimen of these plays dates back to the 4th century. In 1110, in Dunstable, England, was exhibited the play of St. Catherine, the earliest mentioned in England. They were used at first as means of religious instruction, but became gradually corrupted by jests and vulgarities. After the Reformation they slowly declined, though the first blow against them came from the Catholic church on the ground of their irreverence. The only modern instance of these plays is the Passion Play, which is performed once in ten years at Oberammergau, in Bavaria, as the townspeople pleaded successfully to be excepted from the general condemnation in 1779. (See OBERAMMERGAU.) See *Miracle Plays*, by Hase; *English Miracle Plays, Mysteries, and Moralities*, by Pollard.

Mirage (*mi-rasĥ'*) is an appearance of an object in the sky, or at sea above the water, produced by the rays of light changing their direction when they pass through a layer of either hotter or colder air. The mirage of the desert is thus the effect of the heating of the layer of air next the ground by the hot sands, thus bending the rays of light upward; while over water the effect is produced by the rays of light being bent as they pass from the cool layer of air next the water into hotter air above. Sometimes the object is seen in the sky upside down, occasionally only slightly raised, and sometimes there will be two objects, one upright and the other reversed. These effects are all explained by the different layers of hot and cold air through which the light passes. There have been some very remarkable mirages; such as the "Fata Morgana," in the straits of Messina, where men, houses, and ships are seen, sometimes in the water and sometimes in the air. Captain Scoresby, while cruising off the coast of Greenland, discovered his father's ship by its image or reflection in the sky. In the Baltic sea, in 1854, the English fleet of nineteen vessels, 30 miles away, was distinctly seen floating in the air. See *Optics*, by Brewster.

Miramon (*mē-rä-mōn'*), **Miguel**, a Mexican general, was born in the City of Mexico, Sept. 29, 1832. While still in the military academy, he, with his fellow students, were engaged in defending Chapultepec in the war with the United States, and he was taken prisoner. Entering the army in 1852, he became colonel in 1855, and general when twenty-five years of age. When in command of a body of troops, he headed a rebellion against Alvarez, the president of the country at the time, and took the city of Pueblo, which he twice defended within six months, the second time for forty-three days, against 10,000 besiegers. He kept up his opposition to the government, as the head of the church party, and was finally chosen president, in 1859, but declined the honor, reinstating Zuloaga, who retired in a few days, leaving Miramon in command. The war continued until 1860, when the Liberal party gained power and Miramon fled to Europe. There, Maximilian, to whose fortunes he adhered, made him grand-marshal and minister of Mexico to Berlin. He returned to Mexico in 1866, when Maximilian was reigning, and the latter persuaded him to give up his intention of resigning, and as chief of the army he was captured and shot at Querétaro, with Maximilian, June 19, 1867. See *Mexico under Maximilian*, by Kendall; *Young Folks' History of Mexico*, by Ober; *Mexico and Her Military Chieftains*, by Robinson.

Mir'iam, the sister of Moses, who guarded him when, as an infant, he was placed by his mother in a basket by the river Nile, to avoid obeying the king's command to destroy all the male children. She called her mother as nurse when the babe was found by the daughter of Pharaoh. She is called a prophetess, and her triumphal song at the head of a procession of women, after passing the Red sea, is given in Exodus. Rebelling with her brother Aaron against Moses, she became a leper, but was healed by the prayer of Moses.

Mir'ror, a surface capable of reflecting light. Ancient mirrors, now found in tombs and sepulchral vaults, were made for the most part of solid, highly-polished metal; but upon the use of glass becoming common, that material took the place of heavier substances. The backs of the first glass mirrors were covered with a thin coating of lead, but the glass workers of Venice introduced, in the 17th century, an amalgam of mercury and tin which answered the purpose much better. A solid and perfectly level table of stone is first covered with a sheet of tin-foil, over

which a quantity of mercury is poured, raised edges preventing the loss of the same. Upon this liquid mercury a carefully-prepared plate of glass is slid in such manner as to exclude all air bubbles and all impurities. The superfluous liquid is then run off, and by means of delicate and uniformed pressure the amalgam is made to adhere to the glass. The plate being lifted from its position is turned with the coated side uppermost to dry. This process sometimes requires weeks. Owing to the injurious effects of the vapors of quicksilver upon the health of workmen, the attempt has been frequently made to substitute a continuous film of silver for that of mercury, but the process has been attended with uncertain results. Concave mirrors have been used for focusing the rays of the sun, and a sun-motor has lately been constructed in California, where mirrors arranged in a circle thirty-two feet in diameter are made to generate steam and to pump water into irrigating canals.

Mississippi (*mis-i-sip'i*), the largest river in North America, and, if calculated from its mouth to the source of the Missouri, its largest branch, the longest river in the world. It rises in Minnesota, in Lake Itasca, is 2,960 miles long, or with the Missouri, 4,200 miles, and drains all the country between the Alleghenny and Rocky mountains, a region nearly as large as half of Europe. It has about 16,000 miles of navigable waters. The largest tributaries are the Missouri, Arkansas, Red, White, Yazoo, and Ohio rivers, and, besides these, about 240 smaller ones. There are falls at Minneapolis, Rock island, and Des Moines rapids. The river begins with a width of 12 feet, widening to 4,700 feet below the mouth of the Ohio, and measuring 2,500 feet at New Orleans. It flows, in the lower part of its course, through lowlands, often below the level of the river, and protected by embankments for over 1,600 miles. After receiving the waters of the Red river, the Mississippi divides into many separate channels, called bayous, each making their way to the gulf of Mexico, where it forms what is called the delta. The water of the Upper Mississippi is clear, but gradually grows dark and muddy as the great rivers along its course pour their turbid currents into it. It carries yearly into the gulf enough earth to make a square mile of land 263 feet thick. These great deposits obstruct the mouth, and the government has expended large sums in providing a system of jetties or walls to protect the channel. (See BREAKWATER.) The river from the mouth of the Ohio is subject to extensive floods, the water stretching for miles over the lowlands, many of which are uncultivated because of this danger. The levees or embankments to prevent floods have been extensively built by the United States, and cost a large amount yearly for repairs. The first white man to discover the waters of the Mississippi was De Soto, in 1541, and in 1673, Marquette and Joliet descended it nearly to its mouth, while La Salle sailed to the gulf and took possession of the country for his king, in 1682. See *Physics and Hydraulics of the Mississippi River*, by Humphrey and Abbot.

Mis'sissip'pi, one of the southern states of the Union, lying on the Mississippi river. It covers 46,810 square miles (the total land surface is 46,340 sq. miles), and is 335 miles long and 150 broad — about one-sixth the size of Texas. It has several large rivers — the Yazoo, 264 miles long, flowing into the Mississippi, the Pearl, and the Tombigbee into the gulf of Mexico. The country is hilly, without mountains, except in the Mississippi bottom lands. These lands, lying between the Mississippi and the Yazoo rivers, are protected by levees, the funds for the purpose being raised by a tax on every bale of cotton. The coast line of the state is only 90 miles, and is separated from the gulf of Mexico by the Mississippi sound and a range of low islands. There are several fine mineral springs, the resort of tourists. The state is mainly agricultural, cotton being the great crop, besides corn, oats, rice, and potatoes. Fruits and vegetables of all kinds grow luxuriantly, and are sent to the northern markets. The cotton product is second only to that of Texas. The forests are valuable, covering three-fifths of the land, the most valuable tree being the yellow pine. The winters are mild, the summers hot, though tempered by the gulf breezes. The University of Mississippi, founded in 1848, is near Oxford; the Agricultural college, with an experiment farm, at Starkville; an industrial college for girls at Columbus, Mississippi college at Clinton, and schools for the colored youth at Tougaloo, Holly Springs, and Jackson. The capital is Jackson (population 7,816), the other chief cities being Vicksburg, Natchez, and Meridian. Population of the state 1,551,270, of which more than half is colored.

The first European to pass through this region was De Soto, but he left no settlements. La Salle took possession of the country in the name of France in 1682, calling it Louisiana. In 1699 and in 1716, forts were built on the bay of Biloxi and at Natchez. It was ceded to Great Britain in 1763. The state was organized as a territory in 1798, and came into the Union in 1817.

Missolonghi (*mis-sō-lon'gē*), a town in Greece, built on a swampy flat, and memorable for the sieges through which it passed in the struggle for Grecian independence. In 1821–22, under Marco Bozzaris and Mavrocordato, it held out for three months against the Turks. Again, in 1825, it resisted a large force of Turks for ten months; at last, putting the women and children in the center, the garrison cut their way through the Turkish army, 2,000 of them reaching the mountains. Byron joined the Greeks in their struggle at

Missolonghi, in January, 1824, and died there April 9, 1824. Statues of Bozzaris and Byron have been erected here. Population 10,000.

Missouri (*mi-zō'ri*), a river of the United States, the longest tributary of the Mississippi. The name means the "muddy river." It is so much larger and longer than the Upper Mississippi that it ought to be considered the main river, and so form, with the Lower Mississippi, the longest river in the world. It rises among the Rocky mountains, near the border of Montana and Idaho, its general direction being southeast to the Mississippi, which it reaches, after crossing the whole state of Missouri, near St. Louis. It is 2,980 miles long, and can be navigated for about 2,500 miles. A narrow gorge made by walls 1,200 feet high and only 450 feet apart, called the "Gates of the Rocky Mountains," through which the river flows, is about 400 miles from its source. And 145 miles further down the river are the Great Falls, of four cataracts, 26, 47, 19, and 87 feet high, separated from each other by rapids.

Missou'ri, one of the central states of the Union, lies on the west side of the Mississippi river. It is 280 miles long, and varies from 208 to 312 miles in width, and covers 68,735 square miles, being almost twice as large as Indiana. It is divided into two parts by the Missouri river, which flows 436 miles across the state from Kansas City to St. Louis. The north part is rolling prairie, with forests along the rivers, while the south is hilly, the Ozark mountains being in this part of the state, and reaching 1,500 feet in height, while another ridge in the southeast has many bold knobs, as Pilot Knob and Iron Mountain. Missouri is well watered, having, besides the Mississippi and Missouri rivers on her borders, the Grand Platte, Osage, and the Gasconade. There are in the state a number of curious caverns, many miles long, with hidden lakes and streams and great halls and galleries, adorned with stalactites, and also numerous groups of mineral springs. The climate is marked by extremes, lacking alike the moderating influence and protection of sea air, or sheltering mountains. It is rich in minerals, its iron fields, including Iron Mountain, which covers 500 acres, and Pilot Knob, being almost inexhaustible, and supplying a very rich ore. Lead is found in large quantities, some of the caverns having millions of pounds on their roofs and sides. It yields more zinc than any other state, and has several nickel mines, very large coal-fields, and fine quarries of stone. The soil is rich and places the state third in the value of its agricultural products. Corn, oats, wheat, hay, and fruits are the chief crops. It is surpassed only by California in the production of wine, and is also a large stock-raising country. The manufactures are flour, beer, wine, tobacco, jewelry, shoes, drugs, etc., and there is a large beef and pork-packing business. It has state normal schools, a state university (established in 1839), with an agricultural college and farm, at Columbia, and a School of Mines at Rolla. Washington university, and St. Louis university at St. Louis, Drury college at Springfield, Westminster college at Fulton, William Jewell college, at Liberty, Grand River college, at Edinburg, Missouri Valley college at Marshall, are only a few among the many institutions of the state, and her school fund is the largest of any state in the Union. The population of the state is 3,106,665. The capital is Jefferson City (population 9,964); the other large cities are Kansas City (population 163,752), St. Louis (population 575,238), St. Joseph City (population 102,979), and Joplin (population 26,023). In 1762, France ceded to Spain the territory west of the Mississippi, and St. Louis, founded in 1764, was a Spanish city with Spanish governors until 1804. The territory of Missouri was founded in 1812, and in 1821 a part of it was made into the state of Missouri, though its boundaries were not settled until 1836. The contest over the admission of Missouri into the Union ended with what is known as the Missouri Compromise, which allowed slavery in Missouri, on the condition that it should be permitted in no other state north of 36½° latitude. The state suffered severely in the Civil war, being divided in sentiment and overrun by both armies, but has been very prosperous since.

Missou'ris, a tribe of Indians belonging to the Dakotah family, first found near the Missouri river. They sided with the French against the English in the early struggles for the country. Lewis and Clarke found them in 1805 on the Platte river, numbering about 300. They had left their home in Missouri and joined the Oto tribe, with whom they have since been connected. The United States pays them $9,000 a year.

Mistletoe (*mis'l-tō*), a family of parasitic green shrubs, or herbs, which grow upon woody plants and absorb their sap by means of special sucking organs known as haustoria (which see). There are over 20 genera and 500 species, which are widely distributed, but most abundant in the tropics. The mistletoe of Europe is *Viscum album;* while the common American mistletoe is *Phoradendron flavescens*, a small, shrubby, brittle form of yellowish color and with white berries, growing in bunches on deciduous trees of various kinds. The mistletoes, which grow in abundance upon various species of conifers, especially in the western mountain regions, are species of arceuthobium, which are greenish-yellow and brown, and with small scale-like leaves.

Mitch'el, Ormsby MacKnight, an American general and astronomer, was born in Kentucky, Aug. 28, 1810. He was professor of mathematics at West Point for two years

after his graduation there; practiced law and taught in the Cincinnati college. He became director of the Cincinnati observatory, which had been built largely through his influence, and also of the Dudley observatory at Albany. In the Civil war he entered the army as brigadier-general of volunteers; was promoted to the rank of major-general, and, after various successes, given command of the department of the south, but died of yellow fever at Beaufort, S. C., Oct. 30, 1862, before entering on the campaign. He lectured on astronomy, and invented several instruments for astronomical work. His published books are, *Planetary and Stellar Worlds*, and *Popular Astronomy*.

Mitch'ell, Donald Grant, American novelist and essayist, was born at Norwich, Conn., April 12, 1822. His college course was taken at Yale college, and his law studies in New York city. He wrote under the name of "Ik Marvel." In 1853, he was appointed United States consul at Venice, and in 1868 became editor of the *Atlantic Monthly*. His best-known works are, *Dream Life*, *Reveries of a Bachelor*, *My Farm at Edgewood*, *Wet Days at Edgewood*, *Doctor Johns*, and *English Lands, Letters, and Kings*.

Mitch'ell, Maria, an American astronomer, was born at Nantucket, Mass., Aug. 1, 1818. She helped her father, who was a teacher, in his work in astronomy, and soon became fitted to make investigations for herself. In 1847, she received a gold medal from the king of Denmark for the discovery of a comet. She was employed in observations connected with the coast survey, and in compiling the nautical almanacs. She was the first woman made a member of the American Academy of Arts and Sciences. In 1865, she became professor of astronomy at Vassar college, holding the position until her death at Lynn, Mass., June 28, 1889.

Mitch'ell, Silas Weir, an American physician and writer, was born at Philadelphia, Pa., Feb. 15, 1829. His earliest researches were in the study of poisons, and he became an authority on the venom of snakes. His later work has been in the study of diseases of the nerves, and he stands at the head of the profession in that department of medical science. He has published, in connection with others, *Gunshot Wounds and other Injuries to the Nerves*, and *Injuries to the Nerves and their Consequences*, and has made many contributions to medical journals. In another line of literary work he has published two volumes of poems and several novels, the more notable of the latter being *Hugh Wynne*, and *The Adventures of François*.

Mit'ford, Mary Russell, an English writer, was born in Hampshire, England, Dec. 16, 1787. On her tenth birthday her father bought her a lottery ticket, which drew a prize of $100,000. This money was extravagantly spent, lasting only long enough to give her a good education. She had to write to support the family, and wrote for magazines, and plays for the stage, having earlier published a volume of poems. Her best work was the sketches she wrote of the life around her, which appeared first in the *London Magazine*, and were collected in five volumes under the title, *Our Village*. She also published, *Recollections of a Literary Life*, and a story, *Atherton*, but her fame depends upon the charming sketches. She received a pension from the government, which made her comfortable in her cottage, where she spent the remainder of her life, the center of a large circle of literary friends. She died Jan. 10, 1855. See *Life*, and *Friendships of Mary Russell Mitford*, by L'Estrange.

Mithridates (*mith-ri-dā'tēz*) **the Great,** a king of Pontus (120–63 B. C.), Armenia, and Parthia, countries in Asia Minor. He became king when about thirteen years old, near the year 120 B. C. The first Mithridatic war, as it is called, was against Bithynia, whose king was sustained by the Romans. At first, Mithridates conquered the Roman provinces in Asia Minor, and sent large armies to help the Greeks, but finally had to make peace with Sulla, giving up all his Asiatic conquests. In the second war, 83–81 B. C., Mithridates was successful, but was again defeated in the third war, which he carried on against the Romans, from 74 to 60 B. C., Pompey finally driving him to his northern territories. Here he planned revenge, but was prevented from carrying out his purpose by the rebellion of his son, when in desperation he ended his life by suicide, in 63 B. C. He was one of the strong eastern despots, well educated, speaking all the twenty-two languages in use among his subjects. He in his day made a fine collection of gems, pictures, and statues.

Mito'sis. See KARYOKINESIS.

Mivart (*miv'art*), **St. George,** an English naturalist, was born at London, Nov. 30, 1827. He was educated at Kings college, and at the age of seventeen entered the communion of the Roman church. He after this continued his studies at St. Mary's college, Oscott. For some years he practiced law, but in 1863 took his degree as a doctor of medicine at St. Mary's hospital. He also studied at Louvain and was appointed professor of biology in University college, Kensington. In both St. Mary's and Louvain he lectured upon scientific subjects. He attempted to establish harmony between the teaching of the schools and his church, but was finally excommunicated and died, cut off from the sacraments, at London, April 1, 1900. His chief publications were *Genesis of Species*, *Elementary Anatomy*, *Man and Apes*, *Contemporary Evolution*, *The Cat*, *Nature and*

Thought, *Types of Animal Life*, *The Origin of Human Reason*, etc. In the main he agreed with Darwin, although working independently of him, and at times he was considered to be radically in opposition to some of the theories of the later Darwinian school.

Mo'abites, a semitic people who lived in the country east of the Jordan and the Dead sea, their land being divided by the river Ammon. They were subject to the Jews in the time of David, but revolted about 850 B. C., and joined the Chaldees against the Jews. They are now lost in the Arab tribes of the region. Their country contains many rude stone monuments, such as have been found in the British Isles, supposed to be the altars of their worship. A large stone with an inscription of thirty-four lines, in Hebrew-Phœnician letters, was found in 1868 among the ruins of the ancient city of Dibon. It was broken by the Arabs, but subsequently was carefully put together and placed in the Louvre at Paris. It is the record of the revolt of Mesha, king of Moab, who is mentioned in 2 Kings III., against the king of Israel. See *Heth and Moab*, by Conder, and *Records of the Past*, by Neubauer.

Mobile (*mō-bēl'*), a bay on the coast of Alabama, about 30 miles long and 10 or 12

miles wide. The entrance from the gulf of Mexico is only three miles wide, and is guarded by Fort Morgan and Fort Gaines. It has also an outlet on the southwest, used by small steamers running between Mobile and New Orleans. The upper part of the bay is shallow, and is becoming more so all the time from the sediment left by the rivers flowing into it. There are three lighthouses on its shores. One of the great naval battles of the Civil war between Admirals Farragut and Buchanan was fought (Aug. 5, 1864) on the bay of Mobile.

Mobile', the only seaport of Alabama, is situated on the west side of the Mobile river, at the head of Mobile bay. It is built on a sandy plain, rising gradually from the river, with broad streets, shaded with live oaks and magnolias. It has a large cotton and timber trade, and manufactures cottonseed oil, chewing gum, cigars, and leather. Its public buildings include a city hall, market house, cathedral, and a Catholic college in the neighborhood. Mobile has been successively a French, English, Spanish, and American city. It was the capital of the colony of Louisiana under the French until 1723, when New Orleans became the seat of government. In 1763, the lands east of the Mississippi, including Mobile, were ceded to England, and in 1783 the British possessions on the gulf of Mexico were yielded to Spain, which kept possession until 1813. Population 38,469.

Mobile', a river in the southern part of Alabama, formed by the union of the Alabama and Tombigbee rivers. The name is that of the Indian tribe living in the region when first settled by whites. The river divides into two branches, the western one taking the name. These two streams after several more divisions all unite and flow into Mobile bay. The river is 45 miles long.

Moccasin (*mŏk'a-sĭn*), a very poisonous snake of the southern United States. It belongs to the rattlesnake family, but the tail is short, and ends in a horny point, instead of a rattle. The water moccasin is the most dreaded snake of the United States. The rattlesnake strikes only when disturbed, and gives warning by its rattle. The moccasin strikes without warning at anything that displeases it. It is an expert swimmer. Often it lies on bushes overhanging streams, watching for frogs and fish. It occurs from North Carolina to southern Illinois, Arkansas, and south. Its closest relative is the copperhead, or upland moccasin, commonly called the cotton-mouth.

The name also of a shoe (Algonquin *mok-i-sin*) worn by the Indians of North America. It is made, sole and upper, of deerskin, or other soft leather, and is ornamented on the top with beads of various colors.

Mockingbird (*mŏk'ing-bird*), a singing bird of the thrush family closely related to the catbird. There are several species found in South America, the West Indies, and the United States. That of the southern United States is best known. It ranges across the country to California and south into Mexico. In the summer, it is found in small numbers as far north as Massachusetts. It is about the size of a song thrush, with the upper parts dark brownish ash in color, the wings and tail nearly black, and the under parts brownish white. It is a fine singer, and during moonlight nights while nesting, will sing all night. Its natural song contains many notes similar to those of other birds, though its powers as an imitator have been exaggerated. Besides

imitating the sweet tones of the wood thrush, it whistles, makes sounds like a creaking wheelbarrow, the barking of a dog, the squeak of a hurt chicken, etc.

Modena (*mŏd'ā-nȧ*), a city in northern Italy, capital of the province of the same name, twenty-three miles from Bologna. It is surrounded by walls, which have been made into fine walks. The square tower of the Gothic cathedral, begun in 1099, is one of the great towers of Italy. The palace, built in the 17th century, contains the Esté library of 90,000 volumes, and a large collection of the works of Guido, Correggio, the Caracci, and other Italian masters, among them a reclining figure of Cleopatra by Canova. The University of Modena, one of the most famous in Italy, founded in 1678, has an academy of science and art, an observatory, a botanic garden, and a military school. It has forty-five teachers and 435 attendant students. The trade of Modena is in farming products, and its manufactures of silk, leather, cast metals, and vinegar. Modena was first an Etruscan city, and was taken by the Gauls, Romans, Goths, and Longobards. Constantine the Great destroyed it; Charlemagne made it the capital of a line of counts; and the Esté family ruled over it from 1288. The duchy of Modena became a part of the Italian kingdom in 1860. Population of the city 68,195.

Modjeska (*mod-jes'kȧ*), **Helena,** a Polish actress, was born at Cracow, Austria, Oct. 12, 1844. From 1868 to 1876, she was the first actress of Warsaw, where she made the plays of Shakespeare popular. She tried farming in California, but failing in her enterprise, returned to the stage in 1877, and won a complete success in San Francisco, though she acted in English, a language she had used for only seven months. She is acknowledged to be one of the best of modern actresses, especially as "Juliet," "Rosalind," "Mary Stuart," "Camille" and "Cleopatra," in which characters she has obtained her greatest reputation, both in the United States and in Great Britain.

Modocs (*mō'doks*), a tribe of American Indians, formerly living in northern California, near Lake Klamath. Their houses were pits, roofed with wooden slabs, and covered with earth. They had several contests with the white settlers, and finally in 1855, 41 out of 46 of their warriors were treacherously murdered by the whites, when invited guests at a feast. This treachery they never forgot, and became bitter enemies. In 1864, after many contests, they ceded their lands to the United States, and agreed to go on a reservation, but the reservation was not given them until 1871, and they lived on the Klamath lands, where their provisions were destroyed, they were cheated out of government supplies, and harassed by the Klamaths. A part of the tribe, under a chief called Captain Jack, returned to their old home, but were ordered away by the United States troops. They repulsed the troops, and retreated to what is known as the lava beds in the mountains, in the fall of 1872, where they defended themselves against repeated efforts to dislodge them until the summer of 1873. Their chiefs were executed, and the rest of the band were carried to the Indian territory. Those who had not taken part in the war remained at the Klamath agency.

Moff'at, Robert, a Scottish missionary, was born in East Lothian, Scotland, Dec. 21, 1795. In 1816, he sailed for South Africa, under the London Missionary society, and began his work in Great Namaqualand, in the country of a chief called Afrikaner, who had been a terror to all the region until he came under the influence of Christianity. He opened mission stations, printed the Bible and other books in the native language, and made the whole region a center of Christian light. From 1838 to 1843, he was in England, publishing his *Missionary Labors in South Africa*, and telling to crowds of hearers his adventures and work in that land. He returned with other missionaries, remaining until 1874, when after 54 years of missionary work he once more made England his home, where his labors were honored by a gift of $25,000 and a public reception in London. He died Aug. 8, 1883. His influence led Livingstone, whose wife was Mary, the daughter of Robert Moffat, to Africa.

Mogul (*mō-gul'*). See INDIA.

Mohacs (*mō'hȧch*), a town of southern Hungary. It is a station for steamboats on the Danube and has considerable trade in wine, coal, and timber, mostly with Vienna. It is noted as the scene of a great battle, fought Aug. 29, 1526, between 200,000 Turks under Soliman the Magnificent, and 25,000 Hungarians under their king, Louis II. The Hungarians were defeated, losing their king, seven bishops, a large number of nobles, and 22,000 men. A second battle was fought here in August, 1687, when the Turks were defeated by the Hungarians, losing 20,000 men. Population 15,000.

Mohammed (*mo-hăm'ed*), or **Mahomet** the founder of the Mohammedan religion, was born at Mecca, Arabia, about 570 A. D. His early life was spent in poverty, partly as a shepherd, until acting in some capacity, perhaps as a camel-driver, in the caravan of a rich widow, Khadija. She, though fifteen years older, became his wife. He spent his time after this, while a merchant, largely in lonely meditation. Christianity and Judaism both prevailed in the region, and the ancient pagan religion had lost its hold on the people. Missionaries from Arab tribes began preaching at Mecca and Medina, and were the forerunners of Mohammed. His first religious revelation, as he called it, received from the angel Gabriel, when he was forty years old,

was a command to preach a new religion. These revelations were always attended by spasms, something like fits of epilepsy, which were believed by his enemies to be the work of devils. The revelations continued at intervals and were collected and written down after his death, forming the Koran or sacred writings of this religion. His first revelation, when told to his near friends, brought him only ridicule, but at the end of four years he had forty followers. The command was then given him to come forward publicly as a preacher, which he did, exhorting to a moral life, and a belief in one God, whose prophet he was. At first he was looked upon as a harmless maniac, but as the number of his followers increased, and his attacks on the old religion became more severe, the people of Mecca rose against him. His uncle, though not believing in him, protected him, carrying him to a strong castle, where he stayed three years. His whole clan was outlawed and his followers suffered persecution, a hundred of them fleeing to Abyssinia. After his return to Mecca he lost his wife and his uncle, and was reduced to poverty. He made several new converts, from Medina, increasing their number with each pilgrimage that was made to Mecca, until, when they numbered seventy, he decided to flee from Mecca to the friendly city of Medina, which he reached in 622 A. D. This flight, or Hegira, is the beginning of the Mohammedan era. His position was at once changed, and from being a despised maniac, he became the ruler of the city and the head of two powerful Arab tribes. His most important act at this time was the giving permission to carry on war against the enemies of the new faith. Victorious in the first battle against the Meccans, adventurers flocked to his standard, and he carried on the war with the Arab tribes successfully, yet with great cruelty. He finally made a ten years' peace with the Meccans, which allowed him to send his missionaries through Arabia, and he soon made his first pilgrimage to Mecca with 2,000 followers. From this time his power increased rapidly. He marched to Mecca with an army of 10,000 men, and was proclaimed chief. Tribe after tribe sent messengers to do homage to him, either as the Prophet of God or the prince of Arabia.

His last pilgrimage to Mecca was made in the tenth year of the Hegira, and at that time he ordered the ceremonies of the great pilgrimages, which are still observed. His last sickness occurred in the house of his favorite wife Ayesha, who was but one of many whom he married after the death of Khadija. He called for writing materials, probably to indicate his successor, but Omar, his most influential friend, prevented their being given him, fearing he would appoint Ali, while he himself wanted Abu Bekr. Mohammed died at Medina, Arabia, June 8, 632, in the eleventh year of the Hegira. Abu Bekr said to the gathered crowd, who would not believe in his death: "Whoever among you has served Mohammed, let him know that Mohammed is dead; but he who has served the God of Mohammed let him continue in his service, for he is still alive and never dies." The tomb of Mohammed, in the house where he died, is now part of the mosque at Medina.

The religion of Mohammed recognized the one God, the creator of all things; Adam, Noah, Abraham, Moses, Jesus, and Mohammed as successive prophets, who proclaimed new laws, which did away with all that had gone before; it recognized also the resurrection from the dead and a final judgment and future rewards or punishments. It commanded prayer, almsgiving, fasting, and pilgrimages. It forbade the drinking of wine, all games of chance, the use of blood of swine or animals dying from disease as food, and the worship of idols. It allows polygamy, though limiting the number of wives to four. Every Mohammedan prays five times a day, and the hour for prayer, called by the muezzin, is announced by this officer, from the minarets of the mosques. When praying their faces are turned toward Mecca. The Koran, the sacred book of the Mohammedans, is made up of the "revelations" made to Mohammed, which he had written down, but which were not collected until after his death. It comprises some 114 chapters, and the contents are drawn from the ancient Arab traditions, the Old and New Testaments, the Talmud of the Jews, and later writings. Eighty years after the death of Mohammed, Islam, as the Mohammedans call their religion, ruled in Arabia, Syria, Persia, Egypt, a part of Africa and Spain. Two hundred millions of the human race embrace it to-day. Its conquests in modern times have been in Africa, but its power has declined in other countries. See *Mahomet*, by Washington Irving; *Life of Mahomet*, and *Mahomet and Islam*, by Sir W. Muir.

Mohammed Ali or **Mehemet** (*mā'he-met a'lē*), viceroy of Egypt, was born at Kavala, Macedonia, in 1769. He served in the Turkish army in the war against the French in Egypt, and became one of the most popular of military leaders. After the French were driven out, he fought with the Turks against the Mamelukes, and finally was made pasha, or chief ruler, by the people of Cairo, and confirmed in his power by the sultan of Turkey. After many contests with the Mamelukes, aided during part of the time by the British, he enticed, in 1811, a large number into the city of Cairo and treacherously murdered 470 of his guests, following it by a general massacre of the Mamelukes throughout the country. In 1816, he conquered part of Arabia, and, in 1820, Nubia and a part of the Sudan. His armies, under his son Ibrahim, invaded Syria, which Turkey ceded to Egypt on condition of tribute. His conquests were checked

when within six days' march of Constantinople, by the allied forces of the European powers. In 1840, he was compelled by Great Britain, Russia, Austria, and Prussia to accept terms of peace, by which Egypt was secured to him and his descendants, on condition of yielding Syria to the sultan and paying him a quarter of his revenues as tribute. He introduced many modern improvements into Egypt, maintained a standing army, and increased irrigation, the cultivation of cotton, and manufactures. He died at Cairo, Aug. 2, 1849.

Mo'hawks, a tribe of American Indians, one of the Five Nations or Iroquois. They were friends of the Dutch in New York, and afterward of the English, and during the French and English wars they did good service in Canada. In the Revolutionary war, under Brant, they fought with the English and massacred American settlers. Since 1784, they have been settled in Upper Canada (Ontario). Brant translated the prayer book and a part of the Bible into the Mohawk language, and there is also a dictionary and a grammar of the language. See *History of the Five Indian Nations*, by Colden; *Brant and Red Jacket*, by Eggleston and Seelye.

Mohicans (*mō-hē'kanz*), or **Mohegans** (*mō-hē'ganz*), a tribe of Indians belonging to the Algonquin family, who were living on the Hudson river when that region was settled by the Dutch. They fled to Connecticut, being driven there by the Mohawks. They joined the English against the French, but during the Revolution sided with the Americans. They have since been scattered, some settling at Oneida, N. Y., some moving to Wisconsin, and a small remnant going to Kansas. They have mostly given up their language, and have become citizens. The name has been made famous by Cooper's novel, *The Last of the Mohicans*. See *Indian Mission at Stockbridge*, by Jones; *Indian History for Young Folks*, by Drake.

Moldau (*mol'dow*), the principal river in Bohemia, rises 3,870 feet above the sea, in the southwestern part of the country, and flows first southeast and then north, until, after a course of 278 miles, it joins the Elbe about 20 miles north of Prague.

Molda'via. See RUMANIA.

Mole, a burrowing animal with a barrel-shaped body and sharp snout. The front paws are broad and stout and well fitted for digging. Moles are covered with a dense velvety fur of a dark color. As they lead an underground life, their eyes are minute or rudimentary, and often covered with skin. They are found in both the Old and the New Worlds in the northern hemisphere. The common English mole disfigures lawns, pastures, and gardens extensively, by the ridges and furrows it makes hunting after food, but as it feeds on injurious larvæ and insects, it compensates for the damage. The fortress of the mole is complicated. In little hillocks of earth, called mole-hills, there is constructed a central chamber, surrounded by two ring-like galleries, one above the other. These circular galleries are connected by vertical passages, and the upper one has five openings into the central cavity. From the lower gallery, about nine alleys lead off in different directions toward the feeding-grounds. They feed mainly on earthworms and also eat insects, larvæ, field mice, etc. Occasionally, on fine summer nights they issue from their burrows. The star-nosed mole is peculiar to the northern United States, and to British America. It has arranged around its snout twenty cartilaginous rays which contain organs of touch.

Mole-Cricket. See CRICKET.

Molecule (*mŏl'e-kūl*) is a word which is employed in science with two rather different meanings. Experiment has shown that matter is not continuous, but is probably made up of very small particles. Accordingly, the chemist uses the word *molecule* with considerable accuracy to mean the smallest portion of any kind of matter which can exist alone and yet preserve the properties of this particular kind of matter. Thus the smallest portion of table salt which can exhibit the properties of table salt must contain still smaller parts of sodium and of chlorine. These smaller particles of which the molecule is made up are called *atoms*. But even when a body is made up of atoms of one kind, these atoms rarely remain uncombined, but unite with each other to form molecules. Thus hydrogen gas is composed of molecules made up of two atoms of hydrogen. Remsen distinguishes between molecules and atoms as follows: "Atoms are the indivisible constituents of molecules. They are the smallest particles of the elements that take part in the chemical reactions, and are, for the greater part, incapable of existence in the free state, being generally found in combination with other atoms, either of the same kind or of different kinds." (*Chemistry*, p. 74). In chemistry, the molecule of a compound consists of atoms of a different kind, while the molecule of an element consists of atoms of the same kind.

In physics, the word *molecule* is used more loosely, often, to mean the smallest particle of a substance with which we are dealing, whether it be made up of one or more atoms, and whether these atoms be of the same or of different kinds. Thus there is reason for thinking that the diameter of a hydrogen molecule is something like 5.8×10^{-8} centimeters, while the diameter of a carbon dioxide molecule is larger, namely, 9.3×10^{-8} centimeters. Molecule is used in this sense in the classical illustration given by Lord Kelvin, that a drop of water magnified so as to appear the size of the earth would be made up of molecules about the size of cricket balls.

Too little is yet known about molecules even to define exactly what is meant by "the size of a molecule." See ATOM. HENRY CREW.

Mollere (*mo-le-êr'*), **Jean Baptiste Poquelin,** a French dramatist, was born at Paris, Jan. 15, 1622. His father's name was Poquelin, the name Molière being taken for the stage. He began as a theatre manager, failing in Paris, but successful in the provinces, returning to Paris in 1658, where he organized a regular theatre. He wrote several of his comedies while traveling through the country with his theatrical troupe. He depended largely for his tragedies, as a theatre manager, on Corneille and Racine, and in his comedies and farces borrowed from Spanish and Italian literature, owing to the haste with which many of them were written for use in his theatre. From the year 1659, when the first of his great comedies appeared, until 1673, not a year passed without adding one at least to the number of these immortal works. He attacked with his satire, religious hypocrisy, in *Tartuffe*, which, in consequence, was forbidden the stage for five years; the vanity and follies of women; the frivolity of the nobles, and the pretensions of the learned classes, especially the doctors. His wit, his satire, and his power over language, place him in the highest rank of French writers; and his plays have held their place on the stage for two hundred years. His greatest works are: *The School for Wives*, *The Misanthrope*, *Tartuffe*, *The School for Husbands* (*L' École des Maris*), *The Physician in Spite of Himself* (*Le Medecin Malgré Lui*), *The Imaginary Invalid* (*Le Malade Imaginaire*), and *Learned Women*. He died at Paris, Feb. 17, 1673. A century after his death his bust was admitted to the French academy, which had never received him as a member because he would not give up his profession.

Moline (*mō-lēn'*), a city of Illinois, in Rock Island county, on the Mississippi river, 179 miles west of Chicago. It is separated from Rock Island by a narrow channel, which is used as a water-power. It is a manufacturing city, with numerous mills and factories. Population 17,248.

Mol'lusks, a sub-kingdom of animals, with a soft body, as snails, clams, and others. The body is not jointed as in the earthworm and crayfish. Mollusks usually possess a shell, but there are some naked forms. They live on land, and in both fresh and salt water. Some mollusks have a larval form, similar to that of some worms, and this serves to connect the two groups. The group is a large one, and is divided into classes as follows: *Gasteropoda*, those like snails, crawling on a broad fleshy foot. The class contains common snails, slugs, and many sea shells, like whelks, etc. (See SNAIL, and LIMPET.) Land snails, feeding on plants in damp districts, are common in many sections of the United States and other countries. In the Philippines are many tree snails. Pond snails are abundant in still water; there are flattened forms, long sharp-pointed ones, and others showing gradations between the two. *Lamellibranchiata*, mollusks with gills like plates or lamellæ, represented by clams, oysters, and mussels (which see). Their shells have two valves, and they are, therefore, called bivalves. *Cephalopoda*, mollusks with processes called arms or feet clustered around the head, and, therefore, named the head-footed. The arms are provided with sucking disks. (See CUTTLEFISH, SQUID, NAUTILUS, etc.) *Amphineura*, containing the Chitons, and *Scaphopoda*, represented by the elephant tooth shell, are two classes of less popular interest. The mollusks are represented by twenty thousand living and nineteen thousand fossil species. See Woodward's *Manual of the Mollusca* (3d ed., 1875).

Molly Maguires (*mol'-i-ma-gwirs'*), an Irish secret society which existed from 1867 to 1877 in the coal regions of Pennsylvania. The name came from Ireland, where a band of "ribbon men" carried on their outrages by night, disguised as women. The society in Pennsylvania attempted to obtain political power by a system of terror, committing murders when opposed. A number of the leaders were convicted and executed, by the aid of a detective who acted for three years as the secretary of one of the branches of the society.

Moloch (*mō'lok*) or **Mo'lech,** the name of a heathen god worshiped in Judæa. He was once called the god of the Ammonites, and his worship was probably derived by the Jews from some of the neighboring tribes. The kings Ahaz and Manasseh are spoken of as making their children pass through the fire of Moloch. The victims were slain and afterward burned on a funeral pile called "Tophet," in the valley of Hinnom, near Jerusalem. The story of an image of brass, heated red-hot in which the children were burned, is an invention.

Moltke (*mōlt'ke*), **Helmuth von** Count, a distinguished German field-marshal, was born Oct. 26, 1800, at Mecklenburg-Schwerin. His father being a Danish officer, he was sent to a military school at Copenhagen, and entered the Danish army as a lieutenant, but left it for the Prussian service. He spent considerable time in the study of military tactics and foreign languages, and was appointed on the staff of Prince Frederick William. Traveling in Turkey on a leave of absence, the

COUNT VON MOLTKE.

sultan retained him as military adviser, and gave him the work of remodeling the Turkish army. He was chief of the general staff of the army in Berlin from 1858 to 1888, and reorganized the Prussian army. He also made plans for coast defenses, and the creation of a navy. His great powers as a military leader were shown in the war with Denmark in 1863, with Austria in 1866, and with France in 1870. He was called "The Silent," from his great modesty and reserve. He wrote *Letters from Turkey*, *The Campaign in Turkey*, *The Italian Campaign of 1859*, and *Letters from Russia*, while the *History of the German and French War*, by the general staff, was written under his direction and much of it by him. His ninetieth birthday was celebrated with much honor by the emperor and the German people. He died at Berlin, April 24, 1891. See *Life* by Müller, translated by Pinkerton.

Moluccas (*mō-luk'ăz*), called also **Spice Islands**, a division of the Malay archipelago or Dutch East Indies. It includes most of the islands between Celebes and New Guinea, east and west, and between Timor and the Philippines, north and south. It is divided into the Northern Moluccas and the Southern Moluccas. The northern group runs from north to south, is surrounded by deep water, includes ten or a dozen large islands with smaller ones, and has a population of about 60,000. The largest island is Jilolo, while the smaller islands of Tidor and Ternate have been the most important. They were occupied by civilized tribes of Malays, who ruled the ruder tribes on the surrounding islands, and were later the seats of the powerful Mohammedan sultans; and now, as the seat of the Dutch government or residency, Ternate has most of the trade of the Northern Moluccas, exporting spices, tortoise shell, beeswax, and birds of paradise. The Southern Moluccas are separated from the northern group by a very deep ocean chasm, and are connected by a shallow ocean bed. There are two large islands, three or four smaller ones, and several clusters of small ones, covering about 43,864 square miles, and having a population of 400,000. The town of Amboyna, the capital of the Dutch possessions in the Moluccas, carries on a large trade in cloves, 500,000 pounds being raised in some seasons in the clove gardens of the government. Banda, the third Dutch residency, is the home of the nutmeg, which grows on the slopes of the volcanic islands. Besides nutmeg and mace, it also exports sago and cocoanuts. The region of the Moluccas is volcanic, and there are still several active volcanoes, from one of which, Api, in Banda, there was a terrible eruption in 1825. The climate is tempered by the ocean breezes, and by the height of the islands, some of them rising 8,000 or 10,000 feet above the sea. Spices grow abundantly, but were rooted out by the Dutch government from all the islands except the Banda group and Amboyna, to give the latter a monopoly of the trade. The animals are curious, such as the flying opossum, the bird of paradise, the mound-building bird, the long-armed beetle, most gorgeous butterflies, and beautiful sea anemones, shells, and corals.

Mommsen (*mom'sen*), **Theodor**, a German historian, was born at Garding, Schleswig, Nov. 30, 1817. He spent three years traveling in France and Italy, studying Roman inscriptions, edited a newspaper in Schleswig, and held a professor's chair at Leipsic, that of Roman law at Zurich, and the same professorship at Breslau, and that of ancient history at Berlin. His large library was burned in 1880, and a new one was presented him by his English students. He edited, with others, several historical works, and wrote a number on Roman law, Roman coins and kindred subjects, making him famous as one of the greatest scholars of the age. His great work, a *Roman History*, in three volumes, has passed through five editions, and been translated into French and English. From 1873 to 1882, he was a member of the Prussian chamber of deputies, when he acted with the national Liberal party.

Monaco (*mon'ă-kō*), a small principality on the Mediterranean, nine miles from Nice. It covers eight square miles, and consists of a rocky promontory, on which the city of Monaco is built, and a small strip of coast. Here, within the petty state, is the great gambling town and casino of Monte Carlo. It has belonged to the Grimaldi family for over 900 years. They have several times put their country under French protection, and in 1859 the whole region belonged for a short time to Victor Emmanuel. The owner at another time sold a part of his dominions, including Mentone, to Napoleon III. for $200,000. His capital is now under French protection. The climate is mild, and palms, aloes, and other southern plants are abundant. Population of the entire principality 13,304.

Monastir (*mŏn-as-tēr'*), also called **Bitolia**, the second city in Turkish Macedonia, is situated in a broad mountain valley, ninety miles northwest of Salonica. It manufactures carpets and silver filigree, and trades in corn and other farm products. The Turks have made it the head of an army corps, as it is an important military point. Its ancient Greek name was Pelagonia. The Albanian beys were massacred here in 1833. Population 45,000. Monastir is also a vilayet, or province, in European Turkey, area 10,690 square miles; population 847,400.

Mon'ey is the name given to those substances which are used to facilitate commercial exchanges and to serve as a measure of values. Nearly all metals have been so used at some time, or by some nation, but

[illegible] have been found the most [illegible] for general purposes. [illegible] and even [illegible] have been accepted [illegible] civilized nations, [illegible] have frequently [illegible] The value of [illegible] like other values, [illegible] the supply [illegible] at the time [illegible] and the [illegible] amount of commercial [illegible] which money is [illegible] the problem so many other [illegible] that no simple theory can be [illegible] account for all the [illegible] The use of money raises com- [illegible] barter to a [illegible] If the world had [illegible] the seller could only sell [illegible] with a desire also [illegible] which the first [illegible] But by [illegible] can be sold or any- [illegible] at any time, by persons [illegible] to facilitate the trans- [illegible] The supply of gold being limited, [illegible] has always been held [illegible] than other [illegible] depending upon the [illegible] and the size of the trans- [illegible] In deals involving [illegible] it would seem necessary [illegible] some form of money in which the [illegible] might be easily transferred. In [illegible] money was issued by private in- [illegible] in order to insure inspection [illegible] this duty and [illegible] has now been assumed by the state. [illegible] a charge is made by the [illegible] for transforming bullion into [illegible] the metal is converted [illegible] at little expense to the owner, [illegible] ground that the cost is small [illegible] according to the state, [illegible] the increase of the stock of [illegible] The history of coinage in the [illegible] is of surpassing interest, and [illegible] attention to the student. It is [illegible] to give them due attention in so [illegible] work as this; but it may be noted [illegible] the relative value of gold and bullion has in- [illegible] from $15.93 in 1873, to [illegible] and that of silver from $1.15 [illegible] $1.34 in 1900. The money of all [illegible] circulation in the United States has [illegible] from $18.10 per capita in 1860, to [illegible] The per capita circulation of [illegible] the world is estimated at $5.00 and [illegible] at $3.00. The coinage of gold and [illegible] the world averages at present, about [illegible] annually, according to the reports [illegible] and by the national government.

[illegible] a city near Appomattox, situated [illegible] and south of China proper, [illegible] of Manchuria and east of eastern Turkestan. It is in the main a wide waste, comprising the great desert of Gobi. Its area is 1,288,000 square miles, with an estimate population of 2,000,000.

Mongols (*mong'gols*), an Asiatic race, constituting one of the large divisions of mankind, including the Mongols proper, known as East Mongols and West Mongols and Bariats, and the Tartars, who form a distinct branch. The Kalmucks belong to the West Mongols. Mongolia, inhabited by the East Mongols, is a part of the Chinese empire lying south of Siberia, and shut in by mountain ranges. The people lead a wandering life, dwelling in tents, and having flocks of sheep and herds of horses, cattle, camels, and goats. They are mostly Buddhists in religion, and fond of making long pilgrimages. There are about 2,000,000 of them under Chinese rule. The Western Mongols have mingled with their Turkish neighbors so that it is difficult to number them. They are found in Russia, Astrakhan, Turkestan, Bokhara, Samarcand, and the Crimea. The history of the Mongols begins with Genghis Khan, born about 1160, who united the different tribes into one nation and led them out to conquest. They overran Tartary, a large part of China, Persia, Russia, and Afghanistan. Under his sons and their successors, other portions of China were conquered, the caliphs of Bagdad overthrown, and Europe invaded as far as the Danube, making the Mongol empire, at its height, the greatest the world has known. Kubla Khan, the grandson of Genghis Khan, established the first Mongol dynasty in China, which was finally overthrown by the Chinese in the 14th century. The Mongol kingdom, divided in the 13th century, was united again in the 14th century under Tamerlane, but after his death lost its power, until in the 17th century it became a part of the Chinese empire. The Mongolian language belongs to what is called the Turanian family. There is very little extant literature, what they possess being mostly translations from Chinese religious works; the original works being mainly accounts of the deeds of Genghis Khan and Tamerlane. See *History of the Mongols*, by Howorth; *Among the Mongols*, by Gilmour.

Monitor, the name given to a kind of warship first used in the Civil war. It was a wooden ship covered with plates of iron, carrying in the center a revolving tower or turret, in which the guns were placed. The first one used was made by Captain Ericsson in 100 days, and was engaged in the naval battle with the confederate ship *Virginia*. The success of the *Monitor* produced great excitement in Europe and made a revolution in the construction of naval vessels. England immediately experimented with this style of warship, changing a wooden vessel into an ironclad monitor, which was considered the most formidable ship in the navy. Improvements were made from time to time, until the

greater part of naval vessels are now made upon this principle and known as monitors or "ironclads." See NAVY.

Monk (*mungk*), **George,** Duke of Albemarle, an English general, was born in Devonshire, England, Dec. 6, 1608. His first services in the army, at Cadiz, Rochelle, consisted of nine years in Holland, and in wars against the Scotch and the Irish, ended in 1644, when he was taken prisoner by Fairfax and kept in the Tower of London for two years. He was freed by agreeing to the covenant. He was major-general at Ulster, and Cromwell left him to finish the conquest of Scotland, and in 1654 he was appointed governor of the country, a position he filled well for five years. At the death of Cromwell, while everything was in confusion, he marched to London with 6,000 men, and entered the city without opposition in February, 1660. Every party wanted him, and felt that the fate of the country lay with "Old George." His own wish was to bring back the Stuarts, and he found the nation with him. He worked slowly and with circumspection; freed the parliament from the power of the army, admitted members that had been excluded, and brought about the election of a new parliament, and on May 23, 1660, he welcomed Charles II. at Dover. He was rewarded with high offices, and made duke of Albemarle, but soon retired from political life. As governor of London, at the time of the plague, he stayed at his post and helped bravely. He died Jan. 3, 1670. "A man capable of great things, but possessing no greatness of soul," is the judgment of Guizot. See *Life*, by Guizot, and also the one by Corbett.

Monkey (*mŭn'kĭ*), a word loosely applied to apes, baboons, Old and New World monkeys, marmosets, and lemurs. Here it is, for convenience, restricted to the smaller forms living on trees, and usually having long tails. This separates them from the baboons and higher apes on the one hand, and the lower lemurs on the other, all of which are noticed alphabetically. The New World monkeys have nostrils wide apart (*Platyrrhini*), and most of them have long tails used for grasping. They inhabit the forests traversed by the Amazon and the Orinoco, and extend north to Panama. Ten species live north of this in Central America, and one—the spider monkey—extends its range into Mexico. The howling monkeys have a resonance chamber at the top of the windpipe, and, night and morning, they make the forests resound with their hideous howling. They cannot be tamed. The monkeys usually seen in captivity, from South America, are marmosets and monkeys of the genus *Cebus*. The marmosets are the smallest monkeys, not much larger than squirrels, and are usually made a separate group. The spider monkeys have slender bodies, long, angular limbs, and very long tails, which are used as a fifth hand. The Old World monkeys are entirely distinct. Their nostrils are close together (*Catarrhini*) and the tail, when present, is not used for grasping. The macques, inhabiting India, Thibet, Malay archipelago, Philippines, etc., are often seen in menageries. Throughout Africa are found numerous troops of monkeys with slender bodies, like the green monkey. They live on trees and have long tails. The Catarrhini include also baboons and higher apes, but these are treated separately. See APE, BABOON, LEMUR, and MARMOSET.

Mon'mouth, Battle of, an engagement between the English forces under Clinton, and the American forces under Washington, at Freehold, Monmouth county, N. J. It was Washington's first battle after the dreary winter at Valley Forge. General Lee was in charge of the advance, which was thrown into confusion and began a retreat. Washington hurried to the front, reproving Lee sharply, and rallied the fugitives. Tradition says that this was the only time that Washington was known to swear. The Americans held their ground, and Clinton retreated in the night. Lee was deprived of his command for a year by court-martial.

Mon'mouth, James, Duke of, was born at Rotterdam, Holland, April 9, 1649. He was thought to be a son of Charles II., and as such was made duke of Monmouth, and wedded to a rich heiress. In spite of his profligacy, he became the idol of the people, thanks to his beauty and winning manners, his royal tours through the country, and his humanity toward the Covenanters at Bothwell Bridge, in 1679. His share in what is known as the Rye House Plot, in 1683, was discovered, and he fled to Holland. After the death of Charles, he returned to England, with eighty-two followers, landing June 11, 1685. He claimed the throne, attacked the king as a murderer and Catholic, and had himself proclaimed as James II. Gathering a force of about 3,000 men, mostly peasants and miners, he risked a battle with the king's troops at Sedgemoor. He was defeated, losing nearly half his army, and was captured when fleeing, disguised as a shepherd. His tears and pleadings, and even the promise to change his religion, were of no avail with the king, and he was beheaded at London, July 15, 1685. See *Life*, by Roberts.

Monocotyledons (*mŏn'o-kŏt'i-lē'dŭns*), plants forming one of the two great groups of angiosperms, containing about 25,000 recognized species. The name comes from the fact that the embryo develops a single cotyledon. The other features which distinguish the group in general are the structure of the stem, in which the woody bundles are scattered, as in the common corn; the parallel-veined leaves, and the members of the flowers in threes. Monocotyledons were once

called "endogens," an antiquated name which has been entirely abandoned. Prominent monocotyledonous groups are as follows: "Pond-weeds," among which are the numerous more or less submerged aquatics and closely-allied forms, and related to which are the well-known forms of arrowleaf and cattail flag; "grasses," one of the largest and most useful groups of plants, much confused with the nearly allied sedges; "palms," a group of tree monocotyledons very characteristic of the tropics; "aroids," an immense tropical group represented in temperate regions by skunk cabbage and Jack-in-the-Pulpit, and in cultivation by the better known calla lily; "lilies," associated with which are the numerous amaryllis and iris forms; "orchids," which in number of species are most numerous among the monocotyledons, and favorites in greenhouse cultivation on account of their brilliant color and bizarre forms.

Monongahela (*mō-non'ga-hē'la*), a river, one of the sources of the Ohio, rises in West Virginia, flowing north into Pennsylvania where it unites with the Allegheny at Pittsburg and forms the Ohio. It is 250 miles long, and is navigable for about 80 miles for large boats. The Cheat river and the Youghiogheny are its chief branches. Here, on the banks of the river, near Pittsburg, was fought, July 9, 1755, a battle between the French and the Indians and the British and colonial troops under Braddock. The latter were beaten.

Monop'oly, a term used to indicate the sole right to sell or trade in any article, given to a single person, or to a group of persons. In early times this right was often granted by government, as in the time of Queen Elizabeth, salt and coal were articles whose sale was thus limited; and one of the greatest monopolies the world has ever known, the East India company, received its charter at that time. These government monopolies were opposed by the English people, and finally put an end to. Monopolies, under their modern form of trusts, combines, syndicates, or unions, are the same in principle, an effort to do away with competition and give to one set or class of persons the sole right of selling or trading in an article. These combinations are effected by the use of capital, which is employed to drive out of business all small dealers. The Standard Oil company and the Reading Coal "combine" are well-known instances of great American monopolies.

Monroe', James, the fifth President of the United States, was born in Westmoreland county, Va., April 28, 1758. He entered William and Mary college, but soon left to join the army under Washington. He was in several battles, was wounded at Trenton, and became lieutenant-colonel and military commissioner. In 1782, after studying law with Jefferson, he became a member of the Virginia assembly and was sent the next year to congress. Here his services were influential in bringing about the conventions at Annapolis and Philadelphia, where the constitution of the United States was framed, which, however, he opposed in the Virginia convention, siding with Patrick Henry and other States' Rights men. He was in the United States senate from 1790 to 1794, and became minister to France from 1794 to 1796, when he was recalled because of his too open expressions of sympathy with the revolution. His former opposition to Washington and this treatment induced him to publish an attack on the government, which made him the favorite of the Democratic party. He was governor of Virginia for three years, and then was sent by Jefferson to France, where, with Robert Morris, he effected the Louisiana purchase in 1803. His efforts for a cession of Florida by Spain were unsuccessful, and the treaty with England obtained by him failed to provide against the seizing of American sailors. In 1811, he was again governor of Virginia, and secretary of state under Madison until 1817. In 1816, he was elected President of the United States, and re-elected in 1820. The most popular measures of his administration were the obtaining of Florida from Spain (1819), the settling of the slavery question by the Missiouri Compromise, the recognition of the independence of the Spanish American republics, and the announcement of what is known as the Monroe Doctrine. In a message to congress approving the bill which recognized the South American republics, Monroe declared that "the American continents are not to be considered as subjects for colonization by any European power." This declaration, known as the "Monroe Doctrine," has ever since held a place as well in the diplomacy as in the political creed of the nation. After his retirement to his home in Virginia, he became involved in debt, but found a home with his son-in-law in New York, where he died, July 4, 1831. See *Life*, by Gilman, in the "American Statesmen" series.

JAMES MONROE.

Monsoon, a term meaning a "set time or season," formerly used to indicate the winds prevailing in the Indian ocean, blowing from the southwest from April to October, and from the northeast from October to April. The word is used now of all winds that are regular, returning with the seasons. The prevailing winds of North America are largely of this class, and there are monsoons in Aus-

tralia, on the coasts of Brazil, Peru, and North Africa. See WINDS.

Montagu (*mon'ta-gū*), Lady **Mary Wortley**, was born about 1689 in Nottinghamshire, England. When only eight years old her father introduced her to the famous Kit-Cat club, of which she became a member. After her marriage her husband's public position brought her into court society in London, where she was celebrated for her wit and beauty, and numbered among her friends Addison, Pope, and other literary men of the time. In 1716, her husband was English ambassador at Constantinople, and during her life there of two years, she wrote the *Letters* that have have made her famous, addressing them to her sister, to Pope, and other friends. They are descriptions of eastern life and manners. She became convinced of the benefit of inoculation for smallpox while abroad, and introduced it into England, trying it first on her own son. She died Aug. 21, 1762. See *Life*, in the edition of her works by Wharnecliffe.

Montaigne (*mon-tān'*), **Michel Eyquem de**, a famous French essayist, was born in 1533, in Perigord, France. His father had peculiar ideas of education, and put them in practice in his son's case. He was nursed by a poor woman in a village, that he might learn simple habits of living and sympathy with the poor. That his boyhood might be made as happy as possible, he had him wakened every morning by the sound of music. As he must learn Latin, then the necessary foundation of all education, he had him taught it in the easiest way, by conversation, and until he was six years old he understood no other language. His father sent him to school at six, making various arrangements to carry out his plans of education. He studied law, and became a city counselor, holding the office for thirteen years. His first literary work was a translation of a Spanish *Natural History*. On the death of his brothers, he succeeded to the family estate, and here began his famous *Essays*, which were written simply because he felt the need of occupation. These essays, written apparently without any plan, inspired by the caprice of the moment, touching upon his daily life, his habits, tastes, and thoughts, on all kinds of subjects, have held the attention of a large class of readers, of all kinds and sorts, for 300 years. The circle of admirers widens every year, and is almost equal to that composed of the followers of Shakespeare. He died in 1592. See *Representative Men*, by Emerson; *Montaigne*, by Collins.

Montana (*mŏn-tă'na*), one of the northwestern states of the Union, is the third in size, coming next to Texas and California, covering a land surface of 145,310 square miles, being larger than the British islands. The Rocky mountain region in the western part includes one-fifth of the state, while the eastern part is in dry, rolling plains, needing irrigation to make it productive. The mountainous part rises from 8,000 to 11,000 feet high, with high valleys and passes, but the eastern plains are lower than Colorado or Wyoming, so that the climate is somewhat milder. The dry regions of the east have already been improved by canals and reservoirs, built by private enterprise. The Bad Lands, as they are called, near the Yellowstone river, have a peculiar soft, sticky soil, in which animals sink at every footstep. The Rocky mountains cross the state for 300 miles, with numerous smaller ranges and fertile valleys. The Missouri river has 1,300 miles in Montana, and the Clark's Fork of the Columbia river runs north into Idaho, their sources being scarcely a mile apart. Through a great cañon, cut for five miles through a gorge from 600 to 4,000 feet deep; past Bear Tooth's mountain, 2,500 feet high; by the Long Pool, with its strange, booming noises; over the Great Falls, where, in four separate descents in 15 miles, its waters fall 450 feet, and through five miles of rapids, the Missouri river makes its way 4,000 miles to the gulf of Mexico. The Yellowstone, rising in the National Park, crosses the entire state for 850 miles. There are many mountain lakes and numerous mineral springs. The Warm Springs are near the wigwam-shaped geyser, with its smoke ascending like a council-fire, in Deer Lodge valley. Near Helena, the hot springs have created a resort for invalids and tourists, with one of the largest bath-houses known, and a very fine hotel. The climate is variable, with sudden changes, and a scanty rainfall east of the mountains, while in the northwestern part of the state, the rainfall is more ample, and the climate made milder by the great, warm current from Japan. Stock-raising is one of the industries of the country, the flocks running wild, guarded by shepherds and dogs, and horses and cattle are kept in large herds on the great ranches. The greatest wealth of the state is mineral, and its foremost industry is mining. About one-third of the gold, silver, copper, and lead mined in the United States is from Montana. The first gold was discovered in 1852, but little was done in mining until 1860, the mines now producing enormous quantities, and bringing great wealth to their owners. Silver, lead, and copper are also mined, these, with gold, producing in one year nearly $70,000,000. Large beds of coal and deposits of iron-ore are also found. The College of Montana (Presbyterian) at Deer Lodge, the Montana Wesleyan university, at Helena, and Montana university, at Missoula, are some of the institutions of this new state. There are several United States' posts on the boundary line of Canada and at other places, to keep in check the Indians, and four Indian agencies with their reservations. Montana was admitted to the Union in 1889, and has a popu-

lation of 243,329, of which 12,500 are Indians. Its capital is Helena (population 10,770). The other chief towns of the state are Butte City (population 30,470), and Great Falls City (population 14,930). Montana was early visited by fur traders and French missionaries, but was not settled until after the gold discovery, in 1861. It has been the scene of many Indian wars, notably the terrible massacre of General Custer's forces by the Sioux. See *Washington, Idaho, and Montana*, by H. H. Bancroft.

Mont Blanc (*mŏnt blŏn*). See ALPS.

Montcalm (*mont-kăm'*), **Louis Joseph,** Marquis **de**, was born near Nimes, France, Feb. 29, 1712. He became commander of the French army in Canada in 1756, capturing very soon after the British fort at Oswego. Crossing Lake George, with 8,000 French and Indian troops, he took Fort William Henry, where the massacre by the Indians of the helpless women and children has left a blot on his memory. He defended Ticonderoga against a large British force under Abercrombie, and then moved to protect Quebec. In the attack by General Wolfe, the French were driven back into the city and in the retreat Montcalm was fatally wounded, dying the next morning, Sept. 14, 1759. When told of his danger he said, "So much the better; I shall not live to see the surrender of Quebec." See *Montcalm and Wolfe*, by Parkman.

Montclair', **N. J.**, a picturesque, progressive town in Essex county, five miles northwest of Newark, and fourteen miles from New York, many of whose merchants and business men have their homes here. It is on the Delaware, Lackawanna, and Western, and the New York and Greenwood Lake railroads. Montclair Heights, a charming suburb, has an elevation of 370 feet above tide water. It has a number of fine churches, schools, libraries, banks, and other adjuncts of a growing city. Population 13,962.

Monte Carlo (*mon'tā kar'lō*), a small town in Monaco, known as a great resort of gamblers. The gaming rooms are built on ground owned by the prince of Monaco, and are owned by a stock company. The number of visitors often reaches 400,000. See MONACO.

Montefiore (*mon-te-fē-ō'rā*), Sir **Moses,** a Jewish philanthropist, was born at Leghorn, Italy, Oct. 24, 1784, though London was the home of his parents. He inherited wealth and became a successful stock broker. He became prominent in all efforts to improve the condition of the Jews, making seven journeys to the east, visiting Poland, Russia, Rumania, Damascus, and Jerusalem, to investigate their condition and relieve their oppressions. His last journey was made when he was ninety-two years old. At Bucharest, he faced an anti-Jewish mob, at the risk of his life. He established colonies of Jews, and refuges for the poor in Palestine. His benevolence was not confined to his own race; he gave largely to all charitable institutions, and in 1835 was one of the parties to the contract to pay $75,000,000 to the owners of slaves in the British dominions, to compensate them for freeing their slaves. He was knighted in 1837, and in 1846 made a baron, in recognition of his services to the poor. He died at Ramsgate, in England, July 28, 1885, when 100 years old. See *Diaries of Sir Moses and Lady Montefiore.*

Montenegro (*mon-te-nā'grō*), a small, independent state in southern Europe, in the Balkan peninsula, covering 3,630 square miles, less than half the size of New Jersey. Its extreme length is a little over 100 miles, with a width of 80 miles. It has a low coast region on the Adriatic, and then a mountain region, 6,500 to 8,000 feet high, broken up into peaks and crags, and ravines and gorges, with rivers, running often for miles underground. The mountains are well wooded and give good pasturage. There is very little of the country that can be cultivated; the farms are small, and the fields are little patches clinging to the mountain sides. Corn, rye, oats, barley, potatoes, and fruits are the products. The people live in small stone houses in villages. They are Slavs, and belong mostly to the Greek church, and number about 228,000. They are sturdy mountaineers, whose business for many generations has been to fight the Turks. Montenegro formed part of the Servian empire in the 14th century, but secured its independence when Servia was conquered by the Turks. At one time they were governed by bishops, but in 1851, they separated the state from the church, elected a prince, and made the throne hereditary in his family. The country is progressing rapidly in the last few years. Good roads have been built, fields cultivated, and a standing army maintained. There is a rich literature of patriotic songs and ballads, and their former prince, Peter II. (1830–51), was one of the greatest poets that has written in the Servian language. The first Slavonic books were printed in Montenegro in the 15th century. The capital is Cettinjé (population 2,920). See *Montenegro*, by Denton; *A Winter in Albania*, by H. C. Brown.

Monterey', a city, the capital of the inland state of Nuevo Leon, in northern Mexico. It is a well-built town with tasteful houses, handsome churches, a cathedral, colleges, and government buildings. It is one of the most prosperous manufacturing towns of Mexico. It was founded in 1599. In the Mexican war it was besieged and taken by the American forces under General Taylor, Sept. 24, 1846. Population 45,695.

Montesquieu (*mŏn-tes-kū'*), **Charles de Secondat,** Baron **de**, a French writer of

eminence, was born near Bordeaux, France, Jan. 18, 1689. He was also called Charles Louis de la Brède. He was councilor of the parliament of Bordeaux, and afterward president. His studies were at first in the direction of the natural sciences, but his eyesight failing, he turned his attention to literary work. His first success followed the publication of the *Persian Letters*, pretending to have been written by two Persians who visited Paris, and are satires on French customs and society. He spent three years in travel, observing the institutions and habits of foreign countries. In England he remained two years, seeing its best society, and studying its philosophy in the writings of Locke and others. His ablest work, *Thoughts upon the Causes of the Greatness of the Romans, and of Their Decay*, appeared in 1734. Another great work, the product of twenty years of toil, was *The Spirit of Laws*, published at Geneva, in two volumes, in 1748. While this book came too late to save France from the revolution, it guided its best thinkers in the restoration of order and civil government. His eyesight failed entirely before his death, which took place in Paris, Feb. 10, 1755.

Montevideo (*mon-tē-vid'ē-ō*), the capital of Uruguay, is situated on the north shore of the La Plata inlet, about 125 miles south of Buenos Ayres. It is built on a low point between the ocean and a small bay, and has stretched out to the foot of a hill 505 feet high, crowned by an old fort and a lighthouse. It covers about five square miles, with broad, well-paved streets. A cathedral with towers and a fine dome, opera house, town hall, university (with 91 professors and 694 students), museum, etc., are among the public buildings. It has large beef-salting establishments, where 200,000 cattle are killed yearly; and other industries, mainly of articles for home use. It is the cleanest and healthiest city in South America, and has a large foreign population, brought mainly from Italy, Spain, and France. The first settlement dates back to 1726. Population 266,000.

Montezuma II. (*mon-tē-zū'mȧ*), the last of the Aztec emperors of Mexico, born in 1479 and ascended the throne in 1502. He gave his chief attention to the improvement of the laws of the country, and to building the magnificent palaces that are forever associated with his name. His enormous expenses led to heavy taxation, which resulted in many revolts among his people. When Cortez, the Spanish conqueror, landed in Mexico in 1519, Montezuma tried to buy him off with his treasures of gold and silver. Admitting him to his halls as a guest he soon found himself a prisoner in the Spanish camp. To quiet a revolt of the people Cortez led out Montezuma, who was wounded by a stone thrown by some one in the crowd. This, added to his other indignities, broke his heart, and tearing the bandages from his wound he refused all remedies and food, and died at Tenochtitlan, June 30, 1520. See CORTEZ. See *Conquest of Mexico*, by Prescott; *Story of Mexico*, by Hale.

Montfort (*mont'fort*), **Simon de,** earl of Leicester, an English general and statesman, the leader in the war of the barons against the king (Henry III.), was born in the beginning of the 13th century. His English title came to him through his grandmother and was confirmed to him by Henry III. in 1232. He married the king's sister, who had devoted herself to the church, but Montfort succeeded in obtaining the sanction of the pope. The king drove him, however, from his court, and he probably went on a crusade to the Holy Land. The king was surrounded with foreigners, who fared sumptuously at the expense of the people; bad harvests and famine added to their discontent, until in 1258 the barons appeared in arms before parliament and demanded the driving out of the foreigners and the appointment of a committee of twenty-four to manage affairs. Later in the same year, parliament, sitting at Oxford, drew up a set of laws, called the provisions of Oxford, which the king agreed to. By these provisions the foreigners were to surrender their castles, and Montfort gave up Kenilworth and Odiham. In 1261, the king repealed this act, which brought Montfort to the front as leader of the barons in their contest with the king. He surprised the king's army at Lewes and captured the young prince May 14, 1264. In his arrangements for a peaceable settlement of the difficulties a parliament was called, in which the barons, bishops, and abbots sat, with four knights chosen from each shire, and for the first time in England two representatives from certain towns. This may be looked upon as the germ of the modern parliament. He was, however, ahead of his times; the barons were dissatisfied and Gloucester deserted; the young prince escaped, and joining with Gloucester defeated Montfort, Aug. 4, 1265. He was killed on the field of battle (Evesham), but his memory survives among the people who know him as St. Simon. *The Song of Lewes*, first printed in a collection of political songs in 1839, is a full account of this constitutional struggle of the barons. See *Constitutional History of England*, by Stubbs; and *Life*, by Prothero.

Montgomery (*mŏnt-gŭm'er-ĭ*), the capital of Montgomery county, Ala., is situate on the Alabama river. It is surrounded with fine country seats and is a growing city, with artesian water, electric lights, and other modern improvements. Since 1865 the manufactories have increased rapidly, including foundries, steam mills, cotton gins, and oil works. The state capitol is a fine building, overlooking a wide stretch of country. The city is 400 miles from Mobile, on the Alabama river, a distance that formerly was

passed over by flatboats in a three months' journey. Population 30,346.

Montgomery, Richard, an American general in the Revolutionary war, was born in Ireland, Dec. 2, 1736. While an officer in the British army he took part in the siege at Louisburg, and in the attacks on Martinique and Havana. In 1775, he was made a brigadier-general in the American army and put in command of the army sent into Canada. He took possession of Montreal and St. Johns (Fort Chambly), and a large part of Canada, and rose to the rank of major-general. He drew up his forces in union with Arnold's troops before Quebec, Dec. 4, and when it was decided to carry the city by assault, Montgomery commanded the attack on the upper city. He fell dead at the first and only onslaught by the British, while pressing on the second barrier, Dec. 31, 1775. Congress erected a monument to his memory at St. Paul's church in New York.

Montmorency (*mont-mô-rĕn'sĭ* or *mon-mô-ron-sē'*), **Anne de,** first Duke of, marshal and constable of France, was born at Chantilly, March 15, 1492. He won distinction at the battle of Marignano, and was captured with Francis I. at the battle of Pavia in 1525. The king made him constable of France in 1538, but suspecting him of favoring the dauphin, he banished him from court in 1541. Under Henry II. he was restored to his honors and position, and commanded the French army in the defeat at St. Quentin, where he was again taken prisoner by the Spaniards. He was one of the three statesmen who opposed the influence of the regent, Catherine de Medici. He was captured a third time in 1562, in an attack against the Huguenots, and the next year drove the English out of Havre. He received a fatal wound in the battle against Condé at St. Denis, and died at Paris the next day, Nov. 12, 1567.

Montmorency, Falls of, are in the Montmorency river, eight miles below Quebec, where it empties into the St. Lawrence. The water falls over a precipice 250 feet high, and 50 feet wide. There is a series of natural steps above the falls worn by the water, and at the foot of the falls an ice mountain, sometimes 200 feet high, is formed every winter. It is a place of resort for tourists.

Montpelier (*mont-pĕl'yer*), is the capital of Vermont, and the chief city in Washington county. It is on the Onion river, 206 miles from Boston. It is built on a plain, surrounded by hills. It has a granite state house, with a statue of Ethan Allen, a Vermont seminary, a Methodist institution, and several mills, machine shops, and tanneries. Population 6,266.

Montpellier (*mon-pĕl'lyā*), a French city, 76 miles northwest of Marseilles, and six miles from the Mediterranean. The chief modern buildings are the theatre and law courts, and there are two great terraces used as promenades, with fine views of the Mediterranean, the Cevennes, Pyrenees, and Alps. Its great industry, the production of wine, at periods suffers by the phylloxera, a minute insect that attacks the vines and almost destroys the vineyards; the cure effected by grafting the vines upon American stocks was first tried here. There is a flourishing school of agriculture devoted to the study of wine and silk culture. Montpellier is more celebrated, however, as an ancient city, belonging to Aragon, or Navarre, before it finally became a French city in 1392. Its university (1289), with schools of law, medicine, and arts, rivaled that of Paris. Petrarch, Rabelais, and Casaubon, were pupils or teachers in its halls. A famous botanic garden, the oldest in France, was started in 1593, where De Jussieu and De Candolle, the well-known French botanists, studied and wrote. The university has passed its six hundredth anniversary and is well equipped. Population 73,931.

Montreal (*mont-rē-awl'*), the largest and chief commercial city of Canada, is built on

an island formed by the union of the Ottawa and the St. Lawrence rivers. The city is four miles long and nearly three in width. Its churches and schools are numerous, and some of them have very fine buildings. The Church of St. Peter's is like that at Rome, on a smaller scale; that of Notre Dame holds 10,000 people, and Christ church, Episcopal, has a tower 224 feet high. The large majority of schools are Catholic; the taxes paid by Catholics go to the Catholic schools, and those paid by Protestants to the Protestant schools. McGill university, the seminary of St. Sulpice, Presbyterian, Congregational, and Methodist colleges provide for higher education. There are musical, art, and historical associations. The city has an enormous commerce. Its canals enable it to trade with Duluth and Fort William on Lake Superior, Chicago

and Milwaukee on Lake Michigan, Buffalo and Cleveland on Lake Erie, and Oswego on Lake Ontario, while 1,500 miles of the St. Lawrence adds to its water routes on the way to the sea. It has large establishments engaged in boot and shoe making, clothing and tobacco manufactures, besides breweries, cotton mills, and sawmills. Montreal was founded by the French in May, 1642. Its early history was one of constant Indian wars, it being almost destroyed by them in 1660. In 1760, the French surrendered it to the British. During the Revolutionary war, it was occupied by American troops, who were driven out in 1777. Since that time the history of Montreal has been one of peace and prosperity. Population in 1901, 266,826.

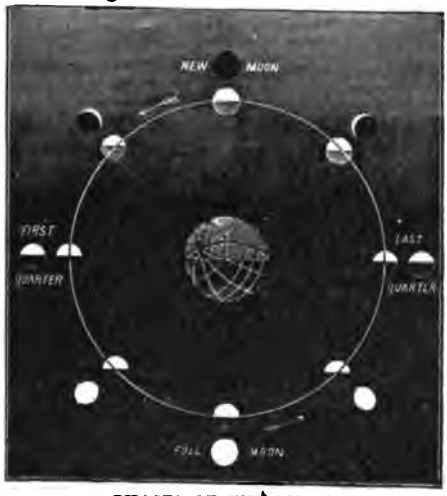
Mood'y Dwight Lyman, was born at Northfield, Mass., Feb. 5, 1837. In early boyhood he was thrown, with several other young children, upon the care of his widowed mother. At the age of seventeen he began a business career in Boston, where he attended Sunday school and soon became an earnest Christian convert. A young man of great enthusiasm and energy, he at once zealously embraced Christian work. Wishing to strike out a new path for himself, he went to Chicago. Here a tireless worker both in the store and the church, he settled down to the work of a "Sunday school scout," perhaps the roughest of all Christian service—the hunting up of ragged children in the worst parts of the city and winning them to school, and to a good life. Soon a deserted saloon was hired for a Sunday school, which Moody built into a great mission.

DWIGHT L. MOODY.

The breaking out of the war, in 1861, gave the evangelist a chance of doing great good, which was improved to the utmost. Backed by 150 ministers and laymen, he carried on a great revival among the soldiers at the recruiting camp near Chicago. Soon a call came from the field in the interest of the sick and wounded. Back and forth between Chicago and the various camps and battlefields Moody toiled and traveled; he was on the field after the battles of Shiloh and Murfreesboro, and was one of the first to enter Richmond.

Moody's great work was as an evangelist, but his many converts in Chicago, who had founded a church, forced him to become their pastor. But this charge could not keep him from carrying on those great revivals in all parts of the country which were so successful and which will always hold his name in remembrance. In 1870, and in 1883, with Ira David Sankey, he visited England, where his success was as great as it had been in America. Another great agency for good which we owe to Moody is the summer school for Bible study held at Northfield, where young Christian workers study the Bible, under the teaching of the foremost preachers and professors of America and Europe. Connected with this school is the institute for the training of young men for this same work, which was founded from the proceeds of the sale of Moody and Sankey's *Gospel Hymns*, the most popular hymn book ever published. Many of Mr. Moody's fine and practical sermons have been published. See *D. L. Moody and His Work*, by Daniels. He died Dec. 22, 1899.

Moon, a satellite of the earth and our nearest neighbor in the stellar universe. The



PHASES OF THE MOON.

distance of the moon from the earth varies from 221,614 to 252,972 miles. Its apparent mean diameter is 31′ 7″ so that its real diameter is 2,163 miles, and its volume only $\frac{1}{49}$ that of the earth. The mass of the moon, however, is only about $\frac{1}{80}$ that of the earth, which makes the acceleration of gravity at the surface of the moon only $\frac{1}{6}$ that of the surface of the earth. Professor Young illustrates this by saying that "a man on the moon could jump six times as high as he could on the earth and could throw a stone six times as far." The absence of any atmosphere or water on the surface of the moon has been proved by its appearance in the telescope, by the spectroscope, and by the absence of refraction in the occultation of stars.

The moon, like the sun, moves constantly toward the east among the stars; but it gains 12° 11.4′ daily on the sun. Accordingly the moon requires $\frac{360°}{12° 11.4'}$ days to gain one complete revolution on the sun. This length of

time, which is $29^d\ 12^h\ 44^m\ 2.7^s$ is called one *month*. This is also exactly the time required for one rotation of the moon upon her own axis. The consequence is that she always keeps the same side toward the earth. The other side of the moon is something that no inhabitant of the earth has ever seen. The reason why the period of the moon's rotation is exactly one month is a matter which is thoroughly understood — namely, tidal friction — but is too advanced for discussion in this place.

The various phases which the moon presents will be clear from the accompanying figure which represents the earth and the moon's orbit, illuminated by a sun at a great distance above the top of the page. When the moon lies exactly in the direction of the sun we say it is "new." In this position we see none of its illuminated hemisphere; but as the moon moves away from the sun's direction we see more and more of the illuminated portion. At the end of one week, half of the bright surface is seen by an observer on the earth, and we speak of this as a "half moon." A week later we see the complete illuminated hemispere and call it "full moon." The moon now begins to wane and passes through these same phases, in reverse order, until the next "new moon."

The moon has been in all ages — and is yet — the subject of many superstitions. Witness such words as *moon-struck* and *lunacy*.

Moon'stone. See FELDSPAR.

Moore, Sir John, an English general, was born at Glasgow, Scotland, Nov. 13, 1761, and died at Corunna, Spain, Jan. 16, 1809. He entered the army when only fifteen, and served at Corsica, in the West Indies, in Ireland, and in Holland. He obtained the order of the Bath for his services in Egypt in 1801. In 1802, he was with the army in Sicily and in Sweden, and in 1808 he was sent with an army of 10,000 men to strengthen the English army in the peninsula, and was put in command of the whole force soon after his arrival. The Spaniards failed to support him, and when, after the fall of Madrid, the news reached him that Napoleon with 70,000 men was marching against him, he began a retreat with his army of 25,000 men. They marched for nearly 250 miles through a mountainous country, almost impassable from snow and rain, and while embarking on their ships at Corunna were attacked by the French troops under Soult. The French were defeated with the loss of 2,000 men, but the brave leader was struck by a cannon-ball and died in the moment of victory, and was buried at night just before the troops embarked for England. The story is preserved in the well-known lines of the Rev. Charles Wolfe on the burial of Sir John Moore. See *Life*, by Moore; *Peninsular War*, by Napier.

Moore, Thomas, an Irish poet, was born at Dublin, Ireland, May 28, 1779. He was educated at Trinity college, Dublin, and in 1799 went to London, bringing out, in 1800, a translation of *Anacreon*, which, with his musical talent, opened to him the best society. His *Poetical Works of Thomas Little* (a pseudonym of Moore's) followed. In 1803, he was given an official position at Bermuda, which he visited, and appointed a deputy to his office, traveling afterward in the United States and Canada. He published, after his return, the earlier part of the *Irish Melodies*, and in 1817, *Lalla Rookh* appeared, and the whole English world applauded. He received $15,000 for the latter, and the *Irish Melodies* brought him $2,000 a year; but his deputy in Bermuda embezzled $30,000, of which sum he was obliged to pay $5,000, and in 1819 he departed for Italy to avoid arrest for the debt. He returned to England in 1822, spending the last thirty years of his life at Sloperton cottage in Wiltshire. His later works were a *History of Ireland* and lives of Sheridan, Byron, and Fitzgerald. He received a pension of $1,500 in 1835. His death occurred Feb. 25, 1852. See *Memoirs, Journal, and Correspondence*, by Earl Russell.

THOMAS MOORE.

Moors, a name given to the people living in Barbary, in northern Africa. Among them flourished the Christian church of Africa for three centuries, with Tertullian and Augustine as its leaders. The country was overrun by the Vandals from Spain in 429, and reconquered by the Byzantine emperors in 533. In 647, the Arabs subdued it, and the Moors became Mohammedans, and have so remained ever since. With the exception of Tripoli and Morocco, these countries now belong to France. The Moors have always been a mixed race. In history the name is given especially to the Arab conquerors of Spain from 711 to 1492. For a short time one caliph ruled from Bagdad to the Atlantic ocean. The Moors were finally driven from Spain in the reign of Ferdinand and Isabella (1492). They were far ahead of the people of northern Europe in architecture, literature, science, and agriculture; but after the 12th century they fell behind the Christian nations, who were developing rapidly, and their own divisions hastened their overthrow. See *Moors in Spain*, by Stanley Lane-Poole.

Moose. See ELK.

Moose'head Lake is situated in the state of Maine, the source of the Kennebec river. It is the largest lake in Maine, 35 miles long and from 3 to 12 miles wide. Spencer mountain, 4,000 feet in height, is on the eastern shore. There is fine game in the region, especially deer and caribou, which, with the attractive scenery, makes it a popular resort.

Moran (*mo-ran'*), **Thomas,** an American artist, was born at Bolton, in Lancashire, England, Jan. 12, 1837. His early life was spent at Philadelphia, where he learned engraving, studying painting afterward in England, France, and Italy. His large paintings, the *Grand Cañon of the Yellowstone* (7 by 12 feet in size), and the *Chasm of the Colorado*, were bought by congress for $20,000. These were the first landscapes ever purchased by the government. His other works are mostly of the same class: *Balboa discovering the Pacific*, *Hiawatha and the Serpents*, and *The Wilds of Lake Superior*, being examples of his paintings.

Mora'vians, a band of Protestants, formed from among the followers of John Huss, who claim to be the modern representatives of the ancient Bohemian church. They are called also "the church of the United Brethren." Their church was formed after the model of the apostles and early Christians; all distinctions of rank were done away with; they were opposed to taking the oath, or giving military service. The first formation of the church was in 1467, in Bohemia, increasing to between 300 and 400 churches in the beginning of the 16th century, when, from persecutions, many fled into Poland and Prussia. In 1600, they numbered among their followers two-thirds of the Bohemian nation, but were involved in the revolution of that period, and the church was almost destroyed. A few descendants of the old Moravians founded, in 1722, a colony at Herrnhut, in Saxony, on land given by Count Zinzendorf, and in 1727, formed anew their church. Their community was a pattern for other settlements in Germany, America, and Britain, often named for the mother colony, Herrnhut. Count Zinzendorf was one of their first bishops, and had much influence in deciding their customs of worship. They number now about 70,000 followers. The great distinction of the Moravians is their missionary zeal. Their first missions were started as early as 1732 in the West Indies, followed by mission work in Greenland, Lapland, North and South America, and Africa. Their missions among the American Indians were successful, one of their well-known stations being at Gnadenhutten, in Ohio, among the Tuscarawas. One out of every fifty members of the Moravian church is engaged in mission work, and there are three times as many members in their mission churches as in the home churches. The most abandoned, hopeless, and miserable people have been the first choice of the Moravian missionaries, as their missions to slaves, lepers, Indians, and gypsies testify. The Moravian church in the United States has about 15,000 communicants, 118 ministers, and 110 churches. Their great strength is in Pennsylvania. See *Missions*, by Thompson; Hutton's *Short History of the Moravian Church;* and *History*, by Bost (English translation).

Mor'ay, or **Mur'ray, James Stuart,** Earl of, Scottish regent, illegitimate son of James V. of Scotland, was born about 1533. In 1556, he joined John Knox and the reformers, and became the head of the Protestant party in Scotland. When Mary Queen of Scots returned to her kingdom, he acted as her prime minister. He opposed her marriage to Darnley, in 1565, and contested it with an army, but was defeated, and fled to England, not returning to Scotland until after Rizzio's murder, in which he seems to have been involved. He was recalled from France in 1567, to find Mary in prison and himself regent of the kingdom. After his escape, he defeated her forces at Langside, near Glasgow, May 13, 1568, and was one of the commissioners sent to England to make arrangements for her safe custody, and testified against her when tried for the murder of Darnley. He managed Scotland well, but was shot from a window, Jan. 21, 1570, by Hamilton, of Bothwellhaugh, either from personal enmity, or at the suggestion of Mary's friends. See *History of Scotland*, by Robertson.

More (*môr*), **Hannah,** was born near Bristol, England, in 1745. She wrote verses when very young, publishing a drama, *The Search for Happiness*, when only seventeen years of age. This was followed by two tragedies, *Percy*, and the *Fatal Secret*, both of which were acted. She visited in London, going much into society, and making friends of Johnson, Sir Joshua Reynolds, the Garricks, and others, but became dissatisfied with her life, and retired to a cottage near Bristol. She continued her literary work, but gave much of her time to helping the poor, and originating schools for them. Her novel, *Cœlebs in Search of a Wife*, and the tract, *The Shepherd of Salisbury Plain*, are the most popular of her works. The tract has had an enormous circulation. She made by her writings $150,000, leaving one-third of this sum to charitable objects. She died, at Clifton, Sept. 7, 1833. See *Life*, by Roberts, and one by Yonge.

More, Sir Thomas, English statesman and author, was born at London in 1478. He acted as page, according to the fashion of the times, in the house of Archbishop Morton, who said to his guests, "This child waiting at the table will prove a marvelous man." At Oxford, he met Livacre and Colet, who

had traveled in Italy, and brought with them the new ideas and learning of the time. More, already a fine Latin scholar, studied Greek with Livacre, and from Colet received a spiritual impulse, which made him ready for his famous friendship with Erasmus, whom he met about 1498. When Henry VIII. came to the throne, More was already known as one of the leading scholars of the time, had been in parliament, and acted as ambassador to the Netherlands, so that Henry naturally gave him public office. Although disinclined toward public life, he rose rapidly, becoming treasurer of the exchequer, speaker of the house of commons, and, on the fall of Wolsey, in 1529, lord chancellor. The king became intimate with him, making unexpected visits at his home at Chelsea, but when congratulated on the king's friendship, More replied, "If my head would win him a castle in France, it should not fail to go." He was sent on embassies to Francis I., and Charles V. As chancellor "he was ready to hear every man's cause, poor and rich," and the only fault found has been with his decisions in religious matters. Like Erasmus and Colet, while welcoming reforms, he did not desire to leave the old church. He parted with Henry on the question of the divorce of Catherine of Aragon, and refused to take the oath acknowledging Henry as head of the church. He was beheaded on Tower Hill, London, July 6, 1535. The story of his daughter Margaret's midnight ride, with only a half-foolish jester for companion, to London bridge, where her father's head was exposed; holding out her apron, as she sat in the boat, while the head was dropped into her lap, to be carried off for burial, is one of the most touching in English history. Sir Thomas More ranks high among the writers of England. His works were generally written in Latin; his *History of King Richard III.*, however, in 1513, was written in English, and is perhaps the first example of classical English prose. His great work, *Utopia*, in Latin, made him the one literary Englishman of the 16th century who was known and admired on the continent. It was translated by Bishop Burnett in 1556, and still holds its place as an English classic. See *Life*, by Roper; *Lives of the Chancellors*, by Campbell; and *Household of Sir Thomas More.*

Moreau (*mo-rō'*), **Jean Victor,** one of the greatest of French generals, was born Aug. 11, 1761, in Brittany. In the revolution, he served first under Dumouriez, and was soon made commander of a division, taking an active part in reducing Belgium and Holland. In the spring of 1796, he was given the chief command on the Rhine and Moselle, driving the Austrians back to the Danube, and regaining the Rhine in a retreat that gave him more reputation than all his victories. In 1798, he saved the French army in Italy from destruction, when hard pressed by the Russians and Austrians. His command was given to Joubert, but at his request, Moreau remained with the army, and after Joubert's death, he brought the defeated troops to France. He was offered the dictatorship, but declined, giving his help to Bonaparte. Again in command of the army of the Rhine, he gained victory after victory over the Austrians in 1800, ending with the great battle of Hohenlinden. Napoleon, possibly moved by jealousy, accused him of taking part in a plot against his life, and had him tried. The evidence against him was insufficient, but he was exiled, and came to America in 1804. In 1813, while with the emperor of Russia, and the king of Prussia, in their march on Dresden, he was struck by a cannon-ball, and died at Laun, in Bohemia, Sept. 2, 1813. See *Memoirs* by Philippart.

Mor'gan, Edwin Dennison, an American statesman, was born at Washington, Mass., Feb. 8, 1811. Beginning life as a boy merchant in Hartford, Conn., he, some years later, transferred his business to New York city, from which place he was elected to the state senate in 1850, and he became, at the organization of the Republican party, one of its active and trusted leaders. In 1858, he was elected governor of the state, and he served in that capacity through the critical first years of the Civil war, becoming United States senator in 1863. During his term of office he assisted in the raising and sending to the front of 220,000 volunteers. He was offered the position of secretary of state by President Lincoln, in 1865, and that of secretary of the treasury by President Arthur in 1881; but he declined both. By will he left $795,000 to charities, having during his lifetime also given away vast sums. He died at New York, Feb. 14, 1883.

Mor'gan, John Hunt, a Confederate general, was born at Huntsville, Ala., in 1826. In the Civil war he took the Confederate side; was a bold and successful raider, and his troops were the terror of the border regions, and known as "Morgan's Guerrillas." He is celebrated for what is known as Morgan's raid, in which, crossing the Ohio, he dashed through southern Indiana and Ohio, but was captured while recrossing the river, and confined in the Ohio penitentiary. After his escape, he led another raid into Tennessee, but was surprised and killed at Greenville, Tenn., Sept. 4, 1864.

Mor'gan, John Pierpont, an American financier,— son of Julius S. and his wife, the daughter of John Pierpont,—was born at Hartford, Conn., April 17, 1837. He was educated at the high school in Boston and the University of Göttingen, Germany. He began his career as a banker in 1857, in New York city; and in 1860, was appointed the American agent of the London firm of George Peabody and Company. In 1864, he became one of the firm of Dabney, Morgan and Com-

pany; and in 1871, he became a partner of the Drexels. He took a lively interest in railroad management, being director in a number of roads and active in the reorganization and successful development of lines that had failed in other hands. In 1895, he successfully conducted a syndicate formed for the purpose of purchasing United States four per cent. bonds. Mr. Morgan became director in no less than 23 railroad companies by 1900, and it was through his efforts that the great steel manufacturing interests of the countries were combined into a company having a capital of $1,100,000,000. In 1901, he purchased three lines of ocean steamers, and he is at present engaged in the largest financial transactions which have ever been entered into by private individuals.

JOHN PIERPONT MORGAN.

Mor'gan, John Tyler, an American soldier and statesman, was born at Athens, Tenn., June 20, 1824; emigrated to Alabama in 1833; was admitted to the bar in 1845; became a delegate to the Alabama Secession Convention in 1861; joined the Confederate army in 1861, and, passing through all grades from private upward, was made brigadier-general in 1863, and served to the close of the struggle. In 1877, he was elected to the United States senate. In 1892, he was appointed arbitrator on the Bering sea fisheries by President Harrison. In 1898, he was appointed by the late President McKinley one of the commissioners to organize a territorial government in Hawaii.

Morgarten (*môr-gär'ten*), a mountain on the border of Lake Egeri, in Switzerland, near by which is the scene where 1,400 Swiss from the cantons of Schwyz, Uri, and Unterwalden won a great victory over 15,000 Austrians, Nov. 15, 1315.

Morghen (*mor'gen*), **Raphael Sanzio Cavaliere,** a famous Italian engraver, was born at Naples, June 19, 1758. He studied at Rome, and his first works were very successful. Almost all of the great masterpieces of art of the time were engraved by him, Raphael's *Transfiguration* and Da Vinci's *Last Supper* being among them. He made his home at Florence, in response to an invitation of the duke, who gave him a pension and a house, on condition of his establishing a school of engraving. His *Transfiguration*, upon which he spent sixteen years of labor, was dedicated to Napoleon, who paid him much attention. His life and a catalogue of 254 of his engravings were published by a pupil. He died at Florence, April 8, 1833.

Mori'ah, Mount, a hill in Palestine, forming a part of the site of the city of Jerusalem. Solomon's temple was built upon it, and at its foot, in the valley of Jehoshaphat, is the Virgin's Fountain, an intermittent spring from which the water flows through an aqueduct cut into the mountain into the Pool of Siloam. When the temple was destroyed, at the taking of Jerusalem, Mount Moriah was literally plowed over. It is now the site of the great mosque of Jerusalem, which occupies about one-seventh of the present city.

Mor'ley, Henry, an English author and educator, was born at London, Sept. 15, 1822. He was a student at King's college and afterward in Germany. He practiced medicine from 1844 to 1848. For two years he was an instructor, and for some years later a journalist. He was lecturer upon English literature in King's college, London, from 1857 to 1865; and from 1865 to 1889 was professor of English language and literature in University college, London. He resigned the latter position in 1889. He published *Palissy the Potter* as early as 1852, and up to his death, in 1894, was continuously engaged upon some literary work. In 1864, he began a series of works to illustrate all schools of English literature. He also edited for Cassell's National Library over 200 volumes, and for Routledge and Son a series of 63 volumes known as *Morley's Universal Library*. Another series of 14 volumes, *The Carisbrooke Library*, he issued later. Few writers have been more industrious, prolific, or reliable as to fact and judgment than he. He died at Carisbrooke, England, May 14, 1894.

Mor'ley, John, an English statesman and writer, was born at Blackburn, Lancashire, Dec. 24, 1838, and was educated at Oxford. He chose literature as a profession, writing *Edmund Burke*, *Walpole*, *Rousseau*, *Voltaire*, *Richard Cobden*, an essay on *Compromise*, and *Critical Miscellanies* among others, and editing from 1867 to 1882 the *Fortnightly Review*. He was also the editor of the "English Men of Letters" series. From 1880 to 1883, he was editor of the *Pall Mall Gazette*. In 1880, he entered parliament as a Liberal, where his speeches in favor of home rule, as well as his newspaper articles, did much to influence public opinion. In 1886, he was Irish secretary for a short time. He supported Gladstone in 1890, and from 1892 to

RT. HON. JOHN MORLEY.

1895, was secretary for Ireland. He is popular as a public speaker; and opposed the Salisbury government in undertaking the Boer war in South Africa.

Mormons, called also "latter-day saints," constitute a peculiar religious community. Their belief is founded upon revelations said to have been made to a young man, named Joseph Smith, living at the time in Manchester, N. Y. Born in 1805, in Vermont, he was fifteen years of age when in 1820 he had his first vision; his call, as he considered it, to the work of a prophet. This was followed in 1823 by a revelation of the place where he would find the sacred book of the Mormons. In 1827, the books were put into his hands with two silver plates, called the Urim and Thummim, looking like a pair of spectacles, by means of which he read the unknown language of the books, dictating it to his friend, who wrote it down. Eight persons were permitted to see the original book and the silver plates, which then were returned to the angel Gabriel, who had brought them. Such is the story of the origin of the Book of Mormon, the first edition of which was published in 1830, at Palmyra, N. Y. The name comes from Mormon, the prophet who was commissioned to write the history of his people, a race said to have come from Jerusalem to America, about 600 B. C.; which records constitute the book. It is considered by the Mormons to be of equal authority with the Bible, and the latest revelation from God. The Mormon church was organized in Fayette, N. Y., April 6, 1830, with six members. Converts soon were numerous, and branches were founded in New England, Ohio, and Pennsylvania. In 1831, they formed a colony in Missouri, at a place revealed to them as the site for their capital city. Here, and in Ohio, they were persecuted, their printing presses destroyed, their bishops tarred and feathered, and finally the Missouri colony was driven out entirely. A company went to England in 1837, and made 2,000 converts in a short time. They prospered in their new home in Missouri, their city named Far West, to which most of the Ohio Mormons had gone; but a popular rising against them, in August, 1838, led to their being driven from the state by order of the governor. They founded in Illinois the city of Nauvoo in 1838, about twelve or fifteen thousand of them coming into the state, where they were kindly received. But in a few years the popular dislike broke out afresh, the prophet and his brother, when in prison with others at the command of the governor of the state, were shot by assassins.

Brigham Young, one of the twelve heads of the church, or "apostles" as they call them, came to the leadership, and with a thousand families left Nauvoo in February, 1846. They wintered in Nebraska, and in the spring of 1847 Young, with a band of 143 men, set out for the Rocky mountains, reaching the Great Salt lake, the site of their new city, in July. Others followed in the autumn and the next year. They have now settlements in Idaho, Colorado, New Mexico, and Arizona, besides Utah, in the United States, and also in Mexico and British America. Utah has been a territory of the United States since 1850, and for several years Brigham Young was governor. The Mormons number about 300,000, 110,000 of them being in Utah. They are said to have 796 churches and 1,700 ministers. A new and reformed sect of Mormons have their chief seat at Lamoni, Iowa. The opposition to them in the different states where they settled, and the refusal of the United States government of their request that Utah be then made a state, was due to two of their doctrines or practices: viz, the oath binding them to obedience to their spiritual head in everything, which prevents their obedience to the laws of the country if there is at any time any conflict, and their belief in and practice of polygamy, *i. e.*, having several wives. They were also credited with secretly murdering any one who opposed their practices or revealed their acts, and though the popular impression in this respect was exaggerated, the "Mountain Meadow" massacre of a band of "Gentile" emigrants in 1857, shows that it was not entirely without foundation. President Woodford, as the head of the church in September, 1890, in a proclamation, declared that polygamy is no longer the doctrine of the Morman church. See *History of Utah*, by H. H. Bancroft, and *Early Days of Mormonism*, by Kennedy.

Morocco (*mō-rok'ō*), a country in the northwest of Africa, a Mohammedan empire, consisting of the kingdoms of Fez, Morocco, and the territories of Sus, Adrar, Draa, and Tafilet, under a reigning sultan, whose government is practically a despotism. It contains about 219,000 square miles, of which the Desert of Sahara occupies over 200,000. The Atlas mountains cross it in several ranges from southwest to northeast, making a large part of the country hilly. There are rich, level plains in parts of the country, and though the soil is sometimes thin in the western part, most of it is of use for pasturage, and there is little real desert. The rivers of Morocco, in the wet season rolling full from bank to bank, are in the hot season not much more than pools connected by threads of water, and are none of them navigable for any distance. Parts of Morocco, where the sea breezes prevail, and the Atlas mountains protect from the hot winds of the desert, are temperate; but the interior valleys are very hot in summer, and in winter ice and snow are not uncommon. The products are those of temperate and tropical countries. Wheat, barley, corn, oranges, figs, lemons, and dates are among the exports, while cotton is grown for home use. The cultivation of tobacco and its use are forbidden by the sultan, and no

animal can be sent out of the country without his majesty's permission. The animals resemble those of southern Europe, save a few species which come from the regions of Africa to the south. The mineral wealth is almost unknown, as the interior of the country has not been explored, but gold, silver, copper, tin, iron, coal, and petroleum are evidently abundant. The mines are scarcely touched, and no European is allowed to visit them. The people, numbering anywhere from 2,500,000 to 9,000,000, are divided into six groups; the Berbers, who inhabit the mountain regions, are the original inhabitants; the Arabs, descendants of those who invaded the country in the 7th century; the Jews, who settled early in the region, with many refugees from Spain and Portugal; a few Europeans, mainly Spaniards, confined to the coast towns; the Moors, a name given to all the Mohammedans, but really belonging only to Arabs with a mixture of Spanish blood, found mostly in the large cities; and the negroes, who were brought from the Sudan as slaves. There are three capitals — Fez (population 140,000), Morocco, and Mequinez; the seaports are on the Atlantic, Mogador, and Tangier, and on the Mediterranean, Tetuan, etc.

Morocco was for four centuries a part of the Roman empire, and fell into the hands of the Vandals in 429 A. D., until, in 533 A. D., it passed to the Eastern empire. Since 680 it has been most of the time in possession of the Arabs, and the people have been Mohammedans. It was first a part of the "caliphate" of Bagdad, then divided into several independent monarchies, which, after civil wars and revolutions, became united in one kingdom under Mulai-Ismail, who reigned from 1692–1727. The country is still very backward, and though the enslaving of Christians and piracy were done away with in 1817, the interior is almost inaccessible, and slavery still exists. See *Tour in Morocco*, by Hooper and Ball; *Land of an African Sultan*, by Harris.

Moroc'co, the southern capital of the sultanate of Morocco, is situate at the northern end of a fertile plain, 1,447 feet above the sea. It is surrounded by an earth wall, from 20 to 30 feet high, with square towers at intervals, and seven gates, said to have been brought from Spain. It has the remains of former greatness, but is poorly built, with low, flat-roofed houses without windows, and narrow, unpaved, and dirty streets. It carries on a considerable local trade, though much less than Fez, with several tanning and leather-dyeing establishments. The palace is outside the city, its grounds covering 180 acres; no Europeans live within the city walls. The city was founded in 1072, and in its greatest prosperity, in the 13th century, it contained more than 700,000 inhabitants. It has been sacked more than once in the civil wars, and has steadily declined. Its situation in sight of the Atlas mountains, and its command of the trade routes, make it probable that it will regain its former greatness whenever the country is well governed. Population 50,000.

Morpheus (*môr'fûs* or *môr'fē-us*), in mythology, the son of sleep and the god of dreams. The word means "molder," and he is so called because he molds or shapes the visions of the sleeper. He is represented as an old man with wings, pouring a sleep-producing vapor out of a horn, and sometimes as lying down with a crown of poppies on his head.

Morphology (*môr-fŏl'ō-jy*), in botany one of the great divisions of the subject, which treats of the forms of plants. The older idea of morphology was that it had to do merely with the adult organs, and that it considered merely the various forms of leaves, stems, roots, etc. As at present developed, morphology treats also of the development of organs. For example, it is not content with describing the mature leaf or the mature archegonium, but it states in detail the development of these organs from their most primitive conditions. It includes, therefore, what may be called "organography," that is, the development of organs, and also "embryology," that is, the development of the plant as a whole. Morphology is also closely identified with the relation of plants to one another by descent, and is therefore bound up with what is called "phylogeny," which means a consideration of the ancestral forms of plant races. From this point of view morphology is also the most fundamental contributor to "taxonomy" or classification, which can only be natural when it expresses the real morphology of plants. In any botanical study morphology is regarded as most fundamental, for it underlies all other work with plants.

JOHN M. COULTER.

Mor'rill, Justin Smith, an American statesman, was born in Orange county, Vt., April 14, 1810. He had only a common school education as a boy, and at an early age he engaged in business, which later he gave up for farming. He was elected to congress in 1855, remaining in the house of representatives from 1855 to 1867, at which time he was elected to the United States senate, and later was re-elected for six successive terms of six years each. His congressional service exceeded in length that of any living colleague. He held for many years in the house the important position of chairman of the committee of ways and means, and he was the author of the tariff bill of 1861 known by his name. He wrote *Self-Consciousness of Noted Persons*, published in 1886. He died Dec. 28, 1898, at the capital of the nation.

Mor'ris, Gouverneur, an American statesman, was born at Morrisania, N. Y., Jan. 31, 1752. He was active in political matters during the Revolution. From 1781–84, he was assistant to Robert Morris, who was superintendent of the national finances. In 1787, he

was a member of the convention that framed the United States constitution. He spent part of the year 1791 in England as confidential agent of Washington, and was minister to France till 1794. He was three years (1800–3) United States senator from New York. He died Nov. 6, 1816. See *Gouverneur Morris*, by Roosevelt, in "American Statesmen" series; *Diary and Letters*, by Anne Cary Morris.

Mor'ris, Sir Lewis, an English poet of Welsh origin, who was knighted in 1895 for his verse, was born in 1832, at Carmarthen, Wales, studied at Oxford, and practiced law until 1881, when he was appointed secretary of the University of Wales. His first poems, *Songs of Two Worlds*, published under the name "A New Writer," were very popular, passing through several editions. His *Epic of Hades*, appeared in 1876, and since then, *Gwen, a Drama*, *The Ode of Life*, *Songs Unsung*, *A Vision of Saints*, *Songs without Notes*, and *Idylls and Lyrics*, all of which have been popular.

Mor'ris, Robert, one of the signers of the Declaration of Independence, was born in Lancashire, England, Jan. 20, 1734. He came to America when he was thirteen years old, and entered a counting house at Philadelphia, becoming finally a partner. He opposed the Stamp Act and was elected to the congress of 1775. He voted at first against the Declaration of Independence, but signed it when it was adopted. He was again in congress in 1777 and managed largely the finances of the country. In 1781, he was elected superintendent of finance, and had almost entire control of the money operations of the new government. He established the Bank of North America in 1782, and in supplying the army in 1781 issued his own notes for over $1,000,000, which were finally repaid. He resigned in 1784, declining in 1788, when senator, the secretaryship of the treasury offered him by Washington. From 1789 to 1795 he represented Philadelphia in the United States senate. He, with Gouverneur Morris, sent the first American vessel to Canton in 1784. He lost his fortune by speculation, and was confined in prison for debt during the last years of his life. He died at Philadelphia, May 8, 1806.

Mor'ris, William, an English poet, was born near London in 1834. Educated at Oxford, he became intimate with the painter, Burne-Jones, and studied painting himself. In 1858, appeared his first volume of poems, *The Defense of Guenevere, and Other Poems*, which was scarcely noticed, though the work that will give him a name in the future; his long poem, *The Life and Death of Jason*, in 1867, attracted attention, and *The Earthly Paradise* confirmed his reputation as a poet. His later publications are *Love is Enough*, *Fall of the Niblungs*, and translations from the Icelandic. His socialistic writings and speeches occupied him of late years, to the exclusion of poetry. His name is also identified with the household decorations, wall papers, tiles, and stained glass, manufactured by the establishment founded by him in 1863, and which are well known in all art circles. His lectures on *Hopes and Fears for Art* were published in 1882. He died at London, Oct. 3, 1896.

WILLIAM MORRIS.

Mor'rison, Robert, the founder of Protestant missions in China, was born in Northumberland, England, Jan. 5, 1782. He was sent out in 1807 by the London Missionary society to Macao and Canton. In 1814, he had translated into Chinese and printed the New Testament, and four years later the Old Testament, with the help of an assistant. In 1823, as translator for the East India company, he printed the Chinese dictionary in six volumes, at an expense to the company of $60,000. It was the work of sixteen years, and in working on it he collected a library of 10,000 Chinese books. The dictionary was afterward translated into Japanese. He established an Anglo-Chinese college at Malacca. He visited England in 1824 and presented his Chinese library to University college, London. While acting as interpreter to Lord Napier he died at Canton, China, Aug. 1, 1834. See *Memoirs*, by Mrs. Morrison; *Robert Morrison*, by Townsend.

Mor'ristown, N. J., the capital of Morris county, and a place of much historic interest during the Revolutionary war, is situated in northern central New Jersey, 30 miles west of New York city. It is at a high elevation, and is the home of a number of New York merchants. Here is the famous Ford mansion, occupied by General Washington, and now the property of the State Historical society. It is reached by the Delaware, Lackawanna, and Western railroad. At Morris Plains, near by, is the New Jersey State Lunatic asylum. It is a city of schools, seminaries, hospitals, churches, libraries, banks, etc., and has all the equipment of a growing civic center. Population 11,267.

Morse, Samuel Finley Breese, an American inventor and artist, was born at Charlestown, Mass., April 27, 1791. He graduated at Yale college, and studied painting in England in company with Allston and West. His first success in sculpture, *The Dying Hercules*, brought him a gold medal from the Adelphi Society of Arts. He was president of the

National Academy of Design from 1826 to 1842, and became professor of the arts of design in the University of New York in 1835. On a voyage from Havre to New York, in 1832, the idea of a magnetic telegraph first

SAMUEL MORSE.

occurred to him as the result of his studies in electricity. He made several successful experiments in 1835, working a line of half a mile around his room. He applied to congress in 1837 for aid to build a line from Washington to Baltimore, and tried to obtain patents in England and in France. He struggled on with scanty means, until at midnight, in the last hours of its session, in 1843, congress made an appropriation of $30,000 for the line to Baltimore, which was in working order in 1844. The first submarine telegraph lines were also laid by him in New York harbor in 1842, and in 1843 he wrote to the secretary of the treasury, suggesting a telegraph across the Atlantic. His system was adopted throughout Europe, and every European government honored him with decorations and finally, through the influence of Napoleon III., presented him, as an international gift, in honor of his work, $20,000. Becoming acquainted with Daguerre, in Paris, he learned the new art of taking pictures, and made the first daguerreotype apparatus in America. He died at New York, April 2, 1872. See *Life*, by Prime.

Mor'tar. See ARTILLERY.

Mor'tar. See CEMENTS.

Mor'ton, Levi Parsons, ex-Vice-president of the United States (1889–93), was born at Shoreham, Vt., May 16, 1824. He was first clerk in a country store and then partner in a merchant's firm at Boston. In 1863, he founded banks in London and New York, and for a time was at the head of one of these — the house of Morton, Bliss & Co. In 1878 and 1880, he was sent to congress, and from 1881 to 1885 was minister to France. He was elected Vice-president in 1888, his term ending in March, 1892.

Mor'ton, Oliver Perry, the "war governor" of Indiana, was born in Indiana, Aug. 4, 1823. He studied at Oxford, O., and practiced law in Indiana. In 1860, as lieutenant-governor, he succeeded Governor Lane, in the governorship of Indiana, Lane being elected United States senator. He became famous in the next four years as one of the "war governors," raising

OLIVER P. MORTON.

troops, and borrowing money on his own notes to carry on the state government. He was re-elected in 1864, became United States senator in 1867, and again in 1873. He was influential in congress, serving on important committees and advocating the 15th amendment to the constitution. He died at Indianapolis, Nov. 1, 1877, having been a cripple from paralysis since 1865.

Mosaic (*mo-zā'ĭk*) is the name given to the art of producing designs in colored stones or glass, by the use of small pieces made to fit together, and held in place by cement. The pattern or picture becomes thus practically indestructible. This art flourished during the palmy days of Rome, being used for floors, walls, and ceilings alike. It was revived under the Byzantine empire, especially for churches; and came into great popularity again in Italy during the middle period of the 13th century. In the workshops connected with the Vatican, workmen are constantly engaged in reproducing in mosaic the pictures of world-renowned artists, using not simply marbles of natural colors, but glass and artificial stones, especially prepared and exquisitely tinted for this purpose. Very striking effects are produced by the use of glass backed with gold or silver, or colored like sea shells. Not only have the Russians greatly excelled in modern mosaics, but Americans also, and some of the finest designs ever produced are to be found in American public library buildings, notably at Washington and Chicago. Florentine mosaic, used chiefly for jewelry, personal ornaments, and paper weights, is composed of shells or stones of natural colors cut in much larger pieces than are employed in Roman mosaics. The demand for mosaic work increases every year, and skill in the use of the materials employed will doubtless bring the art to great perfection in our own country.

Mosby (*mōz'bĭ*), **John Singleton,** a noted Confederate soldier, was born at Edgemont, Powhatan county, Va., Dec. 6, 1833. He studied at the University of Virginia, and

was admitted to the bar in 1855. At the outbreak of the Civil war he was practicing law at Bristol, Va. He entered the Confederate army as private, but soon became adjutant in the cavalry service, and by 1862 was colonel, operating an independent command whose special work was the cutting communications between the Federal front and its base of supplies, and capturing exposed cavalry outposts. The swiftness and daring with which Colonel Mosby operated made him greatly dreaded in the valley of the Shenandoah. At the close of the war he returned to the practice of law. He became a Republican and supported Grant for the presidency in 1872. He was appointed by President Hayes consul at Hong Kong in 1878, where he remained on duty till 1885. He was removed by President Cleveland, and returning to the states made San Francisco his home. In 1901, he was appointed United States land agent and assigned to duty in Nebraska.

Moscow (*mos'kou*), a city of Russia, and its former capital, is situated in the center of European Russia, on the river Moskva, 403 miles southeast of St. Petersburg. It covers 40 square miles. The Kremlin (citadel), in the center, is an inclosed space surrounded by walls with eighteen towers, and is the most sacred spot in the Russian empire. All who enter by the "Saviour" gate must bow to the image of the Saviour that stands above it. Inside the walls are three cathedrals, many churches and monasteries, the great tower, four palaces, an arsenal, and the hall of the synod, with a fine library. The cathedrals have fine mosaics and jeweled ornaments and choice pictures, and have been the burial places of several of the Russian czars. The tower, built in 1600, is 270 feet high, commands a magnificent view of the city, and at its foot is the bell called "king of bells." Before the arsenal is a pile of 800 or 900 French cannon, the trophy of 1812. Outside of the Kremlin is the Cathedral of St. Basil (1554), the historical museum, the great bazaar, the university, founded in 1755, with a library of 200,000 volumes, and 4,407 students, and a public museum with fine collections, a picture gallery, and a library numbering over 300,000 volumes. It is the busiest city in Russia except St. Petersburg, and has numerous manufactures of cotton, silk, and woolen goods, leather, tobacco, candles, carriages, pottery, and matches. Its situation in the center of European Russia, between the Baltic and the Black seas, makes it a great commercial market, and it carries on an extensive trade in grain, timber, furs, hides, tallow, tea, sugar, and in the mineral products of the country.

Moscow was first occupied by the Finns, and settled by the Russians in the 12th century. The Mongols sacked the town in 1237 and 1293, but by the 14th century it had become firmly established, and became in 1325 the seat of the church officers for central Russia. The Kremlin was built in 1300 and was walled in 1367. Moscow continued growing in influence and power and in 1462 its prince, Ivan III., took the title of czar of Russia. In 1547, it was burned down, and again in 1571 it was taken and burned by the khan of the Crimea, and otherwise suffered from the Mongols in 1591. St. Petersburg was made the capital of Russia by Peter the Great in 1713, but the old families and the peasantry still consider the holy city of Moscow as the real capital. The city suffered from fires again in 1739, 1748, 1753, and was finally, in 1812, set on fire and burned by its own citizens to save it from being taken by Napoleon. Since then it has been largely rebuilt. Population 988,614.

Moselle (*mō-zel'*), a branch of the Rhine, rises in the Vosges mountains in France. It passes through Luxemburg and Rhenish Prussia and joins the Rhine at Coblentz. It is 315 miles in length, about 100 miles being navigable.

Mo'ses, the great lawgiver and leader of the Hebrews or Israelitish nation, was born in Egypt, probably about the first half of the 14th century, B. C. The Hebrews were at the time under the power of the Egyptians, and lived in the eastern part of the Nile delta. His early life was spent at the court of Egypt, as the adopted son of Pharaoh's daughter, where he became learned in "all the wisdom of the Egyptians." Driven into the wilderness as a consequence of his killing an Egyptian while protecting a fellow Hebrew from his cruelty, he spent forty years as a keeper of flocks, until called back to lead his people out of Egypt. The story of the exodus, and the forty years' wandering in the wilderness, the giving of the law on Mount Sinai, the fixing of the ceremonies of the new race, the patient endurance of their waywardness and fickleness, until his solitary death and the unknown grave in Mt. Nebo, with only a view of the promised land to which he had led his people, are related in the first five books of the Bible, called the books of Moses. See *Moses, His Life and Times*, by Rawlinson, and Graetz's *History of the Jews*.

Mosquito (*mŏs-kē'tō*), a gnat-like, two-winged insect, the female of which punctures the skin of man and animals and sucks blood. The names gnat and mosquito are often used interchangeably, but gnat has a wider scope. The mosquito is a form of gnat, but there are others like the gall-gnat, buffalo-gnat, etc., to which the name mosquito will not apply. The mosquitoes are to be distinguished from all other kinds of gnats by having a fringe of scale-like hairs on the wings, and, in American forms, these are also found on the wing-veins. The female mosquito is the one that sings and bites; the males are said to feed on the sweets of flowers. The apparatus for puncturing the skin and sucking blood con-

sists of six slender pieces, united in a case, and forming a sharp stylet. These pests are distributed not only in tropical and temperate regions but, during the warm season, in Lapland, Siberia, Canada, etc. They abound in regions around the Lake of the Woods and drive hunters, horses, and cattle to distraction with their bites. The life history of the common mosquito is as follows: The eggs, to the number of four or five hundred, are deposited by a single mosquito, in the form of a float or raft, in any standing water. The eggs soon hatch into wigglers, or larvæ, which feed upon decaying matter in the water. The wigglers breathe by an air-tube in the posterior part of the body, and it is necessary for them to come to the surface for air every two or three minutes. The larvæ soon pass into a pupa stage from which the perfect insect emerges. Mosquitoes have unusual interest to medical men, since it has been recently shown that they are connected with the spread of malaria, jungle fever, Roman fever, and yellow fever. The more common mosquito of the genus *Culex*, does not carry malaria, but a closely-related form, with spotted wings, belonging to the genus *Anopheles*, carries the contagion. Malaria is produced by a minute parasite (a protozoon), which lies within the red blood corpuscles. When mosquitoes bite a person affected with malaria, they introduce into their own bodies many of these minute germs with the blood. There, the parasites undergo a secondary development, and, the infected mosquitoes, when they bite again, carry the disease. This is the only known way of transmitting malaria. Yellow fever is also carried in a similar way. The disease is not transmitted by the clothing of the sick, nor by contact with their bodies. To prevent the spread of these diseases it is important to get rid of the mosquitoes. Various means of combating them have been adopted. Draining marshy lands, introducing fish into the water, that feed upon the wigglers, and covering the surface of standing water with kerosene. The latter is the most effective. Oil dropped upon the water will spread as a film over it. When the wigglers come to the surface to breathe, the oil gets into their breathing tubes and they are thereby killed. See Howard's *Malaria and Certain Mosquitoes*, *Century Magazine* (April, 1901); *Mosquitoes* (New York, 1901); Sternberg's *The Transmission of Yellow Fever by Mosquitoes*, *Pop. Science Monthly*, July, 1901.

LIFE HISTORY OF THE MOSQUITO.

(a) Larva. (b) Pupa. (c) Insect emerging. (d) Male Mosquito. (e) Female Mosquito.

Mosqui'to Coast was formerly an independent state under the protection of Great Britain. It lies on the east side of Nicaragua, to which it now belongs. The land on the coast is swampy, but the mountain regions in the interior are healthy. The people are a mixed race, part Indian and part African, and number about 15,000. It was discovered by Columbus in 1502, and claimed by Spain. It was the home of the buccaneers in the 17th century, and subject to Britain from 1655 to 1850. The Mosquito Reserve (assigned to the mixed race of Indians) forms one of the departments of the republic of Nicaragua, and now bears the name of Zelaya.

Moss. See Musci.

Moss'es, a large class of flowerless plants. Found in all climates, they are most abundant in temperate regions and damp places. A moss plant consists of a stem with leaves and roots. Roots will grow out from any part of the plant. The plant produces what are called moss flowers, something like a bud, but which is really an egg cell; from the egg grows another plant, which remains on the parent plant, and which produces spores or seeds, when usually the mother-plant dies. In mountain regions there are thick beds of moss which soak up the rain and often prevent floods. The beds of moss which are seen growing to-day in bogs are the tips of plants which began life thousands of years ago, and which have formed great beds of peat 20 feet thick. There are about 3,000 species of mosses, divided into four orders. "Irish moss" is not a moss, but a seaweed, and "Iceland moss" is a lichen.

Moths, insects closely related to butterflies, but flying mostly at night. They usually have thread-like or feathery antennæ, and hold their wings nearly flat when resting; butterflies usually hold theirs erect. Like butterflies, their wings are covered with scales, and, therefore, they belong to the order *Lepidoptera*. There is a general impression, that moths are smaller and more somber than butterflies, and while this is true in reference to many moths and "millers," nevertheless, some of the largest and most beautiful of the Lepidoptera are moths. The Cecropia and Promethea moths are large and beautiful forms with bright colors and eye-spots on their wings. The Luna moth, of a pale green color, with eye-like spots having a transparent center on each wing, is especially attractive. The hawk moths, coming from larvæ like the tomato worm, are examples of large moths. Among the best known moths

are the silkworms — whose cocoons supply most of the silk of commerce. Some of the smaller forms are very destructive to furs, woolen cloth, and other fabrics. The larvæ of others are destructive to crops and trees. The armyworm, cottonworm, and tent caterpillars are larvæ of moths. See ARMYWORM, COTTONWORM, CATERPILLAR.

Mo'tion, Laws of. By these reference is generally had to the three great generalizations in which Newton described the effect of forces upon bodies. See DYNAMICS where these laws are stated. See also *Newton's Laws of Motion*, by Professor P. G. Tait (London 1899), for an extraordinarily clear, brief, and elegant discussion of this subject.

Mot'ley, John Lothrop, an American historical writer, was born at Dorchester (now part of the city of Boston), Mass., April 15, 1814. As a boy he had Bancroft for a teacher. His higher education he obtained at Harvard college and in German universities, where he made a friend of Bismarck. His first great work, the *History of the Dutch Republic*, was the result of nearly ten years' labor, much of the time being spent in Berlin, Dresden, and The Hague, in searching for materials. It was translated into Dutch, French, German, and Russian, and established his fame. It was published in three volumes in 1856. His room is shown to visitors in the queen's palace at The Hague, where he worked by royal invitation. *The History of the United Netherlands* followed, the first two volumes being published in 1860, and the last two in 1868. His last work was the *Life and Death of John Barneveldt*, which is still another contribution to the history of Holland. His plan of historical writing embraced a *History of the Thirty Years' War*, which was not finished. He was also a contributor to the *Atlantic Monthly*, and his letters to the *London Times*, during the Civil war, were effective in giving to the English people an understanding of the real question involved. He was United States minister to Austria from 1861 to 1867, and in 1869–70 minister to England. He died at the home of his daughter, in Dorsetshire, England, May 29, 1877. See *Memoir*, by Oliver Wendell Holmes; *Letters*, edited by George William Curtis.

Mo'tor is the name applied to any mechanical device by means of which energy is converted into motion. A windmill, used for driving a wheel or working a pump, is sometimes called an aeromotor. A machine by which the pressure of water in city mains is made to operate mechanical devices is usually called a water motor. Motors for the use of compressed air have of late years been much used, especially for the propulsion of street cars. But the name is now most frequently applied to devices for the conversion of static into dynamic electricity. Motors operated by electricity have been devised to propel everything from a bicycle to a locomotive. Electric power is sometimes conveyed to the motor from a waterfall, and sometimes from a storage battery. In any simple electric motor one finds a field magnet consisting of various coils of insulated wire on soft iron cores. These are connected by a yoke; and lines of force are developed around the pole pieces when a current of electricity is run through the coils. Within these lines of force rotates the armature. Of late, through improved devices, power is conveyed long distances, as from Niagara Falls to Buffalo; and power is conveyed to thousands of motors which operate innumerable mechanisms at a distance from the source. The discovery that natural forces can be made to store electric forces which may be in turn reconverted into dynamic electricity at the other end of the wire by means of an electric motor, is one of the greatest discoveries of the 19th century.

Mo'tor Or'gan (in plants), a term applied to a portion of the leafstalk (petiole) which is sensitive to certain stimuli (see IRRITABILITY) and has a special structure enabling it to curve easily. Motor organs are most perfect in the bean family and oxalis family, but exist also in some spurges (*Euphorbia*), the common mallow (*Malva rotundifolia*), and velvet leaf (*Abutilon Avicennæ*). To the eye the motor organ is usually of a different color from the rest of the leafstalk, and either larger or smaller. If the leafstalk is long the motor organ will be at the base; if short the whole stalk may be a motor organ. In compound leaves there may be motor organs at main and secondary (and even at tertiary) petioles. In contrast with the rest of the petiole the woody parts of the motor organs are gathered near the center, and the whole of the surrounding tissue is made of thin-walled cells. When their turgor (which see) increases on one side and decreases on the other the motor organ becomes curved carrying the leaves into a new position. See article on MOVEMENTS.

Mott, Mrs. Lucretia Coffin, an American quakeress, was born at Nantucket, Mass., Jan. 3, 1793. She became a preacher and traveled through New England, Pennsylvania, Maryland, and Virginia, preaching the Quaker doctrines and opposing intemperance and slavery. She was active in organizing the anti-slavery society at Philadelphia in 1833, and proceeded as a delegate to the world's anti-slavery convention at London in 1840. She was also prominent in woman's rights assemblies. She died Nov. 11, 1880.

Mould (among plants). See PHYSOMYCETES.

Mound Build'ers, the name given to the race whose works, known as earthworks, are found in America, largely in the shape of mounds. There are many theories in regard to them, some believing them to be the same

as the American Indians, the ancestors either of the more civilized Indians found in the southern states, or of the Aztecs in Mexico, while others consider them to have been a superior race, of whom nothing is known, except these curious remains. From the contents of the mounds they (their builders) seem to have been passing from the stone age to the metal, familiar with copper, but possessing chiefly weapons and tools of stone. Some of the mounds seem to have been used as burial places, and others as temples. They are found in the Mississippi valley, and in other parts of North America, but most extensively in Ohio, Indiana, Illinois, and Missouri. They are mounds varying from 6 to 25 feet in height, though some of the temple mounds reach higher; one in Illinois is 90 feet high, and measures 700 by 500 feet at the base. They usually have a ditch around them, and are often in an inclosure, with low earth walls and connecting passages, as one at Newark, O., which covers more than two square miles, and has about 12 miles of embankments from 2 to 20 feet in height, and another at Marietta, O., covering a large square, with double walls inclosing a passage to the river. When used as burial places the mounds rarely contain more than one skeleton. There are also curious figures of animals; one in the form of a serpent, 1,000 feet long and about five feet high, was discovered in Adams county, O. The period when the mounds were built is variously estimated. The Indians found in North America, when settled by Europeans, were very much behind the mound builders in their arts of living, judging from the remains found. The large trees growing on the mounds are another indication of their age; and the fact that they are never built on the lowest formed river terraces, is thought to be another proof of their great age, which is estimated at from 1,800 to 2,000 years. See *Ancient Monuments of the Mississippi Valley*, by Squier and Davis; *Antiquities of Ohio*, by Shepherd; *Antiquities of Tennessee*, by Thurston.

Mount Car'mel Pa., a borough in Northumberland county, in eastern central Pennsylvania, 28 miles east of Sunbury. It lies in the anthracite coal region, on the Lehigh Valley and the Philadelphia and Reading railroads. The town has gained about 5,000 inhabitants in the past decade, its present population being 13,179.

Mount Holyoke (*hōl'yōk*) **College**, a college for women at South Hadley, Mass., founded by Mary Lyon. It was chartered in 1836 as Mount Holyoke seminary, and was long maintained under this name as a seminary of high grade. In 1893, it was chartered as Mount Holyoke college, and the institution was placed in respect to educational facilities and requirements on a standing with the colleges for young men. It has a faculty of 60, and the students number 550.

Mount Ver'non, the home and burial place of George Washington, is situated in Virginia, on the Potomac river, fifteen miles below Washington. The estate originally included several thousand acres. The house is of wood, two stories high and 96 feet long, and was built by Lawrence Washington, an elder brother of George Washington, and named in honor of Admiral Vernon, under whom he had served in the West Indies. Washington improved both the house and the grounds. The library and Washington's bedroom are kept as they were when in use by him. He left the estate to a nephew, who sold the house and 200 acres of land, to the Ladies' Mount Vernon association, a society organized to care for it and keep it as a national possession.

Mount Ver'non, N. Y., a flourishing city in Westchester county, southeastern New York, on the Bronx river, fourteen miles north of New York city. It is served by the New York Central and Hudson River, and by the New York, New Haven, and Hartford railroads. The town is prettily situated, and commands a fine view of Long Island sound. It now includes part of the town of Eastchester and the suburb of Chester Hill, and has almost doubled its population in the past decade. It is largely occupied by New York business men as a place of residence. There are many fine churches, schools, libraries, banks, and an opera house. It has a few industries, including manufactures of pens, rubber, jewelry, carriages, etc. Population 20,346.

Mouse, a small gnawing animal closely related to the rat. The common house mouse, originally an inhabitant of Asia, has spread until it is now found round the world. It is so common that its appearance and habits are well known, but it is not so generally known that, besides squeaking, the animal is a musical singer. Its song is rythmical, in a high key, and, as one observer says, "something like a weak-voiced canary bird." Besides the house mice there are various kinds of field and meadow mice. The harvest mouse of Europe is very small, being between two and one-half and three inches long. It lives among grasses and in cornfields, where it builds a globular nest about the size of a cricket ball, in which its young are reared. The American field mouse differs from the house mouse in having a blunt nose, short limbs and tail. When abundant they are great pests to farmers. In 1890, the wheat crop in South Australia was almost completely ruined by field mice. The white-footed mouse, or deer mouse, known by its snow white feet, is common in the United States, especially in the west.

Move'ments (in plants). Movement from place to place is possible only to the simpler plants and those living in water or on wet surfaces. To accomplish it, the protoplasm is

extended either into one or more slender threads, called cilia, which bend quickly and act somewhat as oars; or into broad blunt protrusions by means of which the cells creep. (The method of some movements is still unknown.) Movements of larger plants are due to bending. This may be done by unequal growth on different sides or by unequal turgor (which see) on the opposite sides. Motor organs (which see) are regions of the leafstalk specially arranged to permit curvature by the latter method. Movements are usually executed in response to some stimulus, though some seem to be spontaneous. See also IRRITABILITY, CHEMOTAXIS, CHEMOTROPISM, GEOTROPISM, HELIOTROPISM, HYDROTROPISM, PHOTOTAXIS, RHEOTROPISM, and THERMOTROPISM.

Mozambique (*mō-zam-bēk'*), the name given to the northern possessions of Portugal on the eastern coast of Africa. They include Mozambique, Zambezia, and Lourenço Marques, and extend from Cape Delgado to Delagoa bay, 1,300 miles. The Zambezi is the principal river, and forms the southern boundary of Mozambique proper, its inland border extending to Lake Nyassa. The coast is low and swampy, but the interior has well-wooded plains, with valuable timber. The soil is fertile and produces corn, rice, cotton, cocoanut, and india rubber. The country is rich in minerals, but mining has not been extensive. The capital is Mozambique, built on a coral island near the mainland. The Mozambique company administers, besides Mozambique, the Manica and Sofala region.

Mozambique Channel lies between the island of Madagascar and the east coast of Africa. It is about 400 miles wide, and 1,000 miles long.

Mozart (*mo-zart'*), **Wolf'gang Amade'us Chrysos'tom,** the great musician, was born at Salzburg, Germany, Jan. 27, 1756. When only six years old, his father took him and his sister on a musical tour through Europe. In Bologna, then the great centre of music in Italy, the Philharmonic society elected him for membership when only fifteen, in spite of its rule that no one under twenty should be admitted. The Easter music in the Sistine chapel was jealously guarded, and no copy allowed to be made, but young Mozart, hearing it once, wrote it out from memory. In 1781, he lost his position in the court of the archbishop, with whom he had gone to Vienna. He produced soon after two operas, one of them, *The Marriage of Figaro*, which created a furore, and he was commissioned to write an opera for the theatre in Prague. The summer-house where, and the little stone table on which, he wrote this opera, *Don Giovanni*, are still shown in the gardens at Prague. The great success of this work made it impossible for the court to overlook his merits longer, and he received an appointment by the emperor, with a small salary, his duty being to supply the dance-music at the imperial balls. He struggled with debt, a false loyalty preventing him from leaving the service of the emperor when offered a better position in Prussia. A friend, a theatre manager, in financial difficulties, induced Mozart to come to his aid with a new opera, and he began in March, 1791, his *Magic Flute*. It was produced in September, and made the fortune of the lucky manager. While at work on this opera, a stranger visited him and commissioned him to write a requiem mass, to be finished in a month. He imagined there was something mysterious about the order, and said he was writing it for himself. He was really dying, and on Dec. 4, 1791, when a few friends met to rehearse the part of the work that was finished, he was unequal to the effort, though even when unconscious seeming to be occupied with his work. He died that night at Vienna, and was buried in the churchyard. When his wife tried to find the grave a few days after, no one could tell her where it was. Many years after his death, Vienna honored him with a monument. Mozart wrote 624 compositions. In opera and symphony he is second to none. His three great operas, *Don Giovanni*, the *Magic Flute*, and *Figaro*, still hold their place on the stage, and three of his forty-one symphonies will always be admired as long as music exists. See *Life*, by Otto John, translated by Townsend.

Mudfishes, a small but important group of fishes that possess lungs as well as gills. They are also called lung-fishes, and form a natural order — the *Dipnoi* or double breathers. In having lungs they approach the class of amphibia just above the fishes. They are descended from a very ancient stock of fishes, representatives of which are found in the mesozoic rocks. There are only three varieties now living: the ceratodus, of Queensland, Australia; the protopterus, of the rivers of tropical Africa; and the lepidosiren, of the Amazon and its tributaries. They are all fresh-water fish of an eel-like form, and attain a length of three to six feet. Ceratodus is the largest, reaching a weight of twenty pounds. Its flesh is highly esteemed as food. It feeds on plants and the insects found upon the leaves. Protopterus is smaller. It feeds on insects, frogs, and smaller fishes. At the approach of the dry season, it burrows in the mud, and forms around itself a capsule of earth. This is lined internally with a moist slime secreted by the glands in the skin. Within this case the fish lies in a dormant condition, feeding upon fatty material stored up mainly in the tail. These capsules of earth have been dug out, and the living fish safely transported to Europe and the United States. They are revived by immersion in the water. The lepidosiren is not so well known as the other two forms.

Muhlenberg (*mu'len-berg*), **William Augustus,** an American divine, noted as a hymn-writer, was born at Philadelphia, Sept. 16, 1796. He graduated at the university of Pennsylvania in 1814, and became an Episcopal clergyman. Soon after becoming rector of a New York church, he set about getting funds to found St. Luke's hospital, and it was due to his untiring efforts that the present great hospital on Fifth avenue, New York, was built, Dr. Muhlenberg becoming its superintendent. He was the author of the well-known hymn, *I Would Not Live Alway*, and edited several collections of church music. He died at New York, April 8, 1877.

Mulat'to. See NEGRO.

Mul'berry, species of Morus, a genus which belongs to a family closely related to the nettle family. About 100 species of mulberry have been described, all of which are trees of the temperate regions of the northern hemisphere. In the United States, the mulberry is known almost entirely as a fruit-bearing tree, although it is not cultivated in any general way. In the Old World, mulberries are grown as food for silk worms, as well as for the fruit. The silk worm mulberry is *M. alba*, and the chief fruit-producing mulberry is *M. nigra*. *M. alba* is a native of China, and has been cultivated from the earliest times in connection with the silk-worm industry. The fruit is small and white or violet. The black mulberry is a native of Asia, and is cultivated chiefly in the Old World for its fruit, which is large and fleshy, mostly dark colored. The native red mulberry of the United States is *M. rubra*, which grows mostly in rich soils and bottom lands.

Mulhausen (*mül-how'zen*), a city of Alsace-Lorraine, Germany, on the Ill and the Rhône, and the Rhine canal, 20 miles northwest of Basel. Its cotton manufactories employ 75,000 hands, and it has printing and dye works for cotton, linen, calico, wool, and silk fabrics, chemical, and iron-works. The city was founded before A. D. 717, and became a free imperial city in 1273. It became a part of France in 1798, and after 1829 began to be a noted manufacturing center. Its arrangements for housing and caring for the working-classes are remarkably good. Since the war of 1870–71, Mülhausen has belonged to the German empire. Population 82,986.

Mullein (*mül'lin*), the name of species of the genus Verbascum, which belongs to the figwort family. The genus contains about 125 species, all of them natives of the eastern hemisphere. About five species have become naturalized in North America, the most conspicuous of which is the common mullein (*V. thapsus*), an erect, stout, simple plant, which is densely woolly all over, and is exceedingly common in fields and waste places. It is a native of Europe and Asia, and is said to have received in England no less than 40 common names. The next best-known naturalized species is the moth mullein (*V. blattaria*), with a slender, merely pubescent stem, and a loose cluster of yellow or white flowers with brown marks.

Muller (*mül'ler*), **Johan'nes,** a distinguished German physiologist, was born at Coblentz in 1801, and died at Berlin in 1858. He became professor of physiology at Bonn, in 1826, and at the university of Berlin in 1833. He is a monumental figure in the history of physiology. By wide observation and experiment he founded comparative physiology. He was the trainer of some of the greatest physiologists, as Ludwig, Du Bois-Reymond, Helmholtz, and others. In his work he recognized the close connection between physiology and psychology, and thereby made a beginning in physiological psychology. His work was so remarkable that he gained for himself the title of the "greatest physiologist of modern times." He was myriad-minded, and later in life gave his attention to zoology, winning in that field the title of the "greatest morphologist of modern times." His handbook of physiology (1833) is unsurpassed in the method of handling the subject. His anatomy of some of the lower fishes (myxinoids) is remarkable for accuracy and for his appreciation of the meaning of his discoveries.

Mul'let, a food fish found in tropical and temperate waters. On the American coast they range as far north as Cape Cod. The mullet family contains mostly sea-fishes, but the representatives ascend streams, and a few forms are permanent residents of fresh water. They feed at the bottom, taking quantities of mud into their mouths, and sifting out the small particles of animal and vegetable matter. The name mullet is also given to a very common sucker of inland streams in the United States. These fish grow to a length of two feet. Their lower fins are of an orange-red color, and they are often called red-horse.

Mu'lock, Miss. See CRAIK.

Mul'ready, William, an Irish landscape and figure painter, was born at Ennis, County Clare, Ireland, April 1, 1786. When a boy he went with his parents to London, and when fifteen began to study at the Royal academy. His genre paintings are the best, such as *Dogs of Two Minds*, *The Barber's Shop*, *Idle Boys*, in his earlier years; and in middle life *First Love*, *The Truant*, and *Seven Ages*. He also worked unweariedly at portrait-painting and at illustrations for children's books, while his illustrations of the *Vicar of Wakefield* are well known. He was careful in drawing and rich in coloring. Mulready died in London, July 7, 1863. See Stephens' *Memorials of Mulready*.

Mum'my, the name given to embalmed bodies. Embalming, so named from the

balm or balsam often used, is the art of preserving the body after death, and was invented by the early Egyptians. This art seems to have arisen from the belief that the preservation of the body was necessary for the return of the soul to the human form after being separated from it for three or ten thousand years. The question of health may also have influenced the Egyptians; and the story of the god Osiris, whose body, destroyed by Typhon, was found by Isis and embalmed by his son Anubis, made it a religious rite. The art appears as old as 4000 B. C. at least, for the bodies of Cheops and others of the age of the 4th dynasty were mummied. One of the earliest embalmments of which we have a record is that of the patriarch Jacob, and the body of Joseph was thus prepared and carried out of Egypt. The process is told by the Greek historians, Herodotus and Diodorus. A scribe marked with a reed pen a line on the left side beneath the ribs, down which line the district ripper, a low-class officer, made a deep cut with a stone knife; he was then pelted with stones and chased with curses. The salter next removed the entrails and lungs, except the heart and kidneys, while a companion took out the brain through the nose. The body was then ready for the salts and spices necessary for its preservation, the quality of which depended upon the sum to be paid. In the case of the wealthy, peculiar drugs were passed through the nostrils into the cavities of the skull; the body cavity was washed with palm wine, filled with myrrh, cassia, and other substances, and the cut sewed up. The mummy was then kept in natron (niter) for seventy days, then washed, bandaged in rolls of linen held together by gums, and set upright in a wooden coffin against the walls of the house or tomb. This process cost a silver talent, worth in our money about $3,725. Using cedar oil was a cheaper method and cost a mina, worth about $1,215.

The poorer classes washed the corpse in myrrh, and salted it for seventy days. When thus prepared and covered with a picture of the dead, and clothed as a laborer in the world to come, the mummy was placed in a costly coffin ready for burial, but often kept sometime unburied — often at home — and even brought at feasts and festivals to remind the guests of the shortness of life. All classes, even criminals, were embalmed; but various other methods were used. Some mummies are found merely dried in the sand, others salted by natron, or soaked in bitumen, often with the skin partly gilded and the fingers cased in silver. So successful were some of these processes, that after 2,000 or 3,000 years the soles of the feet are still elastic and soft to the touch. The sacred animals were also mummied. Probably between 4000 B. C. and 700 A. D., when the preservative process practically ceased, as many as 730,000,000 bodies were embalmed in Egypt, of which many millions are yet hidden. Important finds are made from time to time; as in 1881, when over 30 mummies of potentates, including that of Rameses II., were found together at Deir-el-Bahari. Mummies were used in the 15th and 16th centuries of our era for drugs, and as nostrums against diseases.

Other less successful means of embalming were used by early nations. The Persians employed wax; the Assyrians, honey; the Jews, aloes and spices; Alexander the Great was preserved in wax and honey, and some Roman bodies have been found thus embalmed. The Guanches, the early people of the Canary islands, used a process like the Egyptians; and dried bodies preserved by the air have been found in Sicily, France, England, and America, especially in Central America and Peru. In Burma, the bodies of priests are preserved with spices and honey, and are coated with wax and goldleaf. In Europe, Ruysch and William Hunter put oils into the main arteries; and a new means of embalming was found when Chaussier discovered the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard, and grayish. Arsenic, chloride of zinc, and other substances are now used where bodies are to be kept only for a short time. The latest method generally used in the United States is by passing a fluid into the arteries. See Pettigrew's *History of Mummies*.

Munchhausen (*munk'how-zen* or *mŭnchaw'sen*), **Karl Friedrich Hieronymus, Baron von,** was born May 11, 1720, at Bodenwerder, Hanover, of an old noble family. He served as a cavalry officer in Russian campaigns against the Turks, and died at his birthplace, Feb. 22, 1797. A collection of his marvelous stories, or stories attributed to him, was first published in English under the title, *Baron Münchhausen's Narrative of His Marvelous Travels and Campaigns in Russia*, in 1785. The stories were gathered by Rudolf Erich Raspe, a countryman of the baron's living in England. The book at once became popular and has remained so ever since. Münchhausen's name has become proverbial for wild and impossible exploits and adventures.

Mun'cie, Ind., a fast-growing city in Delaware county, on the White river, in eastern central Indiana, a region producing freely of natural gas, which is largely utilized as fuel by its industries. It is situated 54 miles northeast of Indianapolis. It is served by the Cleveland, Cincinnati, Chicago, and St. Louis, by the Lake Erie and Western, and by the Ft. Wayne, Cincinnati, and St. Louis railroads. Its manufactures embrace pulp and paper works; a flour-bagging factory; glass, nail, and iron works, etc. It has a number of schools, churches, banks, and a good public library. Population 20,942.

Munich (*mū'nik*), the capital of Bavaria, lies on a flat and barren plain, 1,700 feet

above the sea, chiefly on the west bank of the Isar, 272 miles west of Vienna. Seven bridges span the river to the suburbs on the east bank. Munich is one of the handsomest cities of Germany, and perhaps the richest in treasures of art, while itself famous for its school of painting. Within the last two generations it has been decorated with buildings of almost every style of architecture, many of them ornamented with frescoes and sculpture; wide and handsome streets have been built; and the squares and gardens have been adorned with statues and other monuments. Among the main buildings are the Glyptothek, with its fine collection of ancient and modern sculptures; the Old Pinakothek, containing paintings by the old masters, besides thousands of engravings and drawings, and a priceless collection of antique vases; the New Pinakothek, filled with modern paintings; the royal and national library; and the Bavarian national museum. The New Palace includes an older palace and chapel, the Königsbau, in the style of the Pitti Palace at Florence, with Schnorr's frescoes of the Nibelungenlied, and the richly adorned banqueting hall building. Among the gates of Munich the most beautiful are the Gate of Victory, the old Isar gate, and the Propylæa. St. Peter's is the oldest church, built in 1294. The huge brick church of Our Lady is remarkable for its two unfinished towers. St. Michael's contains a monument by Thorwaldsen to Eugene Beauharnais. In the Louis church is Cornelius' fresco of the *Last Judgment*. The university has 202 professors and teachers, and over 4,391 students. The main parks are the Court Garden, the English Garden, and Gasteig promenades. Munich is noted for its stained-glass works, iron, brass, and bell foundries, lithographing and engraving works, and factories of optical and mathematical instruments. There are also very large breweries of Bavarian beer, which produce yearly over 50,000,000 gallons. The chief trade is in grain, and in objects of art.

The name Munich comes from the Monks who owned the site. It really began as a town in 1158, when Henry the Lion established there a mint and a salt exchange. It was fortified in the 13th century. In 1327, the old town was nearly destroyed by fire, and was rebuilt by the Emperor Louis the Bavarian. The true history of modern Munich is the account of its growth as an art center in the 19th century. Population 499,959. See Mrs. Howitt-Watts' *Art Student in Munich*.

Munkacsy, Mihaly (*mŏn-kăch'ē*), a Hungarian painter, was born at Munkács, Hungary, Oct. 10, 1846. His real name was Michael Lieb; and his family, before the revolution of 1848, was one of modest affluence. The father having lost both property and life in the uprisings of that year, the son was apprenticed to a cabinet maker. He was encouraged in his first artistic attempts by Samosy, an artist of some reputation; and, having reached the Vienna academy, he was enabled to study to some purpose under Adam (Franz). He went to Düsseldorf in 1867, and painted there *The Last Day of a Condemned Man*, which at once won him fame. He removed to Paris in 1870, was married in 1874, and built himself an elegant mansion in that city. His best known works in America are *Milton dictating to His Daughters*, and *Christ before Pilate*. He visited the United States in 1886, and painted several portraits of prominent people in New York. His earlier works show the somber effects of his laborious life; his middle period something of the lightness of the Parisian environment; but his greatest fame was won in the third period of his development from the treatment of historic and sacred themes. He died near Bonn, May 1, 1900.

Murat (*mū-rä'*), **Joachim,** king of Naples, was the son of an innkeeper, near Cahors, in France, and was born March 25, 1771. He was at first intended for the priesthood, but the outbreak of the revolution sent him to the army, where he soon rose to the rank of colonel. Attaching himself closely to Napoleon, he served under him in Italy and in Egypt, achieving distinction in many battles. He was made a general of division in 1799, and greatly helped Napoleon on the critical 18th Brumaire by dispersing the council of five hundred at St. Cloud. Napoleon now intrusted him with the command of the consular guard, and gave him his youngest sister, Caroline, in marriage. Murat held his usual post, the command of the cavalry at Marengo, where he covered himself with glory, and in 1801 was named governor of the Cisalpine Republic. When Napoleon became emperor, he continued to command his cavalry, and helped greatly to win the victories of Austerlitz, Jena, Eylau, etc. In 1806, the newly made duchy of Berg was given him, and on Aug. 1, 1808, he was proclaimed king of the two Sicilies, under the name of Joachim I. Napoleon. He took possession of Naples, but failed to secure control of Sicily. He governed well and won the hearts of his subjects. In the Russian campaign he commanded the cavalry, and the army after Napoleon left it. After crushing the Austrians at Dresden, in 1813, and helping to fight the battle of Leipsic, he made a treaty with Austria, and a truce with the British admiral, but as soon as he heard of Napoleon's return from Elba, he began a hasty war against Austria. He was twice defeated at Ferrara and Tolentino, and with a few horsemen made his way to Naples. Here he found the country in a state of insurrection, and at once proceeded to France. After the overthrow of his chief, he took refuge in Corsica. From here he went with a few followers to the coast of Calabria, and proclaimed himself king, but was soon taken prisoner, tried by court-martial, and shot at Pizzo, Italy, Oct. 13, 1815. Of his two sons,

the elder, Achille Napoleon, went to America, married a niece of Washington, and settled in Florida; the younger, Lucien Charles Napoleon, became a French senator and ambassador under Napoleon III. See Macirone's *Fall and Death of Murat.*

Muravieff (*mō-rä-vyĕf'*), Count **Michael,** was born in 1845, and died at St. Petersburg, June 21, 1900. He was descended from a long line of distinguished ancestors; educated at Poltava and Heidelberg; attached to the Russian embassy at Berlin when under twenty years of age, and in diplomatic service until he became minister of foreign affairs at St. Petersburg in 1897. He had resided as the representative of the czar at Stockholm, The Hague, Paris, and Copenhagen, as well as in Germany. He was passionately devoted to the interests of the czar, and was in consequence distrusted by foreign powers. He died soon after he had reached the summit of his power.

Murchison (*mur'ki-son*), Sir **Roderick Impey,** Scottish geologist and geographer, was born at Tarradale, Ross-shire, Scotland, Feb. 19, 1792. He studied at the Military college, Great Marlow, and entered the army at an early age. He served as an officer in Spain and Portugal, but left the army in 1816. He then studied and traveled in various parts of the globe. He found the same rock strata underlying the red sandstone of mountainous regions of Norway and Sweden, in the distant provinces of the Russian empire, and also in America. This gave him the clew to the discovery of the Silurian system, and a wide reputation as a geologist. He explored several parts of Germany, Poland, and the Carpathians; and in 1840–45 carried out a geological survey of the Russian empire. Struck with the similarity between the rocks of the Ural mountains and the Australian chain, Murchison, in 1844, first foretold the discovery of gold in Australia. Perhaps no man of his time did more to encourage geographical science, and kindle the spirit of adventure among those engaged both in arctic exploration and in African discovery. He was a member of many scientific societies, was knighted in 1846, became a baronet in 1863, and in 1855 was made director of the Royal School of Mines. His chief works are, *The Silurian System,* and *The Geology of Russia in Europe and the Ural Mountains.* Murchison died Oct. 22, 1871. See his *Life,* by Professor Archibald Geikie.

Murcia (*mur'shi-ä*), an old city of Spain, on the Segura river. It is an old-fashioned Moorish place, surrounded by gardens of mulberry, orange, fig, palm, and other fruit trees. The main buildings are the bishop's palace and the cathedral, begun in 1353. Silks, saltpeter, gunpowder, soda, musical instruments, and glass are manufactured here. Fruit-growing, the preparation of olive-oil, and esparto-weaving also flourish. Alfonso X. took the city from the Moors in 1263. An earthquake almost destroyed it in 1829, and it was captured by Spanish rebels in 1843. Population 108,408.

Mur'doch, James Edward, an American actor, was born at Philadelphia, June 25, 1811. He first appeared on the stage in his native city. In 1838, he supported Ellen Tree in leading characters at New York. He left the stage in 1842 to teach elocution. He also lectured on Shakespeare. In 1845, he again became an actor, appearing at New York as "Hamlet" and afterward toured in Canada, California, and England. During the Civil war he gave readings throughout the North in aid of the sanitary commission, devoted himself to the care of sick and wounded soldiers, and served for a while on General Rousseau's staff. Together with William Russell he published *Orthophony, or Culture of the Voice.* After the war, Mr. Murdoch lived at Philadelphia, and died at Cincinnati, May 19, 1893.

Mur'dock, William, the inventor of gas used as a light, was born Aug. 21, 1754, near Auchinleck, Ayrshire, Scotland. He worked under his father, who was a millwright and miller, till he was twenty-three. He then entered the employment of a Birmingham house and showed such marked ability that he was sent to Cornwall to superintend the setting up of mining engines there. In 1784, he built the model of a high-pressure engine to run on wheels. His work at Cornwall was hard, yet up to his forty-fourth year his wages were not more than $5 a week. Murdock's inventive brain was never idle; he introduced labor-saving machinery of various kinds, and an oscillating engine of a pattern still in use. His investigations in the distillation of coal gas began in 1792, when he lighted his offices and cottages by this means. But he reaped little profit from this useful invention. Murdock died at Birmingham, England, Nov. 15, 1839.

Mur'free, Mary Noailles, whose fame as a writer was gained under the name of "Charles Egbert Craddock," was born near Murfreesborough, Tenn., at a point where some of the hardest fighting occurred in the battle of Stone River. The fortunes of her father, a successful lawyer, were wrecked by the war. The desire to write came to her naturally, as both her father and brother had written for the magazines and reviews. Her first story, which appeared in the *Atlantic Monthly,* was *The Dancin' Party.* "Egbert Craddock" was the name of the hero of her second short story, which was half written when she was about to mail the first part to the publishers. Being at a loss for a pseudonym, she stole that of her hero, with the prefix "Charles." The buildings at Miss Murfree's birthplace, the scenes of parts of *Where the Battle was Fought,* were riddled by shot and shell at the battle of Stone River. This is a novel of

great and picturesque power, though *The Prophet of the Great Smoky Mountains* is held to be her best work. *In the Tennessee Mountains* is a collection of eight stories. *Down the Ravine* professes to be a young people's story, but no one is too old to be entranced by its sketches of scenery in the Cumberland mountains and the picture of the "powerful peart" little sister Tennessee. Miss Murfree puts her heart into her work. Her later books include: *The Juggler*, *The Phantoms of the Footbridge*, and *The Mystery of Witch-face Mountain*. In a private letter she says that "nothing of value can be done without the most zealous work in aid of whatever natural gifts one may possess."

Mur'freesbor'ough, from 1819 to 1826 the capital of Tennessee, is 33 miles southeast of Nashville, and has several mills and factories. Close by, the bloody battle of Stone River was fought, Dec. 31, 1862, and Jan. 2, 1863, between Generals Rosecrans and Bragg. The Confederate army was forced to retreat. The losses on both sides, in killed and wounded, were nearly equal — Federals, 9,511; Confederates, 9,236. Population 3,999.

Murillo (*mū-rilʹō*), **Bartolome Esteban,** a famous Spanish painter, was born of poor parents at Seville, Spain, and baptized Jan. 1, 1618. He had a little schooling, and was then placed with a relative who was an artist, to study painting. He saved a little money from the sale of his first rough and stiff religious pictures to the friars of Seville, and went to Madrid at the age of twenty-four. He was kindly noticed by his celebrated townsman Velasquez, and through his influence was enabled to study the great Italian and Flemish masters in the royal collections of paintings. Velasquez wished him to go to Rome, and offered him letters from the king, but Murillo determined to go back to Seville, where he settled in 1645. Here he painted eleven large and remarkable pictures for the convent of San Francisco. At once he won fame; had more orders than he could well fill, and was acknowledged as the head of the school there. In 1648, Murillo married a woman of fortune, and his house became a center of taste and fashion. About this time he passed from his first or "cold" style — dark with decided outlines — to his second or "warm" style, in which the drawing is softer and the color better. Of the second style, good examples are, *St. Leander*, the *Nativity of the Virgin*, and *St. Anthony of Padua*. In 1656, he was at work on four large pictures in the form of a half circle, which are the first examples of his third or "vaporous" style, the outlines vanishing in a misty blending of light and shade. In 1660, he founded the academy of Seville; and was its president for a year. After this, appeared Murillo's most brilliant paintings. Of the eleven pictures painted between 1661 and 1674, for the almshouse of San Jorge, eight are held to be his masterpieces. Among them are *Moses striking the Rock*, *Abraham and the Angels*, *The Miracle of the Loaves and Fishes*, *St. Peter released from Prison*, and *St. Elizabeth*. His famous picture, *The Conception*, now in the Louvre at Paris, was sold in 1852 for $120,000. In 1681, he went to Cadiz, and while there fell from a scaffold when painting an altar-piece in the church of the Capuchins. He went back to Seville and died from his injuries, April 3, 1682. Murillo's pictures are in two groups — scenes from low life, gypsies and beggar children (mostly painted in early life), and Scripture and religious works. His pictures show great technical skill, truth to nature and sentiment, while as a painter of the texture of human flesh he has never been equaled. See Miss E. E. Minor's *Murillo*, and C. B. Curtis' *Velasquez and Murillo*.

MURILLO.

Mur'ray, Lind'ley, an American grammarian, was born at Swatara, Lancaster county, Pa., April 27, 1745. He was educated at Philadelphia at a school conducted by the Friends. His father having removed to New York, he was placed in a counting room there; but he ran away in order to pursue his studies at school in another state. He was later admitted to the bar, but during the Revolution was engaged in business in New York, where he rapidly acquired a fortune. In 1784, he retired from mercantile life, going to England where he purchased an estate and devoted himself to literary pursuits. His *English Grammar*, issued in 1795, was received with enthusiasm, and his *English Reader* was used upon both sides of the Atlantic. These books retained their unbounded popularity in schools for fifty years or more. He died at Holdgate, England, Feb. 16, 1826.

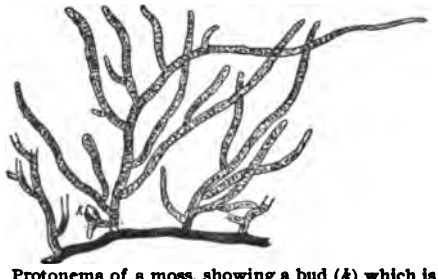
Mur'ray River, the chief river of Australia. It rises in the Australian Alps, flows northwest along the frontiers of New South Wales and Victoria, and in South Australia passes southward through the shallow Lake Alexandrina toward the sea at Encounter bay, a distance of 1,120 miles. It is navigable for small steamers to Albury, 190 miles northeast of Melbourne, but its mouth cannot be entered by ships of any size. Its main branches, the Lachlan, Murrumbidgee, and Darling, are themselves large rivers.

Muscat (*mus-katʹ*), capital of the independent state of Oman, or Muscat, in south-

eastern Arabia, stands in a narrow rocky cove that opens out into the Indian ocean on one side, and on the other is the outlet of a pass into the interior. It is surrounded by a wall and defended by forts on the rocky heights above. It has narrow, uncleanly streets, and is very hot in summer. Its position makes it of great importance for the trade between eastern Arabia, Persia, India, the west coast of Africa, and the Red Sea. Its chief exports are pearls and fish, in which the waters of the coast are very rich, together with salt, dates, drugs, dyestuff, and horses. Although a very old place, Muscat was small and unimportant until the Portuguese took possession of it in 1508. Under their rule, lasting 150 years, it became a flourishing trading town. It was afterward ruled by native princes, called imams. The Muscat imams also ruled Zanzibar and other places in Africa, but lost these territories in 1856. Population 40,000.

Muscatine (*mus-ka-tēn'*), **Ia.,** is situate on the west bank of the Mississippi, built mostly on rocky bluffs, where the river makes a great bend to the south, 211 miles by rail southwest of Chicago. It has a large trade by river and rail, and has extensive pearl button manufactories, employing over 2,000 people; also furniture factories, flour and lumber mills. It was founded in 1836, and became a city in 1853. Population 14,073.

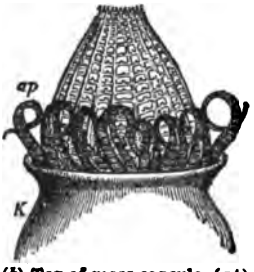
Musci (*mŭs'sī*), one of the two great groups of Bryophytes, commonly known as



Protonema of a moss, showing a bud (*k*) which is to give rise to the leafy branch.

mosses. The numerous species are adapted to all conditions, from submerged to very dry, and are most abundantly displayed in temperate and arctic regions. They have great powers of vegetative multiplication. In consequence of this they form the well-known thick carpets and masses, and the bog mosses often completely fill up bogs or small ponds and lakes with a dense growth which dies below and continues to grow above. These bogs are sometimes called "quaking bogs" or "mosses," and furnish very treacherous footing. When the ordinary spore of a moss germinates it produces at first a little green branching filamentous body resembling an alga, and called the "protonema." Upon this prostrate protonema buds arise, which develop into the erect leafy branches that represent the ordinary moss plant. These leafy branches bear the sex organs (antheridia and archegonia) usually at their summits. In the archegonium the egg is fertilized, forming the oospore. When the oospore germinates, it forms a body which grows downward into the leafy branch for anchorage, and also grows upward in the form of a stalk bearing a spore case. This anchored leafless body is the sporophyte, and is very commonly called the "moss fruit," although it is in no sense a fruit. The protonema and the leafy branches bearing sex organs constitute the gametophyte (See ALTERNATION OF GENERATIONS). This peculiar leafless sporophyte of the moss is usually distinguished from the leafy sporophyte of ferns and seed-plants by being called a "sporogonium." The most complex structure of mosses is the spore case or capsule. Usually perching upon the top of a young capsule is a loose conical cap or hood, known as the "calyptra." This calyptra is the enlarged and ruptured archegonium, which has been carried up by the development of the capsule. Removing the calyptra a small lid ("operculum") is discovered, which upon being removed reveals the rim of the urn-like capsule. This rim is frequently beset by numerous beautiful hair-like or tooth-like processes, which extend toward the center and form what is called the "peristome." These peristome teeth are of service in discharging the spores. Running through the midst of the capsule is a central axis of sterile tissue known as the "columella." Mosses are divided in two great groups: (1) sphagnum mosses, which are large and pallid bog mosses, found abundantly in marshy grounds, especially in temperate and arctic regions, and are conspicuous peat formers; (2) true mosses, which contain the great majority of the mosses, and are the representative Bryophytes, growing in all conditions of moisture from actual submergence in water to dry rocks.

Leafy branches of a moss bearing the stalked capsules (Sporophytes), the one to the left still retaining the hoodlike calyptra.



(*k*) Top of moss capsule, (*ap*) showing the peristome teeth.

JOHN M. COULTER.

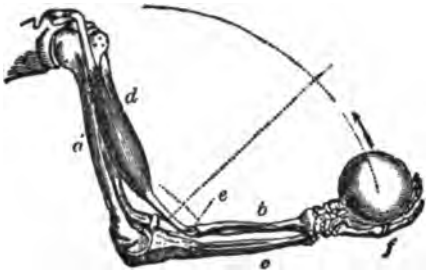
Muscle (*mus''l*), an animal tissue endowed with the power of contraction. It is the part called flesh or lean meat in the higher animals. Through its action motion and locomotion are accomplished in the animal king-

dom. Muscles have not been developed in the simple microscopic animals, like the amœba and its relatives, and, therefore, their movements are not dependent upon muscles, but upon the powers of the protoplasm of which they are composed. In that, however, lies the germ from which muscular tissue is developed. Muscles are composed of modified protoplasm, in which the power of contraction has been highly exalted, while the other qualities of protoplasm are undeveloped or held in check. Muscles first make their appearance in animals of the grade of hydra and the jellyfishes, but, in them, they are imperfectly developed. In all animals of a higher grade than jellyfish muscular tissue is fully developed. It arises in the middle germ layer (*mesoblast*). In its formation the cells elongate into fibers.

As an example of muscular tissue, take the muscles of the arm. These are bundles of flesh, which can be felt under the skin running lengthwise in the arm. Each muscle is covered with a smooth shining membrane, and is made up of a number of bundles also covered with a thin membrane. These bundles are further subdivided into smaller ones, and the microscope shows that these are made of thread-like fibers lying side by side. All are surrounded by sheaths and united together. The microscopic fibers are crossed by stripes, and this kind is called *striated* muscular tissue. It is the kind usually controlled by the will and is, therefore, called voluntary. There is another variety of muscular tissue found in the walls of the alimentary canal and blood vessels (and in other situations), the action of which is not directed by the will, and, therefore, called involuntary. Under the microscope, this is made up of spindle-shaped cells each with a round nucleus in the middle. These are not striped and this kind is called *smooth* muscular tissue. The muscles of the heart are striated, but are branched and different from ordinary muscles. Therefore, we have the three varieties — striated, smooth, and heart muscle.

There are about four hundred muscles in the human body, most of them in pairs. All receive distinct names, and are connected with nerves and blood vessels. The blood vessels, for their nourishment, form a network around the fibers, while the nerves which control them form a closer connection. Most of the muscles attached to the bones have an enlarged middle (belly), and two ends tapering off into tendons, by means of which they are grown to the bones. The bones are roughened where the muscles are attached. The more rigid attachment is called the *origin*, and the more movable one the *insertion* of the muscle. Other muscles are flat and some surround cavities. They are named in various ways, according to their position, as the temporals, in the region of the temple; the pectorals, on the chest; the abdominals, etc.; from their direction, as a rectus, or straight muscle, an obliquus, or oblique muscle; from their uses, as flexors, which bend a joint; extensors, which extend it; levatores, which lift, etc.; according to attachment by tendons, as sternomastoid, mylohyoid, etc., and also in other ways.

The parts of the skeleton that move usually act as levers. The illustration shows, for example, the chief muscle which bends the



lower arm upon the elbow joint as a fulcrum. This muscle is a flexor, as it flexes the arm; its origin is at the shoulder, where it has two heads, and is, therefore, called the biceps; its insertion is on one of the bones of the forearm. The muscle which extends the arm is not shown in the illustration. It should be kept in mind that the action of a muscle is to contract not to expand. In contracting, it gets thicker and shorter, and it returns to its original state of extension. Other muscles perform the contrary action. Ordinarily muscles contract in direct response to nerve stimuli, but many causes influence them, such as their condition of nutrition, mental states, etc. A good illustration is found in the muscles of the face. They vary with the emotions and mental states, and the expression of the face is the result of the action of a number of muscles.

Mu'ses, in Greek mythology, goddesses included in the first place among the nymphs, but afterward held to be quite distinct from them. They had the power of inspiring song, and so poets and musicians were considered their pupils and favorites. They were first honored by the Thracians, and as this people first lived in Pieria, around Mt. Olympus, the Muses were called Pierides. There were at first three in number, though Homer sometimes speaks of a single Muse, and once refers to nine. This last is the number given by the poet Hesiod, who also gives their names; Clio, the muse of history; Euterpe, of lyric poetry; Thalia, of comedy; Melpomene, of tragedy; Terpsichore, of choral dance and song; Erato, of the poetry of passion; Polyhymnia, of hymns; Urania, of astronomy; and Calliope of epic poetry. They were usually said to be the daughters of Zeus and Mnemosyne. Homer speaks of them as the god-

desses of song, and as dwelling on the top of Mt. Olympus. They were also called the companions of Apollo, singing while he played on the lyre at the banquets of the gods. They were said to have won victories over the sirens in musical tournaments. Their worship among the Romans was merely copied from the Greeks, and never became truly national or popular. The fountains of Aganippe and Hippocrene on Mount Helicon, and the Castalian spring on Mount Parnassus, were the most famous places sacred to the nine Muses.

Mush'room. See BASIDIOMYCETES.

Musk, a substance obtained from the musk-deer (which see) and used as the basis of costly perfumes. That imported from Tonquin, China, is the best. Cheaper varieties come from India and Siberia. It is also used in medicine.

Musk-deer, a small deer separated from others by having no antlers in either male or female. The male has, however, sharp tusks projecting downward from the upper jaw which are used in fighting. These animals inhabit the high plateaus of Central Asia, usually living solitary and never in herds. They are shy, feeding mainly at night, and on account of the difficulty of approaching them, they are usually caught in traps. A full-grown specimen is about three feet long and twenty inches high at the shoulders. They vary in color, but are commonly grayish or yellowish-brown, and whitish below. The musk is found in a sac the size of a very small orange, situated on the under surface of the abdomen. The sack contains an ounce or more of the crude musk, which is so powerful in odor as to nearly overcome those who skin the animal and remove the pouch. When fresh, the substance is said to resemble moist gingerbread in color and consistency.

Muskegon (*mus-kē'gon*), **Mich.,** is situate on the Muskegon river, four miles from its mouth, in Lake Michigan. The river here widens into Muskegon lake, the best harbor on the east side of Lake Michigan. Muskegon is 40 miles northwest of Grand Rapids, and manufactures for shipment great quantities of lumber. It has also a number of foundries, machine shops, boiler works, and toy, wooden ware, and piano factories. Muskegon is the seventh largest city in the state, and has a population of 20,818.

Musk'mel'on, various forms of *Cucumis melo*, a genus of the gourd family, and native to southern Asia. The cultivation of muskmelons has become a very important commercial enterprise in North America. There are two general types in the market: (1) the furrowed kinds with hard rind, known as "cantaloupes," and (2) the netted kinds with softer rinds, known as "nutmeg melons." The nutmeg melons are those most commonly seen in the early markets; while the cantaloupes are longer-seasoned varieties. An important strain of the nutmeg type has recently become prominent under the name of "osage melons," which were developed in southern Michigan. Muskmelons are said to be a staple article of food among the inhabitants of Persia, Egypt, and Italy. Muskmelon growing is extensively carried on in the southern states, and the Mississippi valley in general is peculiarly adapted to the industry. However, New Jersey as yet supplies one-half of the market crop. See *Cucumis*.

Musk Ox or **Musk Sheep,** an animal combining characteristics of the ox and sheep.

MUSK OX.

It is now restricted to arctic America north of latitude 60°, but formerly was more widely distributed, and occurred in England as well as in America. Its favorite haunts are the upper tributaries of the Mackenzie river and the region about Great Bear and Great Slave lakes. It is about eight feet long and three feet high at the shoulders, and a full-grown male reaches a weight of four hundred and fifty pounds. It has long, smooth, brownish hair and lighter-colored underwool, the hair being abundant on the sides and the wool more plentiful on the back. The hairy coat is shed during hot weather. The horns meet in the middle of the forehead; they curve downward and outward and the tips point upward. These animals live in herds of twenty or thirty or upward and are hunted for food. The flesh of the males has a flavor of musk. They feed on grasses, lichens, willow shoots, etc.

Musk'rat or **Mus'quash,** a water rat peculiar to North America. Although adapted to an aquatic life, muskrats spend much time on the shores of the lakes and rivers which they inhabit. The animal is the largest of the rat family, being about one foot long, without the tail, which is six or eight inches in length. The latter is different from the tail of any other rat, being scaly and flattened from above downward. The fur is of a dark, glossy brown and is of commercial value. They live in burrows in the bank, with one or more entrances under water. For winter, they build dome-shaped houses of sedges and grasses plastered together with mud. These project above the

surface of the water, but the entrances are underneath. They feed mainly on roots and stems of water plants. The name is also applied to the desman of the Old World and a rat of India. All of these animals have a musky odor.

Mussel (*mus's'l*), the common name for a number of bivalve mollusks. The common mussel of salt water (*mytilus*), living along the shores of the North Atlantic, is often eaten in Europe, but rarely in America. It is abundant between high and low water marks, and is usually anchored by a tuft of yellowish silken filaments (Lyssus) spun from glands in its body. The common fresh-water clam is the fresh-water mussel. These mollusks belong to the group Lamellibranchiata.

Musset (*mü-sā'*), **Alfred de,** was born at Paris, Nov. 11, 1810, the son of an officer in the war office. He was very impulsive from his childhood, and grew up handsome and fascinating, though he kept something of the spoilt child all his life. He thought first of law, next of medicine, then of art, but at eighteen discovered himself to be a poet, and hardly a year later published his *Tales of Spain and Italy*, a volume of unequal verse. He was now a brilliant youth, was warmly received by the circle that eddied around Victor Hugo, and was flattered by society. In 1833, appeared two of his greatest works, the tragical comedies, *André del Sarto* and *Marianne's Caprices*. It was of Marianne that De Musset answered, when asked where he had found her character, "Nowhere and everywhere; she is not *a* woman, she is woman." Next followed the famous poem of *Rolla*. He first met George Sand in the summer of 1833, soon fell in love with her, and the next spring the two made a tour of Italy, where De Musset came near dying from brain fever. Ever after he had times of deep depression. The patronage of the duke of Orleans, the warm friendship of a small circle of friends, and his appointment in 1838 to be librarian at the home office, did something to take him out of himself; but he was always as unsteady in character as in genius, and the feverish activity that sometimes seized him spent itself in splendid plans and unfinished poems. In 1840, his health broke down and he wrote but little. As Heine said, he was "a young man with a splendid past"; he felt himself an old man at thirty. The success of his play *A Caprice*, in 1847, put life into him for a short time. He died at Paris of heart disease, May 1, 1857.

The Night of May and *The Night of October* are perfect and undying lyrics. As a poet of passion he comes close to Byron in power. His plays have not their equals in 19th-century literature for originality, wit, and real dramatic genius. His largest prose work was the famous *Confession of a Child of the Age;* but greater are his short stories and tales, such as *Emmeline, Pierre and Camille, Mademoiselle Mimi Pinson*, and *Margot*. De Musset's whole work fills but ten small volumes, but it is not too much to say that they include some of the finest poetry, the greatest plays, and the best short stories in French literature.

Mustard, species of Brassica, a genus belonging to the mustard family. The genus contains about 100 species of herbs, natives to north temperate regions. To the same genus belongs the cabbage, with its cauliflower and kale varieties, rape, rutabaga, common turnip, etc. The true mustards are *B. alba* (white mustard), *B. nigra* (black mustard), and *B. juncea* (Chinese mustard). Table mustard is the flour formed from grinding the seeds, mostly from black mustard, though the white and Chinese mustards are also used. The white and black mustards often become widely distributed weeds. The large, soft, basal leaves of these forms are also frequently used for "greens."

Mutualism (*mū'tu-al-ism*), (in plants), that form of symbiosis in which the two plants are of mutual benefit. By many this condition is thought to be illustrated by the lichens, the algæ and fungi constituents being thought to be mutually helpful. See SYMBIOSIS.

Mycelium (*mi-sē'li-üm*), (in plants), the ordinary body of a fungus, consisting of branching colorless threads more or less interwoven. Sometimes the threads are so loosely interwoven that the mycelium resembles a delicate cobweb; at other times the threads are so closely interwoven that the mycelium becomes a felt-like mass. The latter form of mycelium may often be seen upon preserved fruit or jelly, in which case it can be removed like a thick piece of felt. See FUNGI.

Mycenæ (*mi-sē'nē*), a very old city in the northeastern part of Argolis, in the Peloponnesus, built upon a high crag, and said to have been founded by Perseus. It was the capital of Agamemnon's kingdom, and at that time the chief town of Greece. It was destroyed by the people of Argos, and, though rebuilt, never afterward prospered. Its ruins are still to be seen. The most celebrated of them are the "Gate of Lions" and the "Treasury of Atreus." Excavations carried out by Dr. Henry Schliemann brought to light, in 1876, another underground treasury and several ancient tombs, vases, weapons, gold death-masks, and other ornaments of hammered gold. These objects seem to show a type of art coming from Mesopotamia through Phœnicia and Asia Minor, and manifesting little or no trace of Greek tastes or customs. Their date seems to be about that of the Doric invasion of the Peloponnesus.

Myriapoda (*mir'i-ap'o-da*), a class of jointed animals containing the centipedes and thousand-legged worms. The name signifies many-footed. The body is worm-like and

jointed. There is a pair of legs for each joint. The head carries antennæ, jaws, and eyes, and there is no distinction between thorax and abdomen. The Myriapods form a group equivalent, respectively to that of the crustacea, spiders, and insects, and these four classes make up the sub-kingdom Arthropoda. See ARTHROPODA, and CENTIPEDE.

Mycorrhiza (*mī-kō-rī'zd*), (in plants). The name means "root fungus," and refers to the fact that there exists an intimate association between certain fungi of the soil and the roots of higher plants, such as orchids, heaths, oaks, and their allies, etc. The delicate mycelial threads of the fungus spread through the soil, enwrap the rootlets with a mesh of threads, and penetrate into the cells. By this means the fungus obtains food from the rootlet as a parasite, but it is also thought that the fungus threads spreading through the soil are of great service to the host plants in aiding their rootlets in absorbing. If this be true, there is a mutual advantage in the association, for the small amount of nourishment taken up by the fungus is more than repaid by its assistance in absorption. See MUTUALISM.

Myrmidons (*mĕr'mi-dŏnz*), the famous followers of Achilles in the Trojan war. They were an old Thessalian race who colonized the island of Ægina. According to Greek story, Zeus peopled Thessaly by changing the ants into men; hence the myrmidons, which means ants.

Myrrh (*mĕr*), a gum resin produced by a tree growing in Arabia, and also in Somali Land, in Africa. The myrrh tree is small and scrubby, spiny, with whitish-gray bark, with smooth brown fruit about as big as a pea. The myrrh flows from the pores of the bark in oily, yellowish drops, which slowly thicken, harden, and become darker colored. Myrrh was known and highly valued in very early times. It was among the presents which the wise men from the east brought to the child Jesus. Myrrh is sold in tears and grains, or in irregular-shaped and various-sized pieces, yellow, red, or reddish brown in color. It was used by the Egyptians in embalming, and is employed now in medicine. All myrrh comes either from Aden or from Bombay.

Myr'tle, a beautiful evergreen shrub or moderate-sized tree, with glossy leaves, black berries, having a pleasant, spicy odor, and white flowers. This is the common myrtle, which is native to the countries of the Mediterranean. Among the ancient Greeks the myrtle was sacred to Venus, as the symbol of youth and beauty. Victors in the Olympian games were crowned with wreaths of its leaves. The myrtle of Peru and Chile has red berries and smaller leaves. The berries have a pleasant flavor and are eaten. The periwinkle, which is a very common running plant in the United States, is often improperly called myrtle.

Mytile'ne. See LESBOS.

Myxomycetes (*miks-o-ma-sē'tēz*), organisms commonly called "slime moulds," which do not seem to be related to any group of plants, and have raised the question as to whether they are to be regarded as plants or animals. The ordinary body is a mass of naked protoplasm, called the "plasmodium," suggesting the term slime. This body slips along like a gigantic amœba. Slime-moulds are common in forests, upon black soil, fallen leaves, decaying logs, etc., and are slimy yellow or orange masses, ranging from the size of a pin-head to as large as a man's hand. In certain conditions these slimy bodies come to rest and organize elaborate and often very beautiful spore-cases. As is often remarked, the body of these organisms is animal-like, while the sporangia are plant-like.

N

Nachtigal (*näk'tē-gäl'*), **Gustav,** a German explorer and traveler, was born at Eichstedt, Feb. 23, 1834, studied medicine and served as surgeon in the army until 1863, when he went to Algeria and Tunis for his health. In 1868, he was selected to carry presents from the king of Prussia to the sultan of Bornu, and starting from Tripoli in 1869 he went through Fezzan, Tibesti, Wadai, Darfur, Kordofan, and from Cairo home, arriving Nov. 22, 1874. Being one of the first Europeans to visit these states, it placed him among the foremost of modern travelers. His collection of information is recorded in the three volumes of *Sahara und Sudan.* In 1884, he was sent to annex Togoland, Kameruns, and Lüderitzland for Germany, and died on his return journey, off Cape Palmas, Liberia, on April 19, 1885. See Dorothea Berlin's *Erinnerungen au Nachtigal.*

Nadir (*nā'dēr*), an Arabic word used by astronomers to denote the point just opposite the zenith. The *zenith* being the point immediately over head, the *nadir* might be defined as the point immediately under foot. A plumb bob suspended by a string always points to the nadir and to the zenith, at the same time.

Na'dir Shah, of Persia, belonged to a Turkish tribe and was born at Khorasan in 1688. After entering the service of the governor, he was degraded for some offense and entered a life of lawlessness, becoming the head of a robber band of three thousand. Persia being at that time under the tyrannical rule of an Afghan, Nadir undertook to overthrow him. Persians enlisted under him, and after the fall of the Afghan, and the accession of the rightful heir, Tamasp, to the throne, Nadir was made governor of the provinces of Khorasan, Mazanderan, Seistan, and Kermân. He was sent against and defeated the Turks in 1731, and in 1732 dethroned Tamasp and placed the infant Abbas III. thereon. On the latter's death, in 1736, Nadir was crowned Nadir Shah, and resumed the war against the Turks. He conquered Afghanistan, ravaged the northwest provinces, and took Delhi with booty to the amount of $100,000,000, including the great Koh-i-noor diamond. Then he became suspicious and tyrannical and was assassinated June 20, 1747. See H. Maynard's *Nadir Shah* (Stanhope Essay, 1885.)

Nagasaki (*nä-gä-sä'kē*), a seaport town of Japan, was for two centuries the only harbor in the kingdom open to the world. In 1859, it became one of the five open ports. Its harbor is a beautiful inlet, of over three miles, having, near its head, the island of Deshima, which from 1637 to 1859 was the trading-post and prison-house of the Dutch traders. The great Takashima coal mine, on an island of eight miles seaward, makes Nagasaki an important coaling station. The foreign settlement is on the east side of the harbor. The city has English, American, and Dutch missionary societies, and a community of native Christians. Population in 1898, 107,422.

Nagoya (*nä-goi'ä*), one of the largest and commercially active cities of Japan, the chief town of the province of Owari, lies at the head of the shallow Owari bay, about 30 miles from its port, with which it communicates by means of light-draught steamers. It is one of the largest seats for pottery works, and turns out large quantities of fans and enamels. Nagoya castle, in about 400 acres of grounds, to the north of the city, was built in 1610, and is now the headquarters of the Nagoya military district. A superior court, middle school, girls school, normal school, hospital, prefecture, telegraph and post offices are the buildings of foreign style. Population 244,145.

Nagpur (*näg-pör'*), a city in British India and capital of the Central Provinces. It is a beautiful town, well wooded, having attractive gardens and suburbs, but its high temperature makes it unhealthy. It manufactures fine cloth fabrics and has a good trade in wheat, salt, spices, and European goods. Here it was that 1,350 British under Colonel Scott defeated 18,000 Mahrattas on Nov. 27, 1817. Population 125,000.

Na'hum, the seventh of the minor prophets of the Old Testament. His book is inscribed *The Burden of Nineveh,* the book of the vision of Nahum the Elkoshite. It speaks of the infallibility of divine judgment against the enemies of God and his goodness toward believers, and predicts the destruction of Nineveh. Students have placed the date of this prophecy somewhere between the fall of Thebes (666 B. C.), which is mentioned, and 606 B. C., the date of the destruction of Nineveh. Of his personal history nothing is known. He is supposed to have been a native of Elkosh (modern Elkauseh), upper Galilee, or of Alkôsh, on the left bank of the Tigris, where the grave of the prophet is shown.

Nails. The making of nails by hand has been an established manufacture in Birmingham, England, for 300 years. Before the successful but very gradual introduction of machine-made nails, the men, women, and children, to the number of 60,000, were engaged in the industry in that district. They all worked in small shops or sheds attached to their houses. In 1861, the number employed

was only 20,000, and of these nearly one-half were females. Hand-made nails are being rapidly supplanted by machine-wrought and cut nails. The machine, which is the invention of Mr. G. H. Perkins, of Philadelphia, is fed with heated (to black heat only) strips of metal, having sufficient breadth and thickness for a nail to be made, and with its slicer shears off the "nail blank," which, falling down, is firmly clutched at the neck till a heading die, moving with force enough, strikes against its upper end and forms the head, and the nail is completed.

Nana Sahib (*nä'nä sä'hib*), the name applied to Dundhu Panth, the adopted son of the ex-peshwa of the Mahrattas, when he led the Indian mutiny of 1857. He was born about 1825, and educated as a Hindu nobleman, but was active in stirring up dissatisfaction with English rule, and at the outbreak of the mutiny was proclaimed peshwa, and was directly responsible for the massacres at Cawnpore. After the suppression of the rebellion, he fled to Nepal. The date of his death is unknown, probably 1860.

Nancy (French, *nôn-sē'*), capital of the French department of Muerthe-et-Moselle, lies on the left bank of the river Meurthe, at the foot of the hills. It comprises both the old and new towns, and contains fine squares and beautiful buildings, among them being the Hôtel-de-Ville, the bishop's palace, the theatre, the churches Des Cordeliers and Nôtre Dame de Bonsecours (1738), and St. Epvre. The statue of Stanislaus Leszcynski, king of Poland, who lived here from 1735 to 1766, as the duke of Lorraine, stands in the principal square. The city has manufactories of cotton and woolen goods, artificial flowers, iron, etc., but its greatest industry is embroidery on cambric and muslin. From the 12th century it was the capital of the duchy of Lorraine; it is also the scene of the death of Charles the Bold, 1477, and the birthplace of Callot and Claude Lorraine. The town was occupied by the German army in 1870. Population in 1896, 96,306.

Nanking (*nan-kin'*), capital of the province of Kiangsu, and formerly of China, is situate on the Yangtse river, 130 miles from its mouth. Since the removal of the capital to Peking, the official name has been Keangning-fu. When it was the capital of the Taiping rebels, from 1853 to 1864, the latter destroyed the Porcelain tower, the summer palace, the tomb of the kings, and all the other buildings for which it was famous, and also part of the walls, formerly 20 miles around, and in some places 70 feet high. Since its recapture by the Chinese, in 1864, it has recovered a little. The manufacture of nankeen and satin has been resumed. It was captured by the English in 1842. In 1899, the Chinese government declared Nanking open to foreign trade. Population 225,000.

Nansen, Fridtjof, a Norwegian explorer, was born near Christiana, Norway, Oct. 10, 1861. When 21 years of age he became curator of the zoological department of the museum at Bergen and devoted himself to its improvement. In a number of exploring expeditions he showed such fertility of resource and such physical endurance that he was given larger fields of operation. In 1882, he explored the seas about Greenland. In 1888–89, he crossed the peninsula of Greenland passing over its ice cap from east to west, and returned safe, contrary to the prophecies of his critics. With his thoughts still on the problems of the polar seas he designed a boat in 1892 to withstand the effects of any ice jam; and in this vessel, the *Fram*, he set out from Vardö, Norway, 1893, intending to reach the pole by sailing east until the right opportunity should offer for permitting his boat to be frozen into the ice pack. It was his belief that the pack itself would drift him across the polar sea. His surmises were in part correct. He attained the highest latitude north, but not within many leagues of the pole. He was not heard of again until Aug. 13, 1896, when his safe return was announced. His "farthest north" was about three degrees farther north (86° 14′ N.) than the point attained by the *Alert* in 1876. His published works are *Across Greenland* and *Farthest North*. He is still engaged upon the problem which has so long absorbed his attention. He lectured in the United States after his return from the polar expedition of 1893–96, upon which his chief distinction rests.

FRIDTJOF NANSEN.

Nantes (*nants*, French *nônt*), the ninth largest city of France and capital of the department of Loire-Inférieure, lies on the right bank of the Loire, 35 miles from its mouth. Demolished between 1865 and 1870, Nantes has grown by nature and by art to be one of the handsomest cities in France. Its unfinished cathedral (1434–1852) contains the celebrated monument to the duke and duchess of Brittany. Among its noteworthy buildings are the ducal castle, the occasional residence of Charles XIII. and the place where, on April 13, 1598, Henry IV. signed the famous edict of Nantes; the Church of St. Nicholas, the palace of justice, the theatre, post office, museum, and library of 50,000 volumes. Nantes, the former capital of Brittany, is the scene of the marriage of Anne of Brittany to Louis XII. (1499), the embarkation of the

Young Pretender (1745), and the arrest of the Duchess de Berri (1832). Population (1896), 123,902.

Nan'ticoke, Pa., a borough of Luzerne county, on a branch of the Susquehanna river, and on the Central of New Jersey, the Delaware, Lackawanna, and Western, and the Pennsylvania railroads, twenty miles southwest of Scranton, and eight miles from Wilkesbarre, the county seat. A portion of the town, known as W. Nanticoke, lies across the river in Plymouth township. Its chief industry is the shipping and hauling of coal, being in the anthracite coal-mining regions. Population of Nanticoke, 12,116.

Nantuck'et, an island off the southeast coast of Massachusetts. It is about 15 miles long and much frequented as a summer resort. The town of Nantucket lies on the north shore. It was formerly a great whale-fishing center. Population 3,006.

Naphtali (*naf'tă-lī*), the son of Jacob by Bilhah, Rachel's maid. The name is explained in Genesis xxx. 8. The seat of the tribe was in the eastern half of upper Galilee, in a country sloping to the headwaters of the Jordan and the Sea of Galilee. After the wars with Siserà, in which the tribes took a prominent part (Judg. iv; v. 18), and with Midian (Judg. vii. 23), we hear little of Naphtali. The tribe was depopulated in the first Assyrian captivity by Tiglath-Pileser (2 Kings xv. 29; Isa. ix. 1).

Naphtha (*naf'tha* or *nap'tha*) is derived from a Persian word meaning "to exude" and was originally used to designate the liquid hydrocarbons that oozed from the ground about the Caspian sea. It was also applied to the natural oils, found universally, and to the oil derived from the Boghead mineral in Scotland. But since the discovery of Scotch paraffine and American petroleum the name naphtha has been applied only to the lighter, explosive, and unsafe oils, and, strictly speaking, to the products of distillation from mineral oils, coal tar, india rubber, bones, peat, and wood, the latter being known also as methyl alcohol. Petroleum (American) contains from 15 to 20 per cent. of naphtha, which is separated into gasoline, benzine, and benzoline. The tar derived from the reduction of coal yields from 5 to 20 per cent. The spirit obtained from the destructive distillation of india rubber is called caoutchin. Bone naphtha, or Dippel's animal oil, is obtained by distillation of bones in the manufacture of animal charcoal.

Napier (*nā'pe-er*), Sir **Charles James**, a British general, the conqueror of Sind, and a descendant of Napier of Merchiston, was born Aug. 10, 1782, at London. Being commissioned in his 12th year, he served during the Irish rebellion, and, at the battle (Corunna) in which Sir John Moore died, he was five times wounded and taken prisoner. He returned to England and gave himself to literary work, but in 1811 he went to the Peninsula, where he took part at Coa, Busaco, — where his jaw was broken and eye injured by a shot — Fuentes d'Oñoro, and Badajoz. He also took part in the Anglo-American war of 1812. In 1818, he was made governor of Cephalonia; in 1838, a K.C.B., and in 1841 was sent to India to command the army of Bombay against the Ameers of Sind. Here his most remarkable feat was the destruction of the fortification of Emaun Ghur, 1843, followed by the battle of Meanee (Miani), where, with 2,800 English and Sepoys, he defeated 22,000 Baluchs. After the annexation he was appointed governor of Sind, but differences with the authorities caused him to return to England in 1847. He died near Portsmouth, Aug. 29, 1853. See the biography by his brother, and the short *Life*, by Sir W. Butler.

Na'pier, Sir **William Francis Patrick**, K.C.B., the brother of Sir Charles, was born near Dublin, Dec. 17, 1785. He served in the Peninsular campaign and retired as a lieutenant-general. He also wrote a famous *History of the War in the Peninsula, The Conquest of Scinde*, and the *Life of Sir Charles Napier*. He died at Clapham, London, Feb. 10, 1860. See his *Life and Letters*, edited by Bruce.

Naples (*nā'plz*), until 1860 the capital of the kingdom of Naples, is the largest Italian city and one of the busiest ports, exporting wine, olive oil, chemicals, perfumery, live animals, animal products, hemp, flax, cereals, and importing cereals, metals, cottons, woolens, earthenware, silks, groceries, etc. The well-known proverb, "See Naples and die," became used on account of its attractiveness and delightful climate.

Naples lies upon the base and sides of a hill-range rising from the sea and divided into two unequal parts. The most ancient part of the city, in the eastern crescent, is divided from north to south by its oldest street, Via Toledo (now Via di Roma), and is the most populous district of its size in Europe. Back of the wharf extending to the Castel del Carmine lies the poorest and most densely-peopled quarter. The city is always full of life, the streets crowded and noisy. There are few buildings of any note, the forts and gates, university, royal palace, catacombs, national museum, and law courts only, being worth a visit. It has three large libraries, the national, the university, and the Brancacciana. The university, which was founded in 1224, has a faculty of 81 professors, and a student body of 5,465. Population (1899) 544,057.

Na'ples, a former kingdom in Southern Italy, owed its creation to Greek colonists, the two settlements, Palæopolis and Neapolis, long existing as one community, Parthenope. After the subjugation by Rome only Neapolis remained and became Rome's ally. After resisting Pyrrhus and Hannibal, it fell, by

treachery, into the control of Sulla's friends, who murdered its people (82 B. C). Under the empire it became a famous residence place on account of its poets and its climate. After the fall of Rome, it sided with the Goths, but was taken by Belisarius (536), and six years after by Totila. Soon after the Byzantine emperors acquired it through Narses and it was made the head of a duchy. As such it revolted and remained independent until conquered by the Normans in the 11th century. In 1266, the popes gave the sovereignty of Naples to Charles of Anjou, but during the reign of Robert I. the predominance of the papal party, the ravages of the Germans, the depravity of Joanna, Robert's heiress, and the unsuccessful attempts to recover Sicily, were the only important events that marked the Angevin rule, which ended with Joanna II. in 1435. Then succeeded the Aragon rule. Between 1494 and 1504, France and Spain fought for the possession of Naples, but it was united with Sicily, forming the Two Sicilies, and was governed by Spanish viceroys down to 1707. In that year Austria wrested Naples from Spain only to give it, in 1735, to Don Carlos, who founded the Bourbon rule. In 1789, it was invaded by the French troops and again, in 1806, when Napoleon proclaimed his brother Joseph king. In 1808, the crown was given to Joachim Murat, and on his defeat and execution in 1815, the Bourbon monarch, Ferdinand IV., was restored. The revolutions of 1821 and 1848 led to the overthrow of the Bourbon government by Garibaldi, and to the incorporation of Sardinia and Naples with the kingdom of Italy in 1861. Naples (Napoli) is to-day a province of Italy, with an area of 350 square miles, and a population (1900) of 1,197,743. See *History of the Kingdom of Naples*, by Colletta, translated by S. Horner.

Napo'leon I., the first emperor of France, was born at Ajaccio, Corsica, Aug. 15, 1769, and ten years later entered the royal military school at Brienne le Chateau, from which he was transferred to the military school at Paris. From here he graduated as second lieutenant, and began the ambitious career that characterized his after-life by entering the first revolution and attempting to seize the Corsican cities for France, but failed. As lieutenant-colonel in the second revolution, he attempted to capture Sardinia, but failing, he fled to France with his entire family, and looked here for glory and renown. He joined the army under Carteaux, and acted as chief of battalion against the Marseillais, and was promoted to general of brigade for planning and causing the fall of Toulon. He was given command of the army of Italy in February, 1796, and two days before entering upon the campaign he married Josephine, the widow of General Beauharnais. In Italy, he began the course which marked him as a man of determination, force, and quick action, and by wonderful strategies defeated the allied forces of Italy and Austria. In this campaign he lost not even a single engagement, but moved so rapidly and decisively, that with an army of about half the number of the allies, he won repeated victories and levied large contributions from defeated towns. After his victory in Italy, he decided to move on Vienna, but Austria made overtures for peace, ceding to France Lombardy, Belgium, and the Ionian islands at the conclusion of the treaty.

On his return to France, the secretary, fearing that his ambition would lead him to foment a revolution for personal ends, placed him in command of the army of England, with which he determined to conquer Egypt and found an eastern empire. He reorganized the army and embarked from Toulon in May, 1798. Taking Malta on the way, he arrived at Alexandria and marched on Cairo, which he entered on July 24. His fleet was destroyed in the Nile by Nelson, and he turned his attention to Syria and formed a brilliant idea of overthrowing Turkey and entering Europe through Asia Minor and Constantinople. However, hearing that the armies at home were meeting with misfortune, he embarked for France secretly, leaving the army in command of Kléber. He arrived at Paris just in time to fill the want of the leaders, who were looking for a man to place at the head of the new movement. The revolution of Nov. 10, 1799, gave rise to the formation of a new constitution, which Napoleon assisted in framing, and by it the provisional government was vested in three consuls, of which Napoleon was elected president. He thus became practically sole ruler of France. Then, in 1800, after failing to conclude peace with Austria and England, he determined to stake all on the chance of a campaign, and entered Italy desperate for victory. He was saved from defeat by Melas, on the plain of Marengo, by the timely arrival of Desaix's army, and, upon Moreau's victory at Hohenlinden, he made peace with Germany and England, gaining all of Italy.

He then turned his attention to the formation of the permanent civil institutions, restoring the church, establishing the judicial system, the codes, the system of local government, the university, bank of France, and the Legion of Honor. This done and peace thoroughly established, he was fired by the ambition to become the ruler of the world, and after being elected first consul for life, he ruptured the peace with England by proceeding upon Holland, Genoa, and Piedmont, demanding that England should suppress all papers criticising his actions, and drive all French refugees from its shores. He entered Germany, seized Hanover, and assumed the crown. He then roused the Royalists by executing the Duc D'Enghien, and winning the Republicans over to his way of thinking, he chose the title of emperor, which was confirmed by the senate, May 18, 1804. The

advance upon England was met by a coalition of the powers of England, Austria, Prussia, and Russia; but Napoleon, nothing daunted, marched upon Austria and defeated her at Austerlitz, in December, 1805, breaking up the coalition. But Prussia gathered her armies in August, 1806, and was joined by Russia. They were defeated at Jena and Auerstädt on October 14, and Berlin was taken October 27. Then the Russians were defeated at Friedland in June, 1807, and by the ensuing peace Prussia lost half her territory. Napoleon's great aim was the humiliation of England, and to this end he caused all continental ports to be closed against her; but England retaliated by defeating his army in Spain and Portugal. In Germany, also, revolt was rife, Austria leading the way, and after several attempts to cross the Danube, Napoleon defeated them at Wagram, July 5, 1809, and received a large part of their territory as indemnity. He, however, greatly offended the czar by giving Galicia to Poland. His wife bearing him no children, he divorced her and married Maria Louisa of Austria, by whom he had a son.

His persistency against England brought him into conflict with Russia, and Napoleon determined to invade that country. So, with 600,000 men, he crossed the continent, being greeted by the king of Prussia and emperor of Austria, and entered Russian soil on June 24, 1812. He defeated the Russians at Borodino and entered Moscow on Sept. 14, on which a great fire broke out and lasted until the 20th. He resolved upon a retreat on Oct. 18, and upon reaching the frontier had but 100,000 men left. He returned to France to raise new armies, while Russia joined with Prussia and Saxony to withstand his attack. They met, in a victory for Napoleon, May 2, 1813, at Lutzen, and Austria was appointed a mediating power to effect peace or declare war in case of refusal. Napoleon paid no attention to the ultimatum, so on Aug. 11, he found himself at war, with 400,000 men, with all the powers of Europe. He was terribly defeated at Leipsic between Oct. 14 and 19, and retired to Mainz with only 70,000 men. The allied armies separated and, after the defeat of Blücher four times in four days by Napoleon, they joined forces and marched upon Paris and took it March 30, 1814. Wellington then came from Portugal and also entered French soil. Napoleon offered to abdicate in favor of his son, but this was refused, and he retired unconditionally, on April 11, 1814, being given the sovereignty of the island of Elba.

The accession of the Bourbons was unpopular and Napoleon thought he could save France from ruin, so on March 20, 1815, he again entered Paris at the head of the army. He had, however, become old and ill, and while his conceptions and plans were as brilliant as ever, the execution of the campaign of Waterloo failed. The English under Wellington, and the Prussians under Blücher, were against him. On the 16th of June he defeated Blücher at Ligny, but failed to follow up the victory, so that when he turned against Wellington, the Prussians, unknown to him, were in the rear, and this caused the defeat of Waterloo on June 18. He fled to Paris, and finally abdicated, June 22. Finding escape impossible he surrendered to Captain Maitland, of the *Bellerophon*, on July 15, and was sent a prisoner to St. Helena, where he arrived Oct. 15, 1815, and died of cancer of the stomach on May 5, 1821. See Seeley's *Short Life; Memoirs of Napoleon Bonaparte*, by Bourrienne, and the *Correspondence of Napoleon I.*

Napoleon III. or **Charles Louis Napoleon Bonaparte**, the second French emperor, was born at Paris on April 20, 1808. His father was king of Holland and brother of the first emperor and his mother was the stepdaughter of Napoleon I. He was educated by his mother in exile in Switzerland and at the gymnasium at Augsburg, but until 1836, during his life in Switzerland, he was, essentially, a student and writer. Nevertheless, the prestige of the institutions of Napoleon I. cast some reflected light on Charles Louis, who looked with longing eyes toward the throne of France, then occupied by Louis Philippe. Indeed, he went so far in 1836 as to appear among the military at Strasburg and endeavor to win them over to his side, but failed, and was taken and brought to the United States without trial. He, however, again returned to Switzerland, of which government France demanded his expulsion, but it was refused. To avert trouble he went to England and in 1840 made his second attempt to gain the throne by landing at Boulogne, but was this time taken prisoner and sentenced to imprisonment for life at the fortress of Ham. Here he remained, writing many books, and editing the French Encyclopedia, *Dictionaire de la Conversation*, until he made his escape to Belgium, May 25, 1846. Immediately upon the success of the workingmen in the revolution of 1848, he returned to France and was elected to the constituent assembly from Paris and three other districts, but resigned his seat two days after taking it and left France. In September, 1848, he was recalled by his election from five districts and immediately began the canvass for the election to the presidency, which he received by an overwhelming vote. For a while he lived up to his oath of allegiance to the republic taken on Dec. 20, but only as a cloak to place the military under control of his friends and lay plans for the resumption of the monarchy. On Dec. 2, 1851, by force of arms, he routed the national assembly and in that same month he was re-elected for ten years, only to assume the imperial title within a year. The empire being now established, he broke up the political parties,

courted the clergy, and adopted a brilliant foreign policy. This led to the Crimean war and the difficulty with Austria in Lombardy. While in these operations he enjoyed the support of Great Britain, his relations to Prussia were affected by jealousies, which finally led to the Franco-Prussian war, which proved the end of Napoleon III's power. He surrendered himself in September, 1870, and was held a prisoner at Wilhelmshöhe, near Cassel, until the declaration of peace, after which he joined the empress at Chiselhurst, near London, where, after writing a *History of Julius Cæsar*, he died on Jan. 9, 1873. See Blanchard Jerrold's *Life of Napoleon III.; Napoleon the Little*, by Hugo; *Essay on Napoleon*, by Channing.

Narcis'sus, according to a Greek fable, was the son of the river god Cephissus and the nymph Liriope, in Bœotia. The boy was very beautiful and more than vain of his beauty. As a punishment, Nemesis made him fall in love with himself, on seeing the reflection of his face in a stream or fountain, and he died of this lovesickness. From the place where he died sprang the flower which bears his name.

Narcot'ics. See POISONS.

Narragan'sett Bay, in Rhode Island, is about 28 miles in length, reaching north from the Atlantic into the state, and from 3 to 12 miles wide. It divides Rhode Island into two unequal parts, of which the western part is much the larger. It contains several islands, of which Aquidneck, Canonicut, and Prudence are the largest. The rivers Pawtuxet and Pawtucket empty into it.

Narragan'setts, a tribe of Indians belonging to the great Algonquin family. When New England was settled, they lived in what is now Rhode Island. They then numbered 7,000 or 8,000, but were more civilized and less warlike than other of the New England tribes. In 1621, their sachem, Canonicus, sent a bundle of arrows tied with snakeskin to the Plymouth colony, signifying hostility. Governor Bradford changed their purpose by promptly returning the skin filled with bullets and powder. Roger Williams went to them when exiled from Massachusetts, and had influence in their councils, persuading them to peace in 1636, when they were again hostile to the whites. In King Philip's war, more than thirty years afterward, they were believed to be aiding the enemy, and the English, with the Mohegans and Pequots, burned their fort. They retaliated and a large force was sent to punish the hostile Narragansetts, and they were nearly exterminated. The few who remained became civilized, lived in peace with the whites, and lost their native language. There are now only about 150 Narragansetts.

Nar'ses, statesman and general, one of the last supports of the old Roman empire, was born in Persian Armenia about 478 A. D. From a low position he rose to be keeper of the privy purse to Emperor Justinian. Some years later, he was given sole command in Italy. His conduct of this campaign was very masterly; having no transports, he marched his army around the shores of the Adriatic, encountered the Ostragoths at Taginae and defeated them, slaying their king, Totila, and, after further successes and taking possession of Rome, Narses completely destroyed the Gothic power in the peninsula. He was then made prefect of Italy and held court at Ravenna until the death of Justinian, when, being accused of avarice and extortion by the people, he was removed by Justin, 567. Narses died at Rome about 573 A. D. See Goth's *Justinian*, and Hodgkin's *Italy and Her Invaders*.

Nash'ua, a manufacturing town of New Hampshire, in Hillsboro county, at the junction of the Merrimac and Nashua rivers, and about 40 miles from Boston. By means of a three-mile canal, the falls of the Nashua river furnish power to many cotton factories, paper, carpet, and iron mills. Population 23,898.

Nash'ville, the capital of Tennessee, lies mainly on the left bank of the Cumberland river, about 200 miles from the Ohio, which is here crossed by a suspension and a railway drawbridge. It is a well-built city, containing the new capitol, a penitentiary, and a large insane asylum. Besides an excellent school system, it is the seat of Nashville university, Vanderbilt university, Central Tennessee college, Fisk university, and Roger Williams university (the last three for colored students), and the State Normal school. It has a good trade in cotton, tobacco, flour, oil, paper, timber, leather, iron, and spirits. The town was founded in 1780 and became the capital in 1843. General Thomas defeated the Confederates under Hood here, in December, 1864. Population 80,865.

Nasmyth (*nā'smith*), **James,** a British engineer, and the inventor of the steam hammer, was born at Edinburgh, Aug. 19, 1808, and early showed an inclination for mechanics. At seventeen, he built a small working engine for crushing, made five models of a condensing engine, and a road locomotive. In 1839, he had to turn out a large wrought-iron paddle-shaft, and invented the steam hammer to do the work, but it was not perfected until 1842. He patented his invention, and it was adopted by the government in 1843. In 1856, he retired and died at London, May 7, 1890. See *Life*, by Smiles.

Nast, Thomas, an American caricaturist, was born in 1840 at Landau, Bavaria, and came to this country in 1846. At the age of fourteen he studied drawing for six months with an instructor, and a year later was employed as draughtsman on *Frank Leslie's*

Illustrated Newspaper. Five years later, as special artist of this periodical, he was sent to England, and from there went to Italy, sketching the history made by Garibaldi, for the illustrated papers of New York, Paris, and London. In 1861, he returned to New York and began his war sketches and political cartoons for *Harper's Weekly*, which were immensely popular. Later he has appeared with success on the lecture platform, and has illustrated several books, among them those of Petroleum V. Nasby, and *Nast's Illustrated Almanac*.

Natal (*nă-tăl'*), a British colony on the southeast coast of Africa, was discovered by Vasco da Gama on Christmas day, 1497, and in 1800 was peopled by ninety-four separate tribes of natives. Tyaka, a chief of the Amazulu tribe, ruled the country from 1805 to 1828, when he was killed and his brother, Dingaan, placed on the throne by a political faction. Then the Boers, who had left Cape Colony to escape English rule, began a series of struggles with the natives, and in 1838, when a commission of Boers was murdered by Dingaan, a large body entered Natal to avenge the murder. The Dingaan faction was at that time opposed by the followers of his brother Umpande, and with these the Boers united, attacking Dingaan and killing him. Umpande then succeeded, recognizing the Boers as lords of the soil of Natal. In December, 1838, Sir George Napier, governor of Cape Colony, was sent to take possession of the territory, but his Highlanders were compelled to go to Cape Kaffir on account of disturbances there, whereupon the Boers hoisted the flag of the republic of Natalia. Later two English men-of-war forced a landing at Durban, and after a short struggle drove the Boers back to their capital. Peace negotiations were then concluded, and the larger portion became subjects of the British crown. But some crossed the mountains and entered what is now the Transvaal.

The colony was formally annexed to the British dominions in 1843, and in 1844 became a part of the Cape of Good Hope. In 1856, Natal was declared to be a separate colony, and was given a sort of independent government, and before 1860 a great part of its soil was held by immigrants from England. In 1875, there was great dissatisfaction on account of the English rule, and Sir Garnet (now Lord) Wolseley was sent to adjust matters. He was succeeded as governor by Sir Henry Bulwer. During his administration the fear of the strength of the neighboring Zulus, under Cetewayo, became so great that Sir Bartle Frere, high commissioner for South Africa, against the protests of colonists and the governor, sent a message which precipitated the Zulu war, from the results of which Natal was long in recovering. The charter of the colony now in force was granted in 1893, and in 1897 the province of Zululand was annexed to Natal. The legislative authority resides in the crown, a legislative council, and a legislative assembly—the crown being represented by a governor, who appoints the ministry, and, with their advice, the members of the legislative council. The capital is Pietermaritzburg, situated inland about 50 miles northwest of Durban, the chief and almost only seaport. The colony (including Zululand) has an area of 35,000 square miles, with a seaboard of about 400 miles. In 1898, its population was 902,365, of which 787,574 were Kaffirs, the remainder being Europeans or Indians. The population of the capital is about 25,000, and of Durban about 40,000. Its products include sugar, maize, wheat, oats and other cereals and green crops—the chief exports being wool, hides and skins, coal, gold, bark, sugar, and Angora hair. The coal fields of the colony are known to be extensive, and are now in direct communication with the seaport. Portuguese East Africa, and the Transvaal colony (separated by the Drakensberg mountains) border Natal on the north, Orange River Colony and Basutoland on the west, and Cape Colony on the southwest. The colony in the main is fertile, and is possessed of a salubrious climate. Winter in South Africa begins in April and ends in September.

As the result of the Boer war between Britain and the Transvaal and the late Orange Free State, Natal, in October, 1899, became at once the theatre of strife. See BOER WAR.

Nat'chez, Miss., an old-settled city, capital of Adams county, on the Mississippi river, in the rich cotton belt of the state, 90 miles southwest of Jackson, and 280 northwest of New Orleans. It is connected by a bridge across the river with Vidalia, La., and is served by the New Orleans and Northwest, and by the Yazoo and Mississippi Valley, railroads. The town mainly lies on the banks of the river; while the public buildings and residences are situated chiefly on a bluff above. It handles cotton largely, and has a number of factories, mills, steam-ginneries, etc. Population 12,210.

Na'tional Debt is the debt of a nation or government contracted by their legislative representatives. In early times these were comparatively small, because the government, as well as the individual, had to give security for the indebtedness; but since the commencement of the present system of banking and the ability of governments to issue interest-bearing evidences of indebtedness in the shape of bonds, the national debts have become in many cases, as for instance, that of France, quite enormous. Regarding the origin of these vast obligations, the most prolific cause is the wars in which the different nations have from time to time engaged; thus, the Civil war added about $2,500,000,000 to the national debt of the United States. Of late, however, the governments have borrowed

money for different public purposes, such as building railroads, telegraph lines, and equipping armies and navies. The present system of securing the national debt is by the issue of bonds, bearing a stated rate of interest, payable quarterly, and maturing or becoming due at a certain date. The debt of the United States is in part secured in this way and in part by the issue by the government of greenbacks or paper currency, actually nothing more or less than promissory notes, due upon demand, at presentation at the United States treasury. The method adopted in the United States for the payment of the debt is by the taxation of spirits, whiskey, tobacco, and butterine, and charging certain amounts for the traffic in these articles, and by the levy of a tax or tariff on articles imported into the country. The greatest amount ever owed by this government was $2,773,236,173 in 1866, directly after the Civil war, but this was reduced to $798,137,603.28 in 1892. The debt (Dec. 31, 1900) of the United States was a trifle over a thousand million dollars — that is, the interest-bearing debt; the debt bearing no interest, represented chiefly by United States bank notes, amounted at the same date to 385 million dollars. Besides this national indebtedness, some 750 millions represents treasury notes and certificates; but this sum is offset by cash in the treasury. The indebtedness of the chief nations in 1900 was: Great Britain (funded and unfunded debt), £3,100,000,000; France, total debt, including interest and annuities, £6,260,000,000; Germany, total debt (bearing interest at 3% and 3½%), less war treasury fund, $555,000,000; Russia, total debt, including that incurred for state railroads, $3,575,000,000; Italy, $2,580,000,000; Austria-Hungary, consolidated and floating debt, $1,250,000,000; China, outstanding foreign debt (raised chiefly to meet expenses connected with the war with Japan), $270,000,000.

National (*nash'un-al*) **Park.** See YOSEMITE.

Nat'ural Bridge, The, an arch of limestone which spans a small river in Virginia, one of the features of the landscape in the far-famed Shenandoah valley. It stands among cascades and caverns and deep pine woods, a mighty arch of a single stone. It is 215½ feet in height, 100 feet wide, and has a span of 80 feet. It occurs west of the Blue Ridge, and 14 miles from Lexington, Va.

Nat'ural Gas, the name applied to combustible gas which escapes from beneath the soil in such quantities that it may be used for fuel or illuminating purposes. In its natural state, the gas occurs in porous sedimentary rocks, and when proper openings are made, it rises to the surface. Wells are drilled for gas, just as for oil or water. Natural gas is the product of decay or distillation of organic matter buried in sand, mud, etc. By its burial, the organic matter is shut off from contact with the air, and hence the gases arising from its deposition and distillation are not completely oxidized. Organic matter is now being imbedded in sands and muds which are in process of deposition on lake and sea bottoms. Under proper conditions this might ultimately give rise to gas. Natural gas is really a mixture of several gases in variable proportions; among them marsh gas (CH_4) and hydrogen are usually most abundant.

Natural gas is widely distributed. It is extensively utilized in Indiana, Pennsylvania, Ohio, West Virginia, New York, and California; and to a limited, but still important extent, in Kansas and Kentucky; and to a slight extent in Utah, Colorado, Illinois, Missouri, and Texas. The commercial value of the gas consumed in the United States in 1898 was more than $15,000,000. The flow of gas from a well is usually of short duration. It may last for a few months or even years, but not indefinitely. The popular notion that the withdrawal of gas from beneath the surface leads to earthquakes, etc., is wholly without foundation. The gas occurs in the pores of rock, and its escape does not make the rock less firm or substantial. Gas occurs in rock formations of various ages. Some of it comes from rocks as old as the Ordovician (see GEOLOGY), and some of it from formations as young as the Tertiary, or even Pleistocene. Natural gas and petroleum are probably associated in origin, as they often are in their distribution.

Nat'uraliza'tion, the process by which a person born in another country becomes possessed of the privileges and is placed under the obligations of a citizen of the country in which he resides. It involves the renunciation of allegiance to one country and the adoption of the other. It was not until 1870 that Great Britain recognized such a renunciation by any of its subjects, and before that time would charge with treason any person having so done, if he bore arms against Britain; but in that year a treaty was made by which Englishmen who had been naturalized in this country, were treated as citizens of the United States and vice versa. The conditions upon which one can become naturalized differ materially in various countries. In the United States, a foreigner must make oath of his intention to become a citizen. If at this time he has resided three years in the United States, he receives what are known as his "first papers." Then, after the lapse of two years, upon a sworn substantiation of his good morals, a five years' residence and a renunciation of all allegiance to any and all foreign monarchs or potentates and all titles of nobility, before any one of the superior, district, or circuit courts, he becomes a citizen of the United States. In Great Britain, five years' residence or service under the crown entitles a foreigner to a certificate of naturalization, procurable from one of the principal

secretaries of state. The British colonies make their own rules for becoming a citizen, applicable, however, to only the colony in which they are made. In France, a foreigner, after having obtained permission to reside, may receive a certificate of declaration of intention after three years' residence, and by the French naturalization act of 1889, may become naturalized after ten years' residence without any preliminaries. In Germany, an applicant must show that the laws of his country allow him to renounce it, that he is residing in Germany, leading a respectable life, and has a means of livelihood; then the higher administrative power issues his papers. In all countries a married woman is considered as subject to the country in which her husband is naturalized, and a father's naturalization carries with it that of his minor children. See *Nationality*, by Chief-Justice Cockburn.

Nau'gatuck, Conn., a town in New Haven county, on the Naugatuck river, 5 miles south of Waterbury, and 15 miles northwest of New Haven. It is served by the New York, New Haven, and Hartford railroads. Its manufactories receive their water-power largely from the river. These include rubber and woolen goods factories, buttons, boots and shoes, cutlery establishments, and agricultural implement works, etc. Population 10,541.

Nautilus (*naw'ti-lŭs*), a mollusk having a chambered shell and belonging to the class Cephalopoda. It is the sole living representative of one order of that class, possessing four gills while the other cephalopods have only two. Its shell is not uncommon on the shores of warm seas, but the animal is not often found inhabiting the shell. It creeps about the bottom, and the floating shell is the result of storms. It is called both pearly nautilus and chambered nautilus. The former name comes from the pearly appearance of the innermost layer of the shell, and the latter, from the circumstance that the spiral shell is divided into a set of chambers. The animal lives in the outermost one. When very young it lives in a small shell shaped like a horn. As it grows, it draws the body forward and secretes a pearly partition just back of it, and adds to the margin of the opening of the shell; this is repeated, and a set of chambers results. The animal has a plump body connected with the apex of the shell by a sort of cord, which passes through the center of each partition wall. There are large eyes. The head is surrounded by a number of arms or tentacles, which do not possess suckers like the squid or devilfish, to which the nautilus is related. The paper nautilus, or argonaut, is sometimes confused with the true nautilus. It, however, belongs to another division of the cephalopods having only two gills. The shell of this animal is secreted by the female only, as a case or cradle for the eggs, and is not a shell to protect the animal. In geological times there were huge chambered shells inhabited by animals like the nautilus. These shells were straight instead of being coiled and are well known under the name orthoceratites. See Woodward's *Manual of the Mollusca* (fourth ed. 1880) and Holmes' poem, *The Chambered Nautilus*.

NAUTILUS SHOWN IN SECTION.

Navajo (*năv'vă-hō*) **Indians**, a tribe of American Indians belonging to the Athabascan or Tinney stock. They call themselves Yutahenne. They occupy a fine reservation in Arizona and New Mexico, and are in a good degree civilized. They carry on farming, though their utensils are mostly hoes and primitive implements, such as sharp sticks. Their leading crops are corn, beans, melons, pumpkins, and wheat, and they have orchards of peaches and apricots. Their reserve includes 5,468,160 acres of land, and about 15,000 of this is under cultivation. They have 40,000 horses, 500 mules, 1,200 neat cattle, and 1,100,000 sheep and goats, besides many burros and asses. They number about 17,000. While not given to fighting, they have much spirit in defending their rights. There is a school on their reservation, but the Indians do not compel their children to attend it. The houses are rude booths or huts, built of sticks, sods, or bushes. As they never enter a house where one has died, when a death occurs, the corpse is buried by pulling out the prop sticks and letting the sods and sticks fall on it. The Navajos are strong and well built, and are expert horsemen and herders.

Na'val Acad'emy of the United States, The, a school for the training of naval cadets under the supervision and control of the government, was founded by federal authority in 1845, and opened for the reception of students in October of that year. It is located at Annapolis, Md., on the Severn river, and occupies the site of old Fort Severn. Previous to this date there had been a school for the training of midshipmen in connection with the Naval asylum at Philadelphia, Pa. When the academy was placed at Annapolis, James K. Polk was President and George Bancroft was secretary of the navy. Commander Franklin Buchanan was the first superintendent. The institution was reorganized in 1850, and again in 1851, important changes taking place at each of these dates. The grounds with the buildings occupy a site of fifty acres, while outside the walls 100 acres additional belong to the park. Cadets are appointed by members of the house of representatives, each member being allowed one cadet graduate every six years. By appointment of the President one

cadet is allowed the District of Columbia, and ten from the country at large. Candidates are required to pass an examination (after appointment) as to their physical soundness, their knowledge of spelling, grammar, geography, history of the United States, arithmetic, and algebra as far as equations of the first degree. They must be not less than fifteen years of age and not over twenty. If admitted they must make a deposit of $200 to cover the cost of personal outfit; but their expenses of travel from their homes to Annapolis are refunded to them, and they receive $500 a year, their subsistence, clothing, and certain other expenses being, however, required of them. The course has been changed several times, but, as it now stands, all cadets must pass four years at the academy and two years at sea. During the first three years of their residence at the academy cadets are instructed in English studies, history, French, Spanish, or German, algebra, geometry, trigonometry, astronomy, physics, chemistry, mechanical drawing, and navigation. The studies of the fourth year are varied according to the special line of duty to which the cadet devotes himself, such as naval construction, gunnery, infantry tactics, international law, etc. The number of cadets at the academy varies from 225 to 265, the average graduating class being about 50.

Na'val Observ'atory of the United States, The, an institution of the federal government, is located at Georgetown, District of Columbia, under the superintendence of the bureau of navigation. It was established in 1842, and then called the Depot for Naval Charts and Instruments. The *Nautical Almanac*, issued yearly, is compiled at this place. The present equipment of this observatory is probably surpassed by no other in the world for the performance of the important functions intrusted to it.

Navarino (*nă-vă-rē'nō*) (officially **Pylos**), is a town of 2,000 inhabitants on the southwest coast of Morea, in Greece, and the best harbor in Greece. In 425 B. C., the great battle between the Athenians, under Cleon, and the Spartans, in which the Spartans were defeated, occurred in the bay of Navarino; and in October 20, 1827, the combined British, French, and Russian fleets completely annihilated the Turkish and Egyptian navies at the same place.

Navarro (*nă-vär'rō*), **Mary Antoinette (Anderson)**, an American actress, was born at Sacramento, Cal., July 28, 1859. She was, as a child, educated in a convent, but began studying for the stage when only thirteen years of age, and made her appearance in Louisville, Ky., her home at the time, as "Juliet," in *Romeo and Juliet*, when in her seventeenth year. The next year she began playing in New York, and was from the first received with great favor. Three years later she visited Europe for study and recreation. In 1883, she made her début in London, and was received with enthusiasm from the first. While in London she produced the *Winter's Tale*, which ran through an entire season without change. Transferring play, scenery, and assistants to New York, she brought out the same play there with equal success. She was married at Hampstead, England, June 18, 1890, to Antonio F. de Navarro, son of a wealthy Mexican resident of New York city, and she then withdrew from the stage. Mrs. Navarro published, in 1896, a book of reminiscences entitled *A Few Memories*, which exhibited no little ability and which sold largely.

Naviga'tion is the art of conducting a ship at sea from port to port. There are two methods of determining the situation of a ship at sea. One method consists in finding the latitude and longitude by astronomical observations, the other method consists in noting the ship's direction and the distance traveled each day, and computing by trigonometry the position of the ship. In the latter method the two instruments used are the mariner's compass to determine the direction, and the log line to determine the rate of travel. Winds and currents and variations of the compass needle render this method untrustworthy. The most accurate method of determining the position of a vessel is by astronomical observations. Every ship is provided with at least one accurate chronometer. Then, by noting accurately the time when the sun reaches its highest altitude, the true noon is found, and from difference in time as noted from the chronometer, the longitude can be calculated. Similarly, the latitude may be calculated by observation with the sextant of the sun's altitude in the heavens at noon. When the sun is obscured at noon other astronomical methods are resorted to, such as observations at other hours and on other heavenly bodies. No one method is ever relied on solely, but every observation possible is made to check up others. Currents and temperatures of the sea are made, depths are noted by the lead, and when land is approached, lighthouses and light-ships are carefully watched for.

Na'vy. The navy of any country is its fighting force on the sea, and bears the same relation thereto as does the army as a land-force. The ancient method of naval warfare was in great part the practice of driving a beaked vessel against another with great force. This survives to the present day in the use of *rams*. The ancient boats were propelled with force and precision by oars, arranged in one, two, or three tiers, and manned by either standing or sitting sailors. A three-banked vessel was called a trireme. The Persians, Carthaginians, Phœnicians, and Greeks are known to have had such fleets as early as the 7th century B. C. The first sea fight recorded is the one between the

Corinthians and their colonists of Corcyra, in 664 B. C., and the first naval battle of note was that of Salamis, when the Greeks, under Themistocles, with 336 triremes, defeated the Persians with 1,200 triremes and 3,000 smaller vessels. Grecian power over the sea lasted until the lowering of the Athenian standard in the Syracusan war, in 414 B. C., and Carthage became queen of the seas until in turn conquered by Rome. Then the northern peoples and Moors introduced swift-sailing vessels, which led to the building of such fleets by Venice, Genoa, Pisa, Aragon, the Knights of Malta, and Turkey on the Mediterranean, and by England and France on the seaboard. Toward the 16th century, the Turkish fleet was the most powerful on the Mediterranean, and the Christian powers then formed a combination for defense. The battle of Lepanto, in which the Turkish power was temporarily broken, was fought in 1571. The united fleets comprised 206 vessels, and the Turkish 240, of which 224 were either sunk or captured, while 30,000 Turks were killed and 15,000 Christian galley slaves liberated. Toward the close of the 16th and 17th centuries, naval power was divided between the English, French, Spanish, and Dutch.

The modern navy dates from the 16th century, when, in 1588, the English fleet destroyed the Spanish Armada, and by slow steps in conquering the French and Dutch, became the foremost maritime power of the world. The first naval ship to be protected by iron was launched at Toulon in 1859 and named *La Gloire*. From this were patterned the subsequent armor-clad vessels, with improvements from time to time. The construction of the American navy dates from the war of independence, and in 1812 and 1814 proved a worthy foe of England on the seas. Thereafter it was in a measure neglected until the Civil war, when the construction of the armored *Monitor* changed the type of the warships of the future. Since 1887, a new navy has been built. In place of the old wooden vessels it is composed of powerful steel steamers, capable of high speed, and mounted with batteries of powerful modern guns. The expenditure on the naval establishment of the United States for the fiscal year 1901 was sixty million dollars. This large sum includes, besides disbursements in the maintenance of the fleet and the national defense, expenditures for the construction and armament of new vessels of such a formidable type as the great battleships, the new *Maine*, *Oregon*, *Illinois*, *Kentucky*, *Iowa*, *Kearsarge*; the first and second-class cruisers, such as the *Brooklyn*, *New York*, *Baltimore*, *California;* the double turret monitors and harbor-defense vessels, of which the *Puritan*, *Arkansas*, *Connecticut*, are fine examples; besides armored rams, gunboats, and torpedo-boat destroyers. The effective navy of the United States, in 1901, consisted of 10 battleships, besides six under construction, 8 coast-defense ships, 21 cruisers, 20 gunboats, 26 torpedo boats, and 10 torpedo-boat destroyers, in addition to a number, in the different classes, in the shipyards in various stages of construction. The more formidable vessels of the fleet have a displacement of 12,500 tons, engines of 16,000 to 20,000 horse-power, and a speed of 18 knots. The fleet comprises the battleships, which are practically floating forts, heavily armored, but capable of high speed; the cruisers, less heavily armored, but of greater speed; the double-turreted monitors for harbor defense, besides the large number of single-turreted monitors, gunboats, and torpedo-boats. The destructive power of modern ships and armament, when fought by brave and skillful sailors, was shown in the annihilation of the Spanish fleets in Manila bay and off Santiago de Cuba, by the Americans under Commodore Dewey and Admiral Sampson. Congress has authorized the construction of additional battleships, cruisers, and torpedo-boats, so that the strength of the American navy will soon be further increased. The money expenditure on the new United States navy in the past sixteen years, for construction, equipment, and repair, has been about 160 million dollars. Of existing navies, that of England is by far the most powerful, Russia and Germany following her in the number and gross tonnage of their battleships. See J. W. King's *Warships and Navies of the World;* Lieut. F. H. Vesey's (U. S. N.) *Navies of the World;* and Mahan on *Sea Power*.

Naz'areth, the home of Jesus, anciently in Galilee, is still a small and flourishing town in Palestine. It is built partly on rocky ridges in a hilly country. It is not mentioned in the Old Testament, and in the early part of the Christian era was almost forgotten, the first pilgrimage to it taking place in the 6th century. The town contains a Latin convent, built on the supposed scene of the annunciation, while the Greeks have also built a commemorative chapel. There is also a Latin chapel, supposedly built over the workshop of Joseph, and a temple of the Table of Christ, containing the table from which the twelve apostles ate the last supper. The Virgin's well is just outside the town limits. The place has long been famed for the beauty of its women. The population is estimated at from 4,000 to 10,000.

Ne'bo, Mount, the highest point of the range of mountains to the east of Jordan, in the land of Moab. It was from its summit that Moses had his "Pisgah view" of Palestine. An ancient rude altar, probably as old as the time of the Amorites, was discovered here by Captain Conder in 1881.

Nebras'ka, one of the central states of the United States (one-half again as large as New York state), is bounded on the north by

South Dakota, on the east by the Missouri river, on the south by Kansas, and on the west by Wyoming. The country's surface is rolling prairie, level in the east and south, but in the west and north covered by the sand hills and an extension of the Bad Lands. The altitude of the western portion is 6,000 feet, falling to 2,000 feet at the east; consequently its principal rivers, the Platte, Niobrara, and Republican, flow in an easterly direction. Probably over one-fifth of its area (land surface) of 76,840 square miles, consists of improved farms, while the soil is mainly a black loam. The principal agricultural production is maize, but of late a great staple has arisen in the cultivation of the sugar beet. The manufactures are confined to the eastern and southern portions of the state, but although they are large and numerous, farming is the state's wealth. The state has a number of universities, colleges, and academies, and over 6,000 public schools. The University of Nebraska, at Lincoln, founded in 1869 (opened in 1871), has had a prosperous growth. Dr. E. Benjamin Andrews became its chancellor in 1900. The other chief colleges of the state are the University of Omaha (Presbyterian) at Bellevue; Doane college (Congregational) at Crete; Grand Island college (Baptist); Hastings college (Presbyterian); Gates college (Congregational) at Neligh; Nebraska Wesleyan university at Lincoln, and Creighton university at Omaha. Its principal cities are Omaha, Lincoln the capital, Beatrice, Hastings, and Nebraska City. Its population in 1900 was 1,068,539. The state was originally a part of the Louisiana Purchase and of the Northwest Territory. It became a territory in 1854, extending north to British America and west to the Rocky mountains, but before its admission as a state, in 1867, parts of it were taken to form Colorado, Idaho, and Dakota.

Nebras'ka City, the capital of Otoe county, Neb., lies on the west bank of the Missouri, 74 miles below Omaha. It is the seat of Nebraska college, and of the Academy of the Annunciation; it possesses a grain elevator and several manufactories. Population 7,380.

Nebuchadnezzar (*neb'u-kad-nĕz'er*), the most illustrious of Babylonian kings, was the son of Nabopolassar, the general of the Babylonian garrison at the time the Assyrian empire fell to pieces after the death of Assurbani-pal. The Babylonians then threw off the hated yoke of Assyria, and Nabopolassar was proclaimed king of Babylonia, in 625 B.C. Nebuchadnezzar succeeded him in 604 B. C., reigning 43 years, and was one of the greatest sovereigns who ever ruled over an ancient empire. He recovered the long-lost provinces of the kingdom, rebuilt palaces and temples, as well as the city of Babylon, captured and destroyed Jerusalem, taking the Jews into captivity. It is an astonishing fact that not a single mound has been opened by explorers in Babylonia, which did not contain bricks, cylinders, and tablets inscribed with his name.

Nebulæ (*nĕb'ū-lē*), are celestial bodies resembling, in appearance, small patches of white cloud. Hence the name, which is merely the Latin word for *small cloud*. Many thousands of these nebulæ have been measured and catalogued, but with the exception of two or three they are all invisible to the naked eye. Until 1864 — five years after the invention of the spectroscope by Kirchhoff and Bunsen — nebulæ were considered to be very distant star clusters, or clusters made up of stars so small as not to be resolvable by any existing telescope. But in the year mentioned Sir William Huggins examined a number of nebulæ with the spectroscope and found that they were not stars, but bodies composed of luminous gas, giving a spectrum of some six or seven bright lines. Two of these lines are fairly bright and are due, as has been proved by Keeler at the Lick observatory, to a substance not yet discovered on the earth. The brightest of all nebulæ is the one in the girdle of Andromeda; the one in the sword-handle of Orion can also be seen at times by the naked eye.

Planetary Nebulæ is the name given to those which show a more or less well-defined disc. It is not impossible that nebulæ are merely stars in their early stages of development, later to pass through the phases of *planetary nebulæ* and *nebulous stars*. See Scheiner's *Astronomical Spectroscopy*, translated by Frost.

Neb'ular Hypoth'esis is a theory advanced by three different men, Swedenborg (1688–1772), Kant (1724–1804), and Laplace (1749–1827), to account for the observed facts of planetary motion. The more important phenomena to be accounted for are as follows:

1. The orbits of all the planets are nearly circular and lie all nearly in one plane.

2. The direction of revolution about the sun is the same for all planets.

3. Except in the case of Uranus and Neptune, the direction of rotation of the planet on its axis is the same as its direction of revolution.

4. The larger planets rotate (not revolve) more rapidly.

5. The plane of rotation is not very different from the plane of the orbit.

6. The satellites generally have a direction of revolution which coincides with that of the planet's rotation.

To explain this rather orderly state of affairs it was supposed that the matter now constituting this solar system was at some earlier date in its existence distributed in the form of an immense nebula; and that as this nebula condensed, and therefore increased its rate of rotation (while preserving a constant moment of momentum) the centrifugal force became so great that some of the outer portions of the nebula were set free. That is,

the centrifugal force reached a point where it balanced the attraction of the rest of the nebula. The portions thus set free, whether as a ring or as a "hump," condensed still farther and formed the earlier planets. As the concentration of the original nebula proceeded, the rate of rotation kept on increasing and again "threw off" or set free other planets. So also with the planets themselves; as they became more and more compact, their rate of rotation increased sufficiently for them to set free their satellites.

In a general way this hypothesis explains in a very satisfactory manner the six facts enumerated above. With later modifications it explains even many of the anomalies of the solar system. See article LAPLACE.

For recent criticism of this hypothesis see article by Moulton in *Astrophysical Journal*, Vol. II. (1900).

Neck'ar, a river in Germany, flowing through Würtemberg and Baden; it is one of the largest tributaries of the Rhine, rises on the eastern slope of the Black Forest, and pursues a winding course for 250 miles until it enters the Rhine at Mannheim. It is navigable for about half its lower length. Tübingen, Heidelberg, Heilbronn, and Cannstatt are on its banks.

Neck'er, Jacques, a financier and minister of France, was born at Geneva, Sept. 30, 1732. At the age of fifteen he went to Paris as a bank clerk, and in 1762 founded the London and Paris Bank of Thellusson and Necker. He entered public life as a syndic of the French East India company and minister of the republic of Geneva at Paris, and about this time married. In 1773, he received the French academy prize for a eulogy on Colbert, and won great recognition by his *Essai sur le Commerce des Grains* in 1775. This was an answer to the free trade arguments of Turgot. After having loaned some money to the government, he was made director of the treasury in 1776, and director-general of finance in 1777. For five years he labored to improve the financial condition of France by readjusting the taxes, establishing state-guaranteed annuities and the present system of government pawnshops. His methods displeased the queen, however, and his publication of the *Compte Rendu*, a statement of the financial condition of France, in 1781, was made the cause of his dismissal. He thereupon withdrew to Geneva, but returned in 1787 and defended his *Compte Rendu*, for which he was banished from Paris. He was recalled to his office in September, 1788, but while winning popularity through recommending the summoning of the states-general, he proved wholly incompetent during the storms of the revolution. He declined the aid of Lafayette and Mirabeau, and on July 11, 1789, was ordered to leave France, but after the fall of the Bastille, three days later, he was recalled, only to resign voluntarily in September, 1790. He retired to his estate near Geneva, and died there on April 9, 1804. See *The Private Life of M. Necker*, by his daughter.

Nec'tar, the name given by most of the Greek and Roman poets to the drink of the gods. Homer describes it as of a red color, and says that its continued use was supposed to insure immortality. The sprinkling with nectar was supposed to confer perpetual youth, and it was used, in figure of speech, as meaning everything delightful and pleasant to the taste.

Nee'dle. The sewing needle must be one of the oldest implements used by man. Bone needles with eyes are found in the reindeer caves of France, and on the sites of the prehistoric lake dwellings of central Europe have been found many "eyed" needles of bone and of bronze, but only one of iron. Ancient bronze needles, 3½ inches long, have been found in Egypt, and there are surgeon's needles and thimbles which have been used in sewing, with ordinary needles recovered from Pompeii in the Naples museum. Savage races use needles of various materials, such as bone, ivory, wood, and metal.

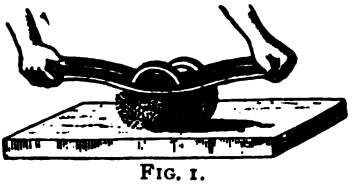


FIG. 1.

Steel needles were first made in Nuremberg in 1370, but the manufacture was not of much importance until about 1650. The early made needles were all square-eyed. Redditch, near Birmingham, is the seat of the needle manufacture in Great Britain, and great improvements have been made by the use of automatic machines and other new mechanical appliances. There are about twenty-two processes now used in the making of needles. First, fine steel wire is cut into double lengths; these are raised to a dull red heat and placed in loose bundles inside iron rings, to be straightened by rolling each bundle backward and forward on a face plate with a slightly curved bar (Fig. 1), through which the rings project. Next, the wires are pointed at both ends and then stamped in the middle, so as to produce the flat part of the eyes and the mark for the holes (Fig. 2); two oval holes are then punched by a vertical, belt-driven punching machine.

FIG. 2.

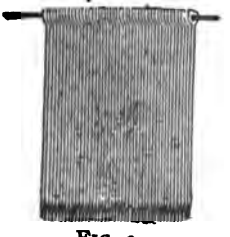

FIG. 3.

After being eyed the double needles, joined at the heads by thin fins, are "spitted" through their eyes on two wires flattened at one end so as to retain them. The burr made by the punch and die is now filed away, and after being broken in two between the heads and filed smooth, a row of single needles is left on each spit, as shown in Fig. 3. Next they are tempered by heating and dipping in oil, then polished and cleaned and sorted. It is estimated that 50,000,000 needles are made weekly in the Redditch district.

Nee'dle Gun. See RIFLE.

Ne'groes, a name given to the races inhabiting Africa, though it does not include all the inhabitants of that continent. The inhabitants of northern Africa, such as the Abyssinians, Nubians, and also the Hottentots of the south, do not belong to the negro race. The physical characteristics of the true negro are black skin, woolly hair, flat nose, and thick lips. Their skin is soft, and in the infant is a dull red, becoming black very soon. The negroes of the Guinea coast, who are rude savages, have a deep-black color and ugly features. Other tribes of the interior are tall and well formed, warlike, and have some ingenuity in making implements from iron. The skull of the negro is long and narrow, with low forehead, prominent jaws, and retreating chin. As a rule, they are of a low order of intelligence, mechanical in their work, but capable of great endurance. They are of a less nervous disposition than whites, more frequently color-blind, have smaller lungs and larger livers. The negro has long been a prey to the slave traffic, being captured in large numbers, and sold as slaves in other countries. The first slaves were brought to the United States in 1620, and this traffic was not discontinued until 1794, when it was prohibited by act of congress. The Spaniards began the trade, and King James and Queen Elizabeth both issued patents to companies. After 1794, and up to 1840, the trade was confined mostly from the African coast to the West Indies and Brazil. The coast of Guinea was the largest slave market, but inasmuch as they sold none of their own people but relied on those captured in war or by strategem, most of the slaves sent to the United States were of the pure negro type of the interior; while most of those taken to Brazil and the West Indies were closely allied to the Kaffir and Zulu stock of the east coast. The mortality among the negroes is greater than the whites, attributed in the south much to the fact of their low condition and inattention to the laws of health, in the north to their inability to withstand the cold and variable weather, as the diseases from which they suffer are mostly those of the respiratory organs. Therefore the publication, at frequent intervals, of accounts of long-lived negroes may be ascribed to the ignorance of their ages, and not to any exceptional tenacity of life.

In disposition the negro is, as a rule, cheerful and peaceable, unconcerned for the future, inclined to live in colonies, and is of emotionally religious instincts. Common among them even to the present day is the exercise of a certain form of witchcraft, called *Voodooism*, prosecuted by means of charms, philters, and fetiches.

The African negroes are quite ingenious in weaving mats and cloth and in the making of baskets from grasses; also, in constructing their huts and in making various utensils and implements for household use. They all acknowledge a supreme power, and are much given to a belief in witchcraft, charms, and spells. They have wooden images, which they think have power to drive away evil spirits, and to protect them from sickness and witchcraft. They are fond of music, and make various musical instruments of simple and rude character. Among the negroes in this country many become skillful in the use of musical instruments, especially the violin and the banjo. Since the emancipation of the slaves in this country, many individuals of the race have developed an ambition for education and the accumulation of property. In their education and elevation as a race much has recently been done for them by Booker T. Washington, himself a man of color, at the Tuskagee Normal and Iudustrial institute, of which he has been principal since 1881.

Nehemi'ah, who was a leader of the Jews after the exile, was a Jew holding the office of cupbearer to Artaxerxes when he heard, in some way unknown, of the unprosperous condition of Jerusalem. In the following year (444 B. C.), he obtained leave of absence and power to act as governor extraordinary of Judæa, and arriving at the city caused its walls to be rebuilt, enlarged the population by drafts upon surrounding districts, and brought back the Levites who had been forced to leave. On his second visit, twelve years later, he began new reforms, notably the movement against mixed marriages, the cleansing of the temple, a strict law of Sabbath observance, and a provision for the maintenance of the temple and priests. The Book of Nehemiah originally formed the closing chapters of the undivided work, Chronicles, Ezra, Nehemiah, containing the memoirs of Ezra and Nehemiah.

Nel'son, Horatio, Viscount, a celebrated English admiral, was born Sept. 29, 1758, at Burnham-Thorpe, in Norfolk, England. He entered the navy in 1770, and served with distinction for many years, earning one promotion after another. But on Aug. 1-2, 1798, he gained the brilliant victory, in the harbor of Abukir, over the French in the famous "Battle of the Nile," which covered him with glory. Never in recent times had there been a victory so complete — so overwhelming; and when Nelson, with his shattered fleet, returned to Naples, he was the object of an

enthusiastic adoration which knew no bounds. He was raised to the peerage, with the title of Baron Nelson of the Nile; parliament voted him a pension of $10,000 a year, and the East India company awarded him a sum of $50,000. Turkey and Russia sent him costly presents, and the king of Naples gave him the title of the duke of Bronté, in Sicily, with an estate worth $15,000 a year. On Jan. 1, 1801, he was promoted to be vice-admiral, and later, as viscount, he conducted the defense of the coast of England against the French. On the renewal of the war with France and Spain, in 1805, he was sent out to the Mediterranean in command of the English fleet, against the French vice-admiral, Villeneuve. What Nelson wanted was not merely an honorable victory gained by an inferior fleet, but the annihilation of the enemy. At daybreak on the 21st of October (1805), the two fleets met off Cape Trafalgar; deafening cheers broke from the British armament as the celebrated signal flew from the flagship, "England expects every man to do his duty"; and it is said that Villeneuve, as he heard the shout, exclaimed, "All is lost." The battle ended in a decisive victory of the English. The fleet of the allied enemies was totally destroyed, but Nelson, the greatest of England's commanders at sea, fell mortally wounded, having swept her foes from the ocean. Nelson's body was buried in a crypt of St. Paul's, London. A splendid monument has been erected to his memory in the cathedral. See Southey's *Life*, and *Nelson's Dispatches and Letters*, edited by Sir N. Harris Nicolas.

Nel'son River, a river in the northwest territories of the Canadian Dominion, which has its source in the north end of Lake Winnipeg, and flows 400 miles in a northeasterly direction into Hudson bay, discharging an immense volume of water. It is navigable for 127 miles from its mouth, but for only 70 or 80 miles for large steamers. Its chief feeder is the Saskatchewan, which empties into Lake Winnipeg.

Nel'son, William, an American general, was born at Maysville, Ky., in 1825. He entered the navy and in 1854 had attained the rank of commander, but at the outbreak of the Civil war he was transferred to the army, and in 1861 was appointed brigadier-general. He was in command of a division at Shiloh, in April, 1862. As the result of a private quarrel, he was killed by Gen. Jefferson C. Davis, at Louisville, Ky., Sept. 29, 1862.

Nem'esis, said, by Hesiod, to be the daughter of Night, was at first the embodiment of righteous moral feelings, or of the conscience. Later on, Nemesis was regarded as the power which balanced the fortunes of the people and taught them to reverence the immortal gods. From this was evolved the latest conception, that of the avenger of wrong. She was at first represented as a young virgin, and later as clothed in a tunic, sometimes with sword in hand and a wheel at her feet, or in a chariot drawn by griffins. Several fragments of Phidias' statue of Nemesis were discovered in 1890, in the famous temple of Nemesis at Rhamnus, Africa.

Ne'on. See ARGON.

Ne'pomuk, John of, the patron saint of Bohemia, a martyr of the seal of confession, was born near Pomuk about 1330, and after studying at the University of Prague, and taking holy orders, was appointed confessor to Sophia, wife of King Wenceslaus IV. For his refusal to reveal the confessions of the queen to the king, John was tortured, securely bound, and thrown into the river Moldau in March, 1383. He was canonized by Pope Benedict XIII. in 1729, and his memory, deeply cherished, is celebrated on May 16.

Nep'tune, the Roman god of the sea, was like all the other gods of mythology, merely a name. This was derived from Nethunus, the sea-god of the Etruscans. He is also identified with the Greek sea-god Poseidon. The figure of a bearded man standing in a shell drawn over the sea and holding a three-pronged spear, or trident, is his usual pictorial representation.

Nep'tune. See PLANETS.

Nerbud'da or **Narba'da,** an Indian river of about 800 miles, with a drainage of 36,400 square miles, rises on the Amorkantak plateau, 3,493 feet above sea level, and flows west through central provinces and the great channel between the Vindhya and Satpura mountains into the gulf of Cambay. It is navigable for only about 80 miles from its mouth. The Hindus consider it a sacred river and look upon a foot journey from mouth to source and back as a meritorious act.

Ne'ro, the last of the Cæsars and emperor of Rome from 54 to 68 A. D., was born at Antium, Dec. 15, 37. His mother became the wife of the Emperor Claudius, who adopted him, and on the emperor's death he was declared emperor by the Prætorian Guards instead of Claudius' own son, and this choice was ratified by the senate and provinces in 54. His reign, although opening well and moderately, soon became one of crime, debauchery, and tyranny. He caused Britannicus, Claudius' son, to be poisoned, brought about the murder of his own mother, and finally divorced and murdered his wife. All this was accompanied by wars and insurrections,—in 61 A. D. an uprising in Britain, which was suppressed, and in 62 the war with the Parthians and Armenia. In 64, a great fire destroyed nearly two-thirds of Rome, and many historians say that Nero applied the torch and sat far away admiring the scene. Nero thereupon used the sect of Christians as scapegoats, and had many of them put to death. Through the high-handed imposition

of taxes, he rebuilt Rome and erected the "golden house" for himself on the Palatine hill. A conspiracy against him in 65 failed and caused the death of Seneca and others. He kicked his second wife to death and afterward offered his hand to Antonia, the daughter of Claudius, who, upon refusing him, was put to death, as was also the husband of Statilia Messalina, whom he thereupon married. His inordinate vanity caused him to believe that he was everything brilliant, as is witnessed by his last words: "What an artist is lost in me!" In 68, the Prætorian Guards rose against him and in conjunction with the Gallic and Spanish legions, proclaimed Galba emperor. Thereupon Nero fled from Rome and was declared an enemy of his country, and to save himself from execution, he committed suicide June 9, 68. See W. Wolfe Capes' *Early Roman Empire*, and Merivale's *History of the Romans under the Empire.*

Nerves, the fibers of white nervous matter connecting the different parts of the body with the central nervous system. Two kinds of nervous tissue are recognized,—the white and gray. The white is composed of fibers, the gray is largely made of nerve cells located in centers. The nerves are merely conductors of the nervous impulses that arise within the nerve-cells. Nerves make their first appearance in the animal kingdom among the jellyfish as parts of the primitive nervous system. They are at first strands of protoplasm connected with the nerve-cells from which they grow. They become associated in bundles, bound together by connective tissue, and thus form the white cords that run amongst the muscles and other parts of the body. In the human body, there are twelve pairs of cranial nerves connected with the head, and thirty-one pairs of spinal nerves connected with the spinal cord. Those of the head are much more complex than those of the spinal cord, but they are believed to be derived from a simpler condition in which they were equivalent to them. They are now so much modified that it is difficult to understand them. The thirty-one pairs of spinal nerves come from two roots closely joined to the spinal cord. These are called sensory and motor roots, respectively, because those at the back contain sensory fibers and those in front motor fibers. Recent observations have established a great law in reference to the development of nerves, viz., the sensory fibers arise outside and grow into the central nervous system, and motor fibers start within the central nervous system and grow outward. This applies even to the highest developed sensory nerves—for example, the fibers of the optic nerve begin in the retina of the eye and grow toward the brain, instead of starting in the brain and growing outward to the eye. Besides sensory and motor fibers there are those that regulate the nutrition and the tone of organs, called trophic nerves, those that carry impulses which stimulate secretion, called secretory nerves, and some others. The twelve pairs of cranial nerves are as follows: The first pair connected with smell; the second pair with sight; the third, fourth, and sixth pairs are connected with muscles that move the eyeball. The fifth pair go to the teeth, tongue, and face, the seventh pair to the muscles of the face, the eighth pair to the ears, the ninth pair to the tongue, as nerves of taste, and to the muscles of the pharynx. The tenth pair (pneumogastric) are very important and widely distributed, going to the heart, lungs, stomach, and intestines. The eleventh pair supply certain muscles in the neck, and the twelfth pair form the muscles of the tongue. Besides all these, are nerves belonging to the sympathetic nervous system. The object of nerves is to connect the different parts of the body with the controlling nervous system. They are simply conductors and not originators of nervous impulses.

Nes'tor, the great Greek counselor of the Greeks, was born in Messenian Pylus, the son of Neleus and Chloris, and became the husband of Eurydice. In his youth he fought valiantly against the Arcadians, Epeans, and Centaurs, and in his older years was famed for his wisdom. He joined the war against Troy with sixty ships, and although an old man, remained through the war, returning to Pylus at its close and ruling as governor until his death.

Nestor'ians, a sect formed in the 5th century by the followers of Nestorius, patriarch of Constantinople in 428 A. D., but who was deposed in 431 because of his peculiar views as to the divine and human nature of Christ. After it was driven out of the Roman empire, the sect of Nestorians was extended into Persia, India, and even China. In Asia Minor, under Babæus, bishop of Seleucia (498–503), and his successor, the sect grew rapidly and produced many learned theologians, philosophers, and physicians, such as Hippocrates and Galen. Under the rule of the caliphs the Nestorians enjoyed toleration, and spread in Arabia, Syria, and Palestine. The Prester John of romance was a Christian of this color, and tradition has it that Mohammed learned what he knew of Christianity from a Nestorian monk. The sect reached the height of its prosperity in the middle of the 13th century, but after the persecutions of Tamerlane they dwindled away. They are now a poor and illiterate race numbering less than 70,000. Their chief seat is in Persia and in the mountains of Kurdistan.

Neth'erlands. See HOLLAND.

Net'tle, species of urtica, a genus containing about 30 species widely distributed. The best-known nettle is *U. dioica*, known as the "stinging nettle," which is a native of Eu-

rope and Asia, but has become extensively naturalized in the United States. It is densely beset with stinging hairs.

Neuchatel or **Neufchatel** (*nu'shă'tĕl'*), the chief town of the canton of Neuchâtel in Switzerland, is situated on the northwest shore of the lake of Neuchâtel, about 85 miles from Geneva, and is noted for its charitable, educational, and artistic institutions. It manufactures mainly watches, jewelry, lace, etc., but not the Neufchâtel cream cheese; this comes from a small Norman town called Neufchâtelen-Bray. Population 20,697.

Neuchatel', Lake of, is all that is left of the large body of water which at one time covered the whole lower valley of the Aar, in Western Switzerland. Its greatest dimensions are 25 miles long and 6 wide, and its area 92 square miles. It is fed by the Thièle and the Reuse, and drained by the Thièle through the lake of Bernice and thence into the Aar. Its elevation is 1,424 feet above sea level, and its northwestern shore is rich and cultivated, but the opposite side is barren and rocky. It has pleasing though not remarkable scenery, and is famous mostly for the discovery of the ancient remains of water dwellings in it. The capital city of the canton, Neuchâtel, is on its banks.

Neu'ville', Alphonse Marie de, a popular follower of the French school of battle-scene painters, was born at St. Omer, May 31, 1836. He studied under Delacroix and painted a series of pictures of the Crimean, Italian, and Mexican wars of France. In the war with Germany, he served in the ranks and painted the series from experience. He also excelled as an illustrator of books. Guizot's *History of France* is illustrated from his designs. He died at Paris, May 19, 1885.

Ne'va, a northern Russian river; rising in the southwest corner of Lake Ladoga, it passes through St. Petersburg and empties into the bay of Cronstadt, in the gulf of Finland. It drains lakes Ladoga, Onega, Ilmen, and others. Its total length is 40 miles and the width varies from 180 to 4,000 feet. It is frozen over for about five months in the year.

Neva'da, one of the Pacific states of the United States, lies between Idaho and Oregon on the north, and Utah and Arizona on the east, and California on the south and west. It is 500 miles long and 300 wide between its farthest points, and although the sixth largest of all the states and territories, it has the least population, 42,335 in 1900. The largest part of the state is included in the Great Basin, or what was at one time the bed of a large inland sea. Its land surface has an area of 109,740 square miles, that is, almost twice that of Illinois. This part is dry and barren, with the exception of the regions immediately around Walker, Humboldt, Carson, Pyramid, and other lakes, and is traversed by high mountains. The mean elevation of the state is about 4,000 feet. The chief industry is mining, enormous quantities of silver having been found in several regions in the state. Its principal river is the Humboldt, which is about 350 miles long. The dry atmosphere is clear in winter, but in summer is filled with small particles of alkaline dust. The rainfall is exceedingly light, therefore the vegetation is very scant though hardy. Silver was first discovered in 1859, and the state was separated from Utah in 1861, and admitted as a state in 1864. The principal cities are Carson City, the capital, Virginia City, Reno, and Gold Hill. About 9,500 Indians are still on the reservations in the state.

New Al'bany, an important manufacturing city of Indiana, county seat of Floyd county, is on the Ohio river, nearly opposite Louisville. It has extensive glass works, cotton, woolen, hosiery, flour, rail, planing and rolling-mills, stove foundries, and other industries. It has a college, and excellent public schools. Population 20,628.

New Bed'ford, a city and port of entry in Massachusetts, is in Bristol county, on the Acushnet estuary, 56 miles south of Boston. For a century prior to 1854, it was the principal whaling center of the world, sending out over 400 vessels and receiving 60,000 barrels of sperm, and 120,000 of whale oil annually. Since that year, however, manufactures have claimed its attention, and it now contains cotton mills of 500,000 spindles, foundries, oil refineries, drill, cordage, boot and shoe, flour, glass, and plated ware factories. It has many very handsome private residences, and a population of 62,442.

New Bright'on, a village and beach resort of New York, is on Staten island, six miles from New York city. It is a summer resort, containing, for the most part, only villas, but has also a paper factory and dye works. It has frequent water connection with New York, of which city (Greater New York) it is now a borough.

New Brit'ain, a manufacturing town of Connecticut, in Hartford county, has two large parks and contains the state armory and normal school. The city has manufactories of hardware, cutlery, locks, hosiery, jewelry, etc. Water is supplied from a reservoir of nearly 200 acres. Population 25,998.

New Bruns'wick, an eastern province of the Canadian Dominion, abuts on the gulf of St. Lawrence, having Nova Scotia on the east and the Gaspe peninsula of Quebec on the northwest, with the state of Maine for its southern neighbor. With its many bays and inlets, it has a coast line of over 400 miles in extent, on the Northumberland strait, on the gulf of St. Lawrence, and on the bay of Fundy. New Brunswick is famed for its fisheries and canneries, as well as for its

lucrative lumber trade and its considerable industry in ship-building. The country is well watered, notably by the St. John river, navigable from near its mouth (at low tide) for steamers for a distance of 90 miles to Fredericton, the capital; thence for 70 miles further to Woodstock. The other chief rivers are the Miramichi, the Restigouche, and the Richibucto. On the Miramichi are the towns of Newcastle and Chatham. The city of St. John, the chief seaport, lays claim, with its rival Halifax, to the commercial designation of "the Liverpool of Canada." Its site was known to De Monts and Champlain, who visited it in 1604, though it was not occupied until thirty years later. Here, in 1834, La Tour erected a trading fort, which for many years became the disputed possession of the rival governor of Acadia, and the scene of the heroism of the Lady De la Tour. The harbor also figures prominently in naval history, being the scene of many sharp engagements between English and French war-ships, and between the latter and the armed vessels of the spirited colonists of New England. After the Revolutionary war, to St. John came a British fleet bringing 5,000 "United Empire Loyalists," who had voluntarily exiled themselves, to live under the British flag. As late as 1862, British troops were in garrison here, during the excitement incident to the *Trent* affair, though they were then withdrawn, and St. John has since then taken to maritime and commercial, rather than to military, pursuits. Both the city, and some inland districts of the Province, have suffered heavily at various times from destructive fires. Fredericton, the capital, is a charming little town, a considerable social center, and the seat not only of the Provincial Legislature, but of the university of New Brunswick, whose charter dates from 1828. It is also attractive to sportsmen as a rallying point and base of supplies, for the fine fishing and hunting grounds of the upper St. John. The other chief towns are Moncton, Kent, Dorchester, and Bathurst. Population 331,093.

New Bruns'wick, the capital of Middlesex county, N. J., lies on the Raritan river at the head of the Delaware and Raritan canal. It contains many churches and Rutger's college (1771), observatory, agricultural college, and model farm. It manufactures great quantities of india rubber, also hosiery, lamps, needles, etc., and has iron and brass foundries. Population 20,006.

New Caledo'nia, a south Pacific island belonging to France, lies between the Fiji islands and the east coast of Queensland. It is about 240 miles long and 25 wide and has an area, with its dependencies, of 7,700 square miles. The ground is much broken by irregular mountain chains, but in the valleys it is fruitful, yielding cocoanut, maize, tobacco, etc. It has rich mineral resources in copper, cobalt, antimony, and chrome, and exports these, together with preserved meats, copra, and coffee to England, while it imports wines, flour, drapery, groceries, machinery, and coal. It has a population of 53,000, of whom 30,650 are native Kanaques, and 7,544 are convicts.

Newcastle, a manufacturing city of Pennsylvania located on the Shenango river, fifty miles northwest of Pittsburg. The production of steel is the principal industry. Large blast furnaces, rolling mills, tin plate, wire and nail mills furnish employment for thousands of workmen. Glass, brick, and paper are also manufactured. Population 28,339.

New Guin'ea (British), Governor, Geo. Ruthven Le-Hunte, C. M. G. British New Guinea comprises the southeastern part of the island of Papua, or New Guinea, lying directly north of Australia, and separated from it by Torres strait. The area of the entire island is computed to be 234,768 square miles; the British portion is 90,540 square miles, with a population of about 350,000. The island, next to Australia, is the largest in the world, though the native tribes have only of late been reduced to order. The German territory is known as *Kaiser Wilhelm's Land* and embraces some 70,000 square miles. *Dutch New Guinea* forms another section of the island, with an area of 151,790 square miles. The various districts annexed by European governments are administered as protectorates by resident governors. The country is believed to contain valuable timber; the coco and sago palms are plentiful, and sandalwood, ebony, rattans, gums, and other products are found. Gold is also found and to some extent worked. Trade with the British possession is confined to Queensland and New South Wales.

New Hamp'shire, one of the original thirteen states, is called the "Granite State," and lies south of Quebec, west of Maine, north of Massachusetts and east of the Connecticut river, and has an area of 9,305 square miles. The White mountains extend nearly its entire length and the principal peaks are Washington, Adams, Jefferson, Madison, and Monroe. The principal rivers are the Merrimac, which furnishes more power to cotton and woolen mills than any other river in the world, the Connecticut, and the Piscataqua. Hay, maize, oats, and potatoes are the chief products of a limited farming industry, but manufacturing is carried on to a great extent. The largest cities are Manchester, Dover, Concord, and Nashua. The state has ten counties, sends two members to congress and elects its governor every two years. New Hampshire was first settled at Dover and Portsmouth in 1623. At different periods it belonged to Massachusetts, but from 1741 to 1775 it was under a royal governor. It adopted a constitution in 1784 and in 1788 was the ninth state to ratify the national constitution. Population 411,588.

New Ha'ven, the largest seaport and city of Connecticut, stands at the head of New Haven bay. It has broad, shaded streets, public squares, parks and gardens, and handsome public buildings. It also contains Yale college, Sheffield Scientific school, and Hopkins Grammar school (1660). Its chief consequence is as a manufacturing town, having large works in hardware, wire, locks, clocks, cutlery, firearms, india rubber goods, carriages, furniture, paper, and matches. The city was settled by an English company in 1638 and was unconnected with Connecticut until 1662. It was incorporated as a town in 1665 and received a city charter in 1784. Until 1873 it was jointly the capital with Hartford. Population 108,027.

New Heb'rides, a chain of islands in Melanesia, west of Fiji and northeast of New Caledonia in the Western Pacific, running from northeast to southwest. There are over thirty islands in the group, but only about twenty are populated. All are of volcanic origin, and some still have active volcanoes upon them. The largest are: Espiritú Santo, 70 miles by 40; Malikolo, 56 by 20; Ambrym, 22 by 17; Sandwich, 30 by 15; Erromango, 30 by 22, and Tanna, 18 by 10. They are all high and well-wooded, and the moist, clear, and warm atmosphere allows the cultivation of tropical fruits and products, such as the yam, taro, banana, breadfruit, sugar cane, arrow-root, and cocoanut. The people, who belong to the Papuan and Polynesian races, are cannibals. The chain was discovered by the Portuguese, Quiros, in 1606, and explored by Captain Cook in 1773. They are claimed by the British and by the French, and for the protection of life and property are under the authority of a mixed commission of French and English naval officers, on Pacific stations. Population estimated at about 80,000.

New Jer'sey is one of the thirteen original states and lies south of New York, west of the Hudson river, Raritan bay, Staten Island sound and the Atlantic, north of Delaware bay, and east of the Delaware river. It is the fourth smallest state in the Union, and has an area (land surface) of 7,525 square miles. Some portions of the Appalachian system extend into the northern part of the state, but no elevations in the state, outside of these, exceed 1,500 feet in height. The central part of the state is rich and fertile, the total farm acreage being about 3,000,000, and the chief products corn, oats, wheat, rye, potatoes, hay, and cattle. Its mineral products are iron ore, limestone, zinc, and slate; and glass, pottery, machinery, leather, silk, and sugar are its manufactures. Its principal cities are Trenton (population 73,307), the capital; Newark, New Brunswick, Jersey City, Paterson, Hoboken, Bayonne, East Orange, Atlantic City, and Elizabeth. The Atlantic coast has many small towns which are frequented as summer resorts.

New Jersey does liberal things for education, her annual public school expenditure amounting to close upon $2,500,000. Besides her public school enrollment of 325,000, she maintained, in 1900, 90 high schools with 460 teachers and over 10,000 students. The state has also three normal schools, two schools of technology, and four colleges, besides Princeton university, with a faculty of 100, and a student body numbering close upon 1,300, including graduates of the year (1899–1900), and academic and scientific undergraduates. The university enjoys an annual income of $275,000, and has a present endowment of about $2,500,000.

The state was settled at Bergen, by the Dutch, in 1617. In 1623, some English built a fort on the site of Camden, but were driven away by the Swedes in 1638. In 1664, Charles II. granted the state to the duke of York, and by him to Lord Berkeley and Sir George Carteret, who sold it to some Quakers and William Penn. In 1702, it was returned to the crown, and from 1738 had its own royal governors. Population 1,883,669. See the *History of New Jersey*, by Raum.

New Lon'don, a seaport of Connecticut, lies on the right bank of the Thames, three miles from its mouth, has a courthouse, city hall, and custom house, and includes woolens, sewing silk, agricultural machinery, hardware, and crackers among its manufactures. It has a good harbor and many vessels engaged in sealing and fishing. The town was settled in 1645 and burned by Benedict Arnold in 1781. Population 17,548.

New Mex'ico, a southwestern territory of the United States, lies south of Colorado, west of Oklahoma and Texas, north of Texas and Mexico, and east of Arizona, and has an area (land surface) of 122,460 square miles. The state is traversed by the Rocky mountain system, many peaks of the Santa Fé, Las Vegas, Taos, and Sierra Madre ranges rising to 12,000 feet. The ranges are divided by deep cañons and ravines. The principal wealth consists in its minerals, copper and iron, found all through the state, and its coal-beds. Its rivers flow into the gulf of Mexico and west to the Pacific, the chief being the Rio Grande, Pecos, Little Colorado, San Juan, and Gila. The soil is fertile in the valleys, and cattle-raising is one of the main pursuits. When the Spaniards first settled at Santa Fé, they found people living in substantial houses built long before; but in 1822 the people seceded from Spanish rule, and in 1848 a part of the territory was acquired from Mexico by the treaty closing the war, and the rest by purchase and cession from Texas. The territory originally included Arizona and part of California and Colorado, but was given its present boundaries in December, 1850. Population 195,310, of which 100,000 are Mexicans and nearly 40,000 Indians.

New Orleans, the largest city of Louisiana, lies on both sides of the Mississippi, about 107 miles from its mouth, and derives its name of Crescent City from the shape that two bends in the river give it. Its situation as the southern outlet makes it the second city in the United States in importance as to exports. It is the terminus of three canals, and of six or more large railroads, and three local lines, while over twenty lines of steamships connect it with other American and foreign ports. Since 1875, New Orleans has made great progress in manufactures, particularly in cotton goods, cotton-seed oil, machinery, lumber, furniture, fertilizers, sugar refining, rice milling, etc. New Orleans is built upon ground from two to six feet below the surface of the river, and is protected from the rising waters by a system of levees along the water front. It has no sewers, and the drainage is, for the most part, through open gutters in the streets. It contains the United States mint, an old Gothic church (a good sample of Creole-Spanish architecture), and a new custom-house, besides the largest charity hospital in the United States. It has good public schools, maintained at an annual cost of $450,000, with a teaching force of 702, and an attendance of 31,521 pupils. Tulane university, with 77 professors, and having under its control the Sophie Newcomb memorial college for the higher education of girls; the College of the Immaculate Conception, and four colleges for negroes. The Howard memorial, Tulane and Louisiana state libraries, all free, contain together 120,000 volumes. The place where the city is built was first visited by Bienville in 1699. He founded the city in 1718, and made it the capital in 1726, which honor it held until 1880. It was ceded to Spain by France, but in 1765 the people established a separate government only to have the leaders of the movement shot in 1769. It was incorporated as a city in 1804. It was the scene of the battle of New Orleans in 1815, and was captured by Farragut in 1862. The people are of all nations, only nineteen per cent. being of American or English descent. Seventeen per cent. are Creoles, a term applied to people born in the southern states of French, Spanish, or Portuguese ancestors. The Creole dialects are corruptions of French, Spanish, and Portuguese. Mr. Cable's stories revealed to English readers the singularly quaint charm of the phraseology and manners of the Creoles of Louisiana, who are of French descent. Besides the American and Creole inhabitants, the population is made up of Germans, Irish, Italians, Spaniards, Scandinavians, Jews, Negroes, mixed races, Indians, Chinese, and Malays. Population 287,104.

New South Wales, the oldest colony in Australia, formerly included Queensland, Victoria, South Australia, Tasmania, and New Zealand, but now its area is 310,700 square miles, and its population, including 10,000 Chinese, blacks, and half-caste natives, 1,361,120. The Australian Alps, the Blue mountains, the Liverpool range, and the New England hills, are some of the mountains scattered over the country, and the Murray, Lothian, Nepean, Clarence, Shoalhaven, Darling, and Macquarie are some of the chief rivers. The colony was established in 1788 by a party of transported prisoners from England. Then land was given to free colonists, and transportation ceased in 1840. Whereon followed a great social advance, stimulated by the discovery of gold in 1851. The country is covered with trees, such as the eucalyptus, palm, pine, and cedar, and vegetation is very rich. Kangaroos infest this as well as other regions in Australia; there are many lizards and snakes, and birds of beautiful plumage.

Gold was first worked, in 1851, near Bathhurst, and is now found in an area covering 70,000 square miles, to an annual value of nearly $9,000,000. Silver abounds in the Barrier Range, and copper, tin, bismuth, manganese, antimony, mercury, zinc, cobalt, and alum are mined, and precious stones are found in the granite formations. Yet the greatest mineral wealth is found in the coal-fields, extending over 24,000 square miles, and yielding 4,600,000 tons in 1899. Sheep and cattle are extensively raised on the ranges, there being over 50,000,000 sheep now in pasture. The export of wool exceeds 150,000,000 pounds per year. While 140,000,000 acres are devoted to pasturage, only 1,000,000 are given to farming, therefore, the agricultural output is very small. Other exports include, besides gold, coal, and the great wool crop, hides and skins, leather, tallow, and meat, preserved and frozen. The colony has the largest trade, on account of its harbors and resources, of any of the Australian colonies. In 1900, it had 2,771 miles of railroad open for traffic. Public schools maintained by the state are now established, entirely unconnected with the church. Higher education is represented by the university of Sydney, with a staff of about 50 professors and lecturers, and 519 students. The laws of New South Wales are administered by a governor appointed by the crown, an executive council, a legislative council and legislative assembly. See T. A. Coghlan's *The Wealth and Progress of New South Wales.*

New Stars, sometimes called "temporary stars," are bodies which suddenly make their appearance in the heavens, rise rapidly to their full brightness, and soon begin to diminish until they can be seen only with a telescope or, perhaps, not at all.

The earliest one of which we have any account is that of 1572, generally known as "the star of Tycho Brahe." But it is only since the invention of the spectroscope that this class of stars has come to be of especial interest. The new star in the constellation of Corona Borealis, discovered by Birmingham, May 12, 1866, was examined spectroscopically by Huggins and Miller. They found that it possessed both a dark line spectrum and a bright line spectrum, differing in this respect from nearly all the other stars. The next new star was that in the constellation of the Swan, known as "Nova Cygni," discovered Nov. 24, 1876, a red star of the 3d magnitude. Two years later it was fainter than the 11th magnitude. "Nova Andromedæ" was discovered August, 1885; and "Nova Orionis," in December of the same year. But the star which Anderson at Edinburgh discovered Jan. 24, 1892, far exceeded all previous new stars in interest, because the power of the spectroscope had been increased in many ways since the previous stars were observed. For a full account of this star, called "Nova Aurigæ," the reader is referred to Scheiner's *Astronomical Spectroscopy*, where its interesting spectrum is described in detail. The next, and only other important new star was also discovered by Anderson, this time in the constellation of Perseus, Feb. 22, 1901. Many theories have been advanced to explain this curious phenomenon; but the one which at present seems most probable is that advanced by Seeliger, viz., that the new star is produced by some dark body rushing into a meteor swarm or a nebula, the impact of small particles being sufficient to bring the dark body to incandescence.

New Year's Day, is the first day of the year. It is usually now celebrated by feasting and the interchange of presents. The Jews, Chinese, Egyptians, and Mohammedans, while differing as to the time of celebration, all celebrate the first day of the year in their respective calendars. In the Christian era, Christmas day, Easter, and the 1st of March, have each in turn been celebrated, and it was not until late in the 16th century that the 1st of January was universally accepted. In Scotland, France, and in Italy, New Year's day is of more importance than Christmas, but in other countries the latter has superseded the former as a day of rejoicing and of making gifts.

New York, the first state in point of population in the United States, is called the Empire State and has an area of 49,170 square miles. The Appalachian system enters the state in the form of the Adirondack mountains in the northeast, and are cut off from the Catskills by the Mohawk and its valley. The Taconic range of New England enters near the south, and passes on to New Jersey, but is cut by the Hudson, here forming the famous Highlands. The state has some iron, lead, copper, and zinc mines, salt springs, and mineral and medicinal springs, such as those of Saratoga, Ballston, Sharon, Richfield, New Lebanon, and Avon. The most important river is the Hudson, and others are the Mohawk, Black, Genesee, and Niagara. The Susquehanna and Allegheny rise in the southern part of the state. New York has many beautiful lakes, first in point of beauty being Lake George and the Adirondack lakes, but the lakes and rivers breaking into falls, the greatest of all being Niagara, and the Genesee, Trenton, Kaaterskill, Cohoes, Ticonderoga, and Watkin's Glen, make the state famed for its beautiful scenery. When the whites first settled in this territory they found it inhabited by the Iroquois Indians. Just at this time Champlain discovered the lake that bears his name, and Hudson explored the river Hudson in 1609. Not many years later, the Dutch founded some settlements, but in 1664 were forced by the English to give up their city of New Amsterdam, and its name was changed to New York. From that time to the Revolution it belonged to the English.

During this period, to the close of the Revolutionary war (1674–1783), New York was under the rule of over thirty colonial English governors, some of whom had many difficulties to contend with. There were, at periods, difficulties with the Indians, including Iroquois raids and menacing movements on the border settlements of the colony; there were also the harassing hostilities of the French and their dusky allies in 1755–63, the period of the French and Indian war; besides collisions, during the era just preceding the Revolution, between the colonists who had grown restive under monarchical rule and the harsh sway of gubernatorial authority. New York was also the scene of considerable fighting in its northern area, during the War of 1812–14, a conflict which bore heavily upon its border settlements from the Niagara region to the eastern end of Lake Ontario, and on the St. Lawrence from Ogdensburg to the district around Lake Champlain. With peace came the era of canal construction, and later the beginnings of the railway system, and improved highways, and increased settlement throughout the state. It bore also its share of the burdens entailed by the Civil war and the four years of prolonged and calamitous strife. Since then its progress has been both rapid and substantial, and well entitle it to the fame it now possesses as the Empire State in the Union.

In manufactures the state stands foremost in the Union, and is the center of railroad traffic. In 1900, it had a total mileage of railroads of 8,230 miles, and a total foreign trade through its ports in value aggregating $1,250,000,000. It has large mining activities in iron ore, chiefly of magnetite and hematite, besides a large output of granite, marble, slate, limestone, and sandstone. In agriculture, its annual yield is also extensive, especially in corn, wheat, barley, rye, hay, buckwheat, and potatoes. Its manufacturing industries are, moreover, vast, the state having over 3,550 industrial establishments, in which nearly 360,000 hands are employed.

The commerce of the state continues to expand, chiefly through the port of New York, and this demands increased facilities in the way of railroad and canal transportation. The canal commission of the state recommends the enlarging of the state canals, the building of branches, the improving of locks, and even the construction of a new canal, at a cost of sixty million dollars, so as to meet the expanding trade of the state and give increased facilities for water communication with the Great Lakes. These enterprises are part of the current activities of the governing body of New York state.

The returns of the department of public instruction for 1900, show that in that year nearly $33,500,000 was expended by the state for public school education, and of that sum close upon $20,000,000 was apportioned for teachers' salaries. The number of teachers employed during the year was 31,768, while 1,200,575 children attended the schools. The entire public school property of the state was, in 1900, valued at $81,768,500, the number of public schools being 11,931. In the same year, there were 34,105 boys and 42,260 girls taught in the secondary schools, the teaching staff in these numbering 3,888 (1,369 male, and 2,519 female teachers). The expenditure for the year on these secondary schools, amounted to $6,036,375, while the value of the school property was estimated at $28,412,000. The state also made a considerable appropriation during the year for the maintenance of school libraries, the number of which was 1,035, containing over 1,550,000 books. For higher education, $7,660,000 was, moreover, expended in 1900, on the students (nearly 30,000 in number) reported as attending New York colleges, and the technical and professional institutions of the state.

The chief institutions for higher education in the state embrace, besides New York university, Columbia university, Manhattan college, St. John's, St. Francis Xavier, and the College of the City of New York — all having their seat in New York city. Cornell university, at Ithaca; the University of Rochester; Colgate university, at Hamilton; Hobert college, Geneva; Hamilton college, Clinton; Syracuse university; Union college, Schenectady; Niagara university; Canisius college, Buffalo; Alfred university; St. Stephen's college, Annadale; and St. Bonaventure college, Allegany. At Brooklyn there are, besides the Polytechnic institute, Adelphi, St. John's, and St. Francis colleges, and a number of special institutions throughout the state for higher instruction in law, medicine, theology, agriculture, and practical science. At New York city, there are the theological seminaries of the Presbyterian (Union seminary), the Protestant Episcopal, and the Jewish communions; at Rochester, a Baptist denominational seminary; at Auburn, a Presbyterian theological seminary; at Hartwick, a Lutheran, and at Yonkers a Roman Catholic (St. Joseph's) seminary. Most of the universities named in the state have, moreover, law and medical departments, while a few have schools of pharmacy and dentistry, and one, at least (Cornell, Ithaca), a veterinary college, besides agricultural and mechanical courses. There is also, at New York city, a teachers' college, or normal school, for professional training in educational methods.

Its principal cities are New York, Albany, Brooklyn, Buffalo, Troy, Syracuse, Rochester, Utica, Binghamton, and Ogdensburg. Population 7,268,012. The capital is Albany.

New York City, the largest city in America, and in respect to both area and population the second city in the world, stands at the head of New York bay. The original New York occupied the long, narrow Manhattan island, lying between the Hudson — here called North river — and East river, together with 12,100 acres on the mainland, separated from the island by the Harlem river and

Spuyten Duyvil creek. Manhattan island is 13½ miles long and averages 1⅞ miles in width, the area of the city being 41½ square miles. In 1897, however, the new and greatly enlarged city of New York was constituted, by consolidating the old city with Brooklyn and other cities and outlying territory. Under the new charter, the territory embraced within the new limits of New York comprises the former city of New York on Manhattan island, and the annexed territory in Westchester county, the former city of Brooklyn, coterminous with the county of Kings, the entire county of Richmond, and the portion of Queens county included in Long Island

city, the towns of Newton, Jamaica, and Flushing, and a part of the town of Hempstead. This territory is divided into these five boroughs: Manhattan, comprising Manhattan and the adjacent smaller islands; the Bronx, including the part of the former city of New York in Westchester county north of the Harlem river and Spuyten Duyvil creek, and the islands adjacent; Brooklyn, comprising the whole of Kings county; Queens, including the part of Queens county named in the act of annexation, revised by the legislature of 1899, and Richmond, which consists of the county of that name, including the whole of Staten island.

Sandy Hook, 18 miles south of the Battery, marks the entrance to the Lower bay, which covers 88 square miles. The narrows, a mile-wide strait, between Long island and Staten island, separates it from the Upper bay, which contains 14 square miles of anchorage. The Upper bay can also be entered by ships of light draught by the Kill von Kull, to the west of Staten island, and from Long Island sound, through Hell Gate Pass (which see) and down the East river. This inner bay, open throughout the year, is one of the finest and most beautiful in the world.

The first European whose eyes beheld the blue waters of this picturesque harbor was John Verrazani, a Florentine sailor, whose glimpse of it in 1524 was cut short by a storm. But in 1609, Henry Hudson sailed up the bay and also the river which bears his name. Five years later, the Dutch built a fort on Manhattan island, and in 1623 the settlement was named Nieu Amsterdam. In 1674, the British gained possession of Manhattan island, naming it New York, in honor of the Duke of York, afterward James II. of England. During most of the Revolutionary war, from 1776 to 1783, New York was held by British troops. From 1785 to 1789, it was the seat of government of the United States.

New York's prominence is due to its position as the gateway of North America. At the head of a magnificent harbor, having an immense water frontage, lined with hundreds of docks, while the New Jersey shore is similarly lined, it receives 66 per cent. of the imports of the country and sends out 44 per cent. of the exports.

In East river, on Ward's, Randall's, and Blackwell's islands, are the great charitable and other institutions of the city. In the harbor are three small islands — Governor's island, occupied by the United States government; Bedloe's island, on which stands the Bartholdi statue of Liberty, and Ellis island, where are now received the emigrants, until lately landed at the famous Castle Garden at the Battery. In some years almost half a million emigrants enter the port of New York.

The lower part of Manhattan below 14th street, known as old New York, which is still the most densely populated part of the city, abounds in crooked, winding streets. Above

14th street the streets and avenues are wide and regular. New York is more famous, perhaps, for noted streets than for noted buildings, Broadway, Wall street, Maiden Lane, Fifth avenue, the Bowery, and others being known everywhere. Noteworthy among public buildings are the city hall, post office, the Tombs (prison), produce exchange, Madison Square garden, and Academy of Design. Among the finest churches are the Reformed (Dutch) church, Fifth avenue and 48th street, held by some to be the finest piece of architecture in America; Temple Emanuel, St. Patrick's cathedral, Trinity church, and the new Protestant cathedral of St. John the Divine. Among the tallest and finest office buildings are the Park Row, New York Life, St. Paul, and Tract Society buildings. The main pleasure ground is the famous Central Park (which see). There are also many small parks—the Battery, Union Square, Madison Square, etc., and three large parks on the mainland—Jerome, Van Cortlandt, and Bronx. The long and narrow shape of Manhattan island has caused the building of tall brick and stone tenements, in which the poor, and many in easy circumstances, are so crowded that in parts of the East Side there are more people to the square mile than anywhere else in the world.

There are four parallel elevated railroads, running up and down the island, which carry 750,000 passengers daily. There are also numerous trolley lines. A four-track underground railway is now under construction at a cost of $35,000,000. The route begins at the city hall and continues up Elm st. to Lafayette place, thence to 4th av., up 4th av. to 42d st., through 42d st. to Broadway, thence up Broadway and the Boulevard to 104th st., where it branches into two sections, one continuing up Manhattan Island to Fort George and beyond to Marble Hill, near Kingsbridge, the second going to the east to Lenox av., up Lenox to 141st st., thence under the Harlem river into the Bronx as far as Bronx Park. An extension of this road is projected which is to extend from New York city hall to Brooklyn, passing under the East river at South Ferry. Four railroads enter the city by a viaduct and tunnel from the north; but most of the trunk lines have their depots on the New Jersey shore. The Pennsylvania Railroad Company has projected a tunnel under the Hudson, which is to extend under the island and East River to Brooklyn and Long Island.

The great Brooklyn bridge (see BROOKLYN) carries huge crowds daily by means of its electric roads, and perhaps the greatest daily jam to be seen anywhere is at the New York entrance to the bridge from five to seven o'clock in the evening. A new East river bridge is now under construction, from the foot of Broadway, Brooklyn, to the foot of Delancey slip, Manhattan. It is proposed that this bridge shall be 118 feet wide, and 135 feet high for 400 feet at the middle of span at high water and lowest position of bridge, and will furnish accommodations for four surface railroad tracks, two tracks for elevated trains, two roadways for vehicles, two footways for pedestrians, and two cycle paths. The towers will be made of steel. The estimated cost is $8,000,000, exclusive of the right of way.

There are also many steam ferry boats on both East and North rivers. Two other large bridges, besides many smaller ones, span the Harlem; High bridge, which carries the Croton aqueduct, and the beautiful Washington carriage bridge.

BROOKLYN, which before its consolidation with New York, ranked as the fourth city in the United States, lies on the west end of Long Island, on the East river. The borough now occupies an area of 77.62 square miles, and has a water frontage of 33 miles. Besides numerous lines of ferries, it is joined to Manhattan by the magnificent Brooklyn suspension bridge, 5,989 feet in length by 85 in breadth, and with a river span of 1,595½ feet, intended for foot passage, carriages, and railways. The bridge was opened to surface lines Dec. 31, 1897, and it is estimated that about 100,000 trolley cars now cross the structure each month. It is the largest suspension bridge in the world, and its cost was about $15,000,000. A large number of railroads also connect the city with different parts of Long island, and a fine system of surface and elevated railways secures connection between different parts of the city. Some of its docks are the largest works of the kind in the country, covering from forty to sixty acres each. The Brooklyn United States navy yard comprises 144 acres, situated on a little bay in the East river, known as Wallabout channel, and has a water front of nearly three miles. In 1815, the *Fulton*, the first steam war vessel, was built at the yard after plans prepared by Robert Fulton. The first dry dock was begun in 1841, and completed ten years later at a cost of about $2,000,000. It is estimated that the government has spent over one billion dollars in this yard, and the property now there is valued at over $50,000,000.

In newspapers, theatres, educational institutions, etc., Brooklyn is well supplied, like all modern cities. The great Music hall is one of its finest buildings. It is the "city of churches," having hundreds of beautiful church buildings. Greenwood cemetery is one of the most beautiful burial grounds in the world. Its area of 400 acres contains many fine monuments. Prospect park, with an area of 540 acres, with its fine ocean views, is unsurpassed. The town was settled in 1636 under the Dutch, and was incorporated as a city in 1834.

The executive power of the city of New York is vested in the mayor and the officers of departments. The mayor is the chief executive officer, and he is a magistrate. The salary of the office is $15,000 a year.

The mayor appoints the heads of all departments save that of finance, and within six months after taking office he can remove any public officer appointed by the mayor, except members of the board of education and school boards, and certain judicial officers.

The legislative power of the city is vested in two houses, known respectively as the council and the board of aldermen, and together styled "The Municipal Assembly of the City of New York." The council consists of 29 members, one of whom is the president, and who is chosen for that office by the people. Of the other 28 members, three are chosen from each of the five council districts into which the boroughs of Manhattan and the Bronx are divided; three from each of the three districts in the borough of Brooklyn; two from the borough of Queens, and two from the borough of Richmond. Their terms are for four years. The board of aldermen consists of one member elected from each of the 60 assembly districts in the entire city for a term of two years.

The police force of the city numbers 7,614 men. The strength of the fire department is, regular force, 2,451; volunteer force, 3,725; total, 6,176. The net bonded debt of the city is $272,398,500; annual expenditure, $98,100,413; assessed value of property, real, $3,168,547,700; personal, $485,594,573. The various parks of the city contain a total of 6,962 acres. Of these the finest are Central Park, Manhattan, and Prospect Park in Brooklyn. Some of the others which are extensive in area, are as yet unimproved. The cemeteries contain 3,155 acres. There are 1,738 miles of paved streets; 353 miles of water front; 1,507 miles of sewers; and 785 miles of street railway, including elevated roads.

The water supply of Manhattan is received from the Croton watershed, thirty miles north of the borough. The capacity of the aqueducts and reservoirs is 380,000,000 gallons per day. The water supply of Brooklyn is obtained from the streams that drain the portion of the southern slope of Long Island lying to the west of Amityville, supplemented by wells driven into the saturated sand at different points in the same territory. From these streams and wells the water is delivered into iron pipes or brick conduits, which conduct it to the main pumping station at Ridgewood. Here it is raised to the Ridgewood reservoirs, having a capacity of about 300,000,000 gallons, and from them is passed into the distributing mains supplying the greater part of Brooklyn. The other boroughs are supplied by local plants, some of which are owned by the city and others by private corporations. There are in the city more than 2,000 miles of water mains.

The number of pupils in the public schools of the city is 443,072; the number of principals and teachers employed is 11,070. The college of the city of New York and the Normal school are the highest schools of the public system, and are free. Of higher institutions of learning here located, the more important are Columbia university, with 339 instructors, and New York university, with 175 instructors.

There are three divinity schools, Union Theological seminary (Presbyterian), the General Theological seminary (Episcopalian), and the Jewish Theological seminary. Of more than one hundred general and special libraries in the city, the more important are, New York Public library, formed by the consolidation, in 1895, of the Astor and Lenox libraries and the Tilden fund, and containing 500,000 volumes; Columbia university library, 295,000 volumes; Mercantile, 263,000 volumes, and Brooklyn, 150,000 volumes. The museum of art and museum of natural history are in Central Park.

The following table gives the population of the city and of the different boroughs: —

Boroughs.	Population Census of 1900.	Area in Acres.	Area in Sq. Miles.
Manhattan	1,850,093	14,038	21.93
Brooklyn	1,166,582	49,680	77.62
Bronx	200,507	26,017	40.65
Queens	152,999	82,883	129.51
Richmond	67,021	36,600	57.19
Total	3,437,202	209,218	326.90

New Zealand lies in the Pacific ocean about 1,200 miles to the southeastward of the Australian continent. It is a British crown colony, with a local government extending back to the year 1852. There are two principal islands, known as the north and middle islands, besides the south or Stewart island and some small outlying islets. The total area is estimated at 104,471 square miles, with a population, in 1896, of 703,360, exclusive of aborigines which are chiefly Maoris (probably 50,000 in number). The chief town is Auckland, with a population, including suburbs, of 57,616. Wellington is the seat of government (population 41,758). The other towns of note are Christchurch (population 51,330), and Dunedin (population 47,280). Of volcanic origin, New Zealand has chains of high mountains, hot geyser springs, and other natural features of a bold and varied character, incident to its eruptive origin. It has a temperate climate favorable to the growth of rich succulent grasses and the rearing of sheep and cattle. Its area under crop exceeded, in 1899, 12,000,000 acres, while 20,000,000 acres were still under forest, and 9,000,000 acres of barren mountain tops, lakes, and worthless country. Large amounts of capital are invested not only in agricultural and mining operation, but in the meat-freezing and preserving industries, and in tanning, wool scouring, and in factories for making butter and cheese. Besides the wool crop and the farm and dairy products, there is a large annual export of tallow, hides, skins, and leather, together with gold, valued at $5,000,000 for the

yearly output. There are two houses of parliament, the members of both of which are paid. In the popular chamber, four Maori members sit, representing native districts under the Maori Representative Act. There is no state church in the colony, nor state aid given in any form to religion. The school system is administered by an educational department of the government under a minister, assisted by education boards and school committees. The University of New Zealand is solely an examining body, it awards scholarships to be held by students at affiliated colleges. There are four of the latter, viz., Otago university at Dunedin, with nine professors; Canterbury college at Christchurch, with six professors; Auckland university college, with four professors; and Victoria college, Wellington, with four professors, besides lecturers at each. They are all endowed with land, and in 1899 had 766 students in attendance. Most of the railways in the colony belong to the state and yield a good annual revenue; the gross mileage in both islands is 2,271 miles. In the chief towns there are tramways worked by cables, steam motors, or by horses. In common with Australia and Tasmania, New Zealand, in 1899, offered a military force to the imperial government for service in South Africa.

New'ark, the county seat of Essex county, N. J., and a port of entry, lies on the Passaic river, nine miles from New York. It is a handsome city, with small parks and wide, shaded streets. It has a city hall, court house, public library, and many churches, but its main feature is the 400 or more manufactories of brass and iron ware, hardware, machinery, trunks, saddlery, boots and shoes, hats, etc. The city was settled by a Connecticut colony in 1666 and chartered as a city in 1836. Population 246,070.

New'ark, the county seat of Licking county, O., lies on the Licking river, 31 miles northeast of Columbus. It is a manufacturing city, turning out stoves, machinery, furnaces, wagons, boilers, flour, woolens, and glassware. Population 18,157.

New'berry, Prof. **John Strong,** an American scientist, was born at Windsor, Conn., Dec. 22, 1822, educated at Western Reserve college, Hudson, O., and Cleveland Medical college, graduating from the latter in 1848. Practicing medicine in Cleveland a few years, he accepted an appointment in 1855 as surgeon and geologist to accompany the United States exploring expedition sent out to examine the country between San Francisco and the Columbia river. In the year 1857 he explored the cañon of the Colorado, devoting nearly a year to the task. In 1859, he made trips in the interests of science through southern Colorado, Utah, northern Arizona, and New Mexico. During the Civil war he was in charge of all the operations of the United States Sanitary Commission throughout the Mississippi valley. At the close of the war, he was appointed professor of geology in the School of Mines, Columbia college, New York. In 1869, he superintended the geological survey of the state of Ohio. He was elected a member of nearly all the scientific associations of his own country and of Europe, and received the Murchison medal from the Geological society of London in 1888. Perhaps his first publication was his report upon *The Geology, Botany, and Zoology of Northern California and Oregon;* and his latest was *The Paleozoic Fishes of North America.* He died at New Haven, Conn., Dec. 7, 1892.

New'berry, Walter Loomis, an American merchant and philanthropist, was born at East Windsor, Conn., Sept. 18, 1804. He removed to Chicago in 1833, where he amassed a fortune in trade and banking. He left over $2,000,000 with which to erect and maintain a library. The building which was a result of this bequest fronts upon Washington Common, Chicago, and is one of the architectural ornaments of the city. The library it contains is one of the finest reference libraries in America. Mr. Newberry died at sea, Nov. 6, 1868.

New'burg, the capital of Orange county, N. Y., lies on the left bank of the Hudson, in the beautiful Highlands. It has foundries, boiler works, shipyards, powder mills, and manufactures flour, woolen and cotton goods, leather, soap, brushes, paints, etc., and ships large quantities of butter, grain, flour, and coal. In the Revolutionary war, the American army disbanded here on June 23, 1783. Population 24,943.

New'buryport, a city and port of entry of Massachusetts, on the south bank of the Merrimac river, three miles from its mouth, and 37 miles by rail northeast of Boston. A long, shady, high street, with a pond of six acres, is its chief ornament. Shipbuilding is carried on, and there are a number of large cotton and shoe factories, besides manufactories of combs, hats, pumps, etc. Here George Whitefield, who died in 1770, is buried, and here Wm. Lloyd Garrison was born. Population 14,478.

New'castle-upon-Tyne', a city and county by itself, lies upon the river Tyne, in Northumberland, 117 miles from Edinburgh. During the Roman occupation of Britain, it was a military station, and afterward became a monastic settlement, and was known as Monkchester. In 1080, Robert Curthose constructed a fort which he called Newcastle. The city is built mostly on slopes and rising ground, and shows the combined effects of ancient and modern architecture. Some of the interesting buildings are the Norman Keep, the Black Gate, the St. Nicholas cathedral, and the churches of St. John and St. Andrew. The central part of the town owes its beauty and stability to Robert Grainger,

who developed and built it up. Newcastle has a large public library, two colleges, the Royal Infirmary, Jesus' Hospital, the Keelmen's Hospital. Its principal manufactures are marine and locomotive engines, machinery, heavy ordnance, carriages and harness, lead, glass, earthenware, cement, brick, tile. It has been since the 13th century the most important coal-shipping center in Europe. Population 230,000. See *Histories of the Town*, by J. R. Boyle, and others.

New'comb, Simon, a distinguished mathematical astronomer, born at Wallace, Nova Scotia, March 12, 1835. Coming to the United States in 1853, he secured, through the influence of Joseph Henry, an appointment as computer on the *Nautical Almanac* in 1857. He graduated from the Lawrence Scientific school at Cambridge in 1858, and spent three years there as a graduate student, at the end of which time he went to the Naval Observatory in Washington as professor of mathematics in the United States navy. His work here in connection with the establishment of the 26-inch equatorial, the various expeditions to observe transits of Venus and solar eclipses, his superintendence of the *Nautical Almanac*, and his important memoirs on celestial dynamics, have placed him in the front rank of astronomers. In 1884, he accepted the chair of mathematics at Johns Hopkins university while retaining his work in Washington. Professor Newcomb is a man of extraordinarily wide interests and has thought and written much on subjects outside of his own specialty, particularly on political economy. It goes without saying that he has been the recipient of many honorary degrees besides medals and honorary memberships from learned societies.

New'ell, Harriet Atwood, was born at Haverhill, Mass., Oct. 10, 1793. At the age of nineteen she was married to Samuel Newell, and with him sailed for India, February, 1812, in company with Dr. Judson, to open a mission there. When they arrived at Calcutta the Bengal government refused to admit them into the city. Ordered to leave the country, they sailed for the isle of France, where Mrs. Newell died, Nov. 30, 1812. She was one of the first lady missionaries to go out from the United States. Though she died on the threshold of her chosen career, her sublime devotion has inspired thousands of her sisters to imitate her example. Her memoirs by her husband, with her letters, have been translated into several languages.

Newfound'land, an island colony of Great Britain, in North America, lies at the mouth of the St. Lawrence. It is not incorporated with the Canadian Dominion. It is three-cornered in shape, has a length of 370 miles, a breadth of 290, and an area of 42,200 square miles. Although the surface looks barren and broken, the soil is good, and good crops of potatoes, hay, grain, etc., have been raised of late years. The coast is indented by numerous bays and estuaries, which afford excellent harbors. Its waters abound with fish, and most of the people are engaged in the fishing industry. There is good caribou shooting on the island and excellent sport for fishermen. The seal trade is still large. Almost one-third of the surface of Newfoundland is covered by fresh-water lakes and small winding rivers. Copper is extensively mined, and rich deposits of lead, iron, coal, and nickel have been found. The fisheries of cod, seal, herring, and lobster, together with the canning business, are very valuable.

Newfoundland was discovered June 24, 1497, by John Cabot, and visited by Gaspar de Cortereal in 1500, and two years later permanent fishing colonies were established by Biscayans, Portuguese, and French. England came into possession of the island from the French by the treaty of Utrecht in 1713. Newfoundland was under the exclusive control of an English government from 1728 to 1855, when the form was modified by adding a cabinet, legislative council, and general assembly. The island politics are disturbed at times by the claims of French fishermen and the French fleet, who visit the coast annually, and assert fishing rights to the detriment of the islanders, basing their claims on French possession of the islands of St. Pierre and Miquelon. Population (estimated, 1901) 210,000. The capital is St. John's (population 30,000). The other chief towns are Harbour Grace, Carbonear, and Bonavista. Dependent on Newfoundland is Labrador, with an area of 120,000 square miles, and a population of 4,200.

New'gate, a famous London prison, stands opposite the Old Bailey, at the end of Newgate street. Its high, windowless walls for a long time inclosed the principal prison of the city, but it is now under the control of the court of aldermen. It derives its name from having been the *new gate* to the city prior to 1218. The prison was destroyed by the fire in 1666 and rebuilt in 1780. Newgate was discontinued as a prison by the prisons bill of 1877. See Griffith's *Chronicles of Newgate.*

New'man, John Henry, Cardinal, a leader of the Church of England, afterward, in 1845, a communicant of the Catholic church, and in 1879 a cardinal by appointment of Leo XIII., was born at London, Feb. 21, 1801, and graduated from Trinity college in 1820. In 1822, Newman was elected a fellow of Oriel college, and there formed the intimacy with Pusey and Froude which exerted such an influence on his after-life. In 1832, he published his first book, called the *Arians of the Fourth Century*, in which he vindicated the divine nature of Christ, and laid down the dogmatic definition of the Son as being "of one substance" as the Father, not "of like substance." In 1833, he traveled to the

Mediterranean with Froude and his father for his health, and on the journey wrote most of the poems which were afterward published as *Lyra Apostolica*, the object being to assert the spiritual power of the Church of England. On his return to England, he entered with all his energies into the Tractarian movement in the Anglican church. He wrote a great many of these tracts himself, defined a line between Protestantism and Roman Catholicism, and delivered courses of lectures on that subject, teaching that the Anglican church stands midway between the Catholic and popular Protestant. His most notable book is the *Apologia pro vita sua* (a history of his religious opinions). On Oct. 9, 1845, he entered the Roman Catholic church. As a Catholic, his works are, mainly, *Loss and Gain*, a story of a conversion; *Callista*, the story of an African martyr; *Grammar of Assent;* a volume of lectures on *Anglican Difficulties*, a collection of *Verses on Various Occasions;* and several volumes of sermons. To reward and conciliate the English moderators, of whom Newman was the head, Leo XIII. made him a cardinal on May 12, 1879. He died at Edgbaston (Birmingham), Aug. 11, 1890, of pneumonia.

New'port is the county seat of Campbell county, Ky., lying opposite Cincinnati, on the Ohio, at the mouth of the Licking river. The city has large rolling mills, foundry, bolt works, steam mills, and tile works. Population 28,301.

New'port, a city of Rhode Island, is a port of entry, and was formerly one of the capitals of the state. It contains a courthouse, statehouse, library, and many summer homes and villas, and is one of the most fashionable watering places in the United States. The Round Tower, or "Old Stone Mill," stands in Touro Park. Cotton mills, lead and oil works, and a brass foundry are among the industries of the city. The town was settled in 1638 by eighteen followers of Roger Williams. Population 22,034.

New'port News, Va., a rapidly growing town, and port of entry, on the James river, Hampton Roads, southeastern Virginia. It is the capital of Warwick county, is connected by electric railway with Hampton and Old Point Comfort, and is fourteen miles north of Norfolk, and seventy miles southeast of Richmond. Possessing a magnificent harbor, it has extensive ship-building plants, dry docks, grain elevators, and capacious warehouses on its piers. It has a large foreign commerce, chiefly of grain. It has a large trade in peanuts. Population 19,635.

New Rochelle (*rō-shĕl'*), **N. Y.,** a town in Westchester county on an inlet of Long Island Sound, and on the New York, New Haven, and Hartford railroad. Being within twenty miles northeast of New York city, many merchants of the great capital make their homes here, and find it a salubrious and attractive resort. It possesses good schools, churches, banks, and other adjuncts of a growing suburban city and watering place. Population 14,720.

News'paper, a sheet of paper printed and distributed from time to time for the purpose of conveying news. The number of newspapers now in the world is estimated at about 45,000. The bulk is issued as follows: United States, 20,000; Germany, 5,500; France, 4,100; Great Britain and Ireland, 2,385, besides 2,290 magazines and reviews; Austria-Hungary, 3,500; Italy, 1,400; Spain, 850; Russia, 800; Switzerland, 450; Belgium and Holland, 300 each, and Japan, 200. Of the languages in which they are published, 17,000 are printed in English; 7,500 in German; 6,800 in French; 1,800 in Spanish, and 1,500 in Italian. Newspapers first came into existence when the reports of the Roman imperial army were transmitted to the generals in all parts of the country, but for the actual newspaper we are indebted to Germany, where in Augsburg, Vienna, Ratisbon, and Nuremburg, it was, early in the 15th century, the practice to issue news sheets in the form of letters. Yet the first newspaper that at all covered the same idea as those of the present day, was issued in Venice, by order of the Venetian government in 1566, and called the *Notizie Scritte*. At first they were not printed, but written out, and hung up in various public places, where the people could read them on payment of a small coin. The first actual English newspaper was the *Weekly News* of 1622, edited and published by Nathaniel Butler. The London *Weekly Courant* came out in the same year. The first daily paper was the *Daily Courant*, which appeared printed on one side only, in 1702. To-day (1901), the daily circulation of newspapers in the United Kingdom reaches 8,500,000. The regular system of advertising, which now supports the newspaper, and benefits the advertiser, did not begin until 1673, when the columns of a few papers were opened to regular classified advertisements. Some of the principal and largest newspapers of to-day are: In England, the (daily) *Times*, *Daily Mail*, *Telegraph*, *Standard*, *Star*, *Echo*, *Evening News*, and *Post;* in France, *Temps*, *Figaro*, *Siècle*, *Petit Parisien*, and *Le Petit Journal*.

There are now published in the United States over 20,000 newspapers, of which about 2,100 appear daily. The first newspaper published in America was *Publick Occurrences* (1690), followed in 1704 by the *Boston News-Letter* and the *Boston Gazette*. At the present time a newspaper is not only a sheet for disseminating news, but is apparently a leader in politics, a commentator on the same, on religion, research, science, amusement and sport, and social and political economy. See Baker's *The Newspaper World*.

Newt, a common salamander, represented by several distinct species, abundant in quiet waters of the United States and Europe. It is also called eft and triton. The common newt of the eastern United States (*diemictylus*) is about three and one-half inches long and is shaped like a slender lizard. It varies in color, but is commonly pale greenish above and pale yellowish below with small black specks. A variety of the common water newt is reddish with red spots and is found in damp places in the woods. The newts feed on insects, larvæ, snails, and the like. One in California reaches a length of six inches. See Gage's *Life-History of the Vermillion-spotted Newt, Amer. Naturalist,* December, 1891.

New'ton, a city of Massachusetts, about seven miles from Boston, and almost surrounded by the Charles river. It is used as a suburban residence by many Boston people, and manufactures cloth, silk, shoddy, glue, etc. Population 33,587.

New'ton, Sir Isaac, the foremost English expounder of applied mathematics. As a natural philosopher he stands without a peer, unless, perhaps, Helmholtz is to be admitted to this category. To save space we shall first outline his chronology and then his achievements. He was born at Woolsthorpe in Lincolnshire on Christmas day, 1642 (old style). He early showed an inventive and mechanical genius, preferring to make windmills, kites, etc., rather than to indulge in the ordinary play of children. His uncle, a Mr. Ayscough, persuaded his mother to send him to Cambridge university, where he entered Trinity college June 5, 1661. In January, 1665, he graduated bachelor of arts; was elected fellow of Trinity in 1667; and graduated master of arts, in 1668. In October of the following year he was elected Lucasian professor of mathematics at Cambridge. His election as fellow of the Royal society occurred Jan. 11, 1672. The publication of his immortal volume, the *Principia*, marks the year 1687 as the beginning of a new era. In four years (1692) this work was practically out of print; and it was not until 1713 that a second edition appeared. Newton began a new rôle in 1689 as representative of Cambridge university in parliament. In 1703, was conferred upon him the highest honor in science to which an Englishman can aspire, namely, the presidency of the Royal society. Only two years elapsed until the order of knighthood was made illustrious by being conferred upon him. The year 1697 marks his departure from Cambridge and his appointment as master of the mint, an important public office which he filled with distinction until his death, which occurred in 1727.

So much for the mere times and places associated with Newton's life. Passing now to the work of the man, we find it so profoundly influencing, and so thoroughly interwoven with the entire subsequent history of physical science as to make a summary of his achievements well nigh impossible.

1. Among his earlier studies must be mentioned the brilliant series of optical experiments by which he proved white light to be composed of many simple colors, and by which he explained the color of natural bodies. Among many other important contributions to optics may be mentioned his accurate description of the phenomena of diffraction, the cause of colors exhibited by thin plates, and a measurement of the wave-length of light, though in terms of the corpuscular theory.

2. Of that branch of astronomy which is known as Celestial Mechanics, Newton is practically the creator. Having clearly formulated the fundamental principles of dynamics, he proceeded to ask whether the facts described by Kepler's Laws (see KEPLER) could not be expressed in a still simpler manner. The answer to this question is found in the *Principia*, where he shows that all the celestial motions are mere consequences of the one general law of gravitation, namely, that the force of attraction between any two particles varies directly as the product of their masses and inversely as the square of their distances. This law was first tested by applying it to the moon's motion about the earth; and the attraction of the earth, on this basis, was found exactly to account for the behavior of the moon. In this connection every student should be warned against the popular notion that Newton discovered the explanation of gravitation. Nothing could be further from the truth. Indeed Newton himself expressly disclaims any such thing; and insists that, while he has succeeded in describing some of the phenomena of gravitation, he will not even venture a guess as to the cause of gravitation. It need hardly be added that we are to-day apparently as far from any satisfactory explanation of gravitation as in the days of Newton.

3. In mathematics, his genius is perhaps best shown by the fact that he not only discovered the law of gravitation, but invented the differential calculus by which to discuss the facts involved. But just how the honors for the discovery of this powerful means of investigating mathematical problems are to be shared between Newton and Leibnitz is a question which has perhaps not even yet been satisfactorily answered. See Brewster's *Life of Newton.*

New'ton, John, an English divine and religious poet, and a friend of Cowper, was born at London, July 24, 1725, and at eleven years of age joined his father on shipboard for six years. He was then impressed into the navy, and from there exchanged to an African cruiser, and then on a slave trader, where he remained for two years before returning to England in 1747. He renounced sailing in 1755, and in 1758 applied for holy orders, but was refused. He was then offered

the curacy of Olney, where, four years later, he formed the friendship of the poet Cowper. Newton was a pronounced Calvinist. He left Olney to become rector of St. Mary Woolnorth in London, where he died Dec. 21, 1807. His prose works are little read, but his *Olney Hymns* are still used and fresh in the memory of all. See *Life*, by Richard Cecil.

New'ton, General **John,** an American engineer and soldier, was born at Norfolk, Va., Aug. 24, 1823, and graduated at West Point in 1842. His first professional services were rendered as assistant instructor in engineering at the Military academy, whence he was transferred to Utah as chief engineer of the expedition sent in 1857 to Salt Lake. At the outbreak of the Civil war he was engaged in the construction of fortifications along the Atlantic and Gulf coasts. When the safety of Washington was threatened in 1861, he was put in command of the defenses, and given the rank of brigadier-general of volunteers. Having served throughout the Peninsular campaign as brigadier, at Fredericksburg he commanded a division and rose to the rank of major-general. He rendered conspicuous services at Chancellorsville and further distinguished himself at Gettysburg. He was thereupon sent to assist Sherman, and he arrived in time to take part in the capture of Atlanta. At the close of the war, he returned to the work of the engineer corps of the regular army with the rank of lieutenant-colonel. His greatest work of engineering was the removal of the obstruction called Hell Gate in the East river, New York. After this he was given the position of chief of the engineering department with the rank of brigadier in the regular army. He retired from the service in August, 1886, and was elected president of the Panama Railroad company in 1888. He died at New York, May 1, 1895.

Ney (*nā*), **Michael,** one of the famous marshals under Napoleon, was a cooper's son, born at Saarlouis, Jan. 10, 1769. At the beginning of the revolution he was an under-officer in a hussar regiment, but merit soon brought him promotion, and after the siege of Mainz, in 1794, he was made adjutant-general. He earned the rank of brigadier-general under Jourdan, in 1796, and for the capture of Mannheim, in 1799, was made general of division. He was also at one time commander of the army of the Rhine, and after the declaration he married a friend of Napoleon and was made inspector-general of cavalry. When the empire was established he was made marshal of France. He stormed Elchingen, and for this was created duke of Elchingen. At Jena and Eylau he served with distinction, as well as in Spain and in Russia. At Waterloo, he led the center and had five horses shot under him, but after the surrender of Paris, in flight to Switzerland, he was recognized by a costly sword he wore, and condemned by the house of peers to die for high treason, in going over to Napoleon on his return from Elba. He was shot in the Luxembourg gardens, Paris, Dec. 7, 1815.

Nez Perces (*nā' pĕr'sĕz'*), meaning "pierced nose," a tribe of American Indians that settled in Idaho, and were friendly to the whites. In 1877, some refused to accede to a treaty reducing their reservation, and attacked the settlers and soldiers, and then fled to Montana and Dakota. They were overtaken, and the 350 survivors transferred to the Indian Territory, and in 1885 were sent to Idaho, and some to join the Colville Indians in Washington.

Ngami (*ng a'mē*), **Lake,** discovered by Livingstone in 1849, is situated in the northern extremity of the Kalahari desert, in British South Africa, is 2,810 feet above sea level. Its size depends on the rainfall in the surrounding country, but its average length is 50 miles, and width from 10 to 20. Its chief tributaries are the Okovango on the northwest, and the Zouga on the east.

Niag'ara ("Thunder of Waters"), a river of North America, which forms part of the boundary between New York state and the province of Ontario. It flows from Lake Erie into Lake Ontario, a course of 36 miles, during which it makes a total descent of 326 feet, about 50 feet in the rapids immediately above the great falls, and nearly 110 feet in the seven miles of rapids below. It incloses several islands, the largest, Grand island, being nearly 10 miles long. Four miles below this island, are the most famous falls in the world. The center of the river here is occupied by Goat island, dividing the cataract into two, the Horseshoe (Canadian) Fall, with a descent of 158 feet, and the American Fall, 162 to 169 feet; the outline of the former is about 2,640 feet, of the latter 1,000 feet. The volume of water which sweeps over this immense chasm is about 15,000,000 cubic feet a minute. The depth of water on the crest of the falls is less than four feet, except in a few places, notably at the apex of the Horseshoe Fall, where it is about 20 feet. The limestone edge of both falls is rapidly wearing away in the center. For seven miles below the falls, the river is shut in between perpendicular walls of rock, from 200 to 350 feet high. Just below the cataract, the river is crossed by a suspension bridge for carriages and foot-passengers, and a mile and a half further down there are two railroad bridges, one a cantilever bridge, about 100 yards apart. On both shores the lands bordering the river, for some distance above and below the falls, are under the immediate control of the respective governments. The "New York State Park at Niagara Falls" embraces 115 acres, and the "Queen Victoria Niagara Falls Park" about 154 acres. From both sides visitors clad in waterproofs are conducted under the Falls. The immense water-power supplied

by the Falls was utilized at Buffalo by the Pan-American exposition, in 1901, in its electric displays.

Niag'ara Falls City, N. Y., a rapidly growing town in Niagara county, on the Niagara river, the mecca of every visitor to the New World, for the incomparable beauty and majesty of the spectacle — the mighty Falls of Niagara, — which here hurl their mass of waters, by the American Fall and the Horseshoe Fall, over into a narrow seething gorge, a chute of 160 feet. The situation of the city and the famous cataract is 20 miles north of Buffalo, and about 13 miles south of Lake Ontario, with whose waters the Niagara river mingles. A number of railway lines here converge, viz., The New York Central; the Erie; the Lehigh Valley; and the Michigan Central railroads. All of them have their connections into Canada, which is entered from New York state by a series of bridges, cantilever and suspension; there is also across the chasm a foot and carriage bridge, and connecting links between the city and Goat island; also state reservations in the immediate neighborhood of the cataract. Of recent years, engineering skill has, by a series of tunnels and the construction of a hydraulic canal, utilized for practical industrial purposes the enormous water-power here obtainable, — a utility which the city of Buffalo has taken advantage of. Population 19,457.

Niag'ara Falls, Tunnels and Power Plant. The force going to waste over the Falls of Niagara has been estimated at 7,000,000 horse-power. Such unused resources naturally attracted the attention of engineers and economists at an early day, and in 1873 a small canal utilized about 6,000 horse-power for certain mills. The invention of the dynamo and the transmission of energy by electric wire gave a new impulse to the attempt to use more of the power in sight. A company was organized in 1886, and chartered by the legislature of New York, having this end in view. Experts visited Europe to study approved methods of power transmission. Work was begun in 1890 by the Cataract Construction company, and a tunnel was dug, 7,000 feet long, 21 feet high, and 19 wide. It required three years time and the outlay of about $4,000,000 to carry the undertaking to completion. The water is drawn from the river by means of a canal 110 feet wide at the end and 180 feet at the mouth, the canal being 1,400 feet long. The water, which is brought from the river by the canal, is carried over the turbine wheels, 14 in number, each having 5,000 horse-power; and, after passing through the turbines, it is carried away by the tunnel. Each turbine is connected with a dynamo of 5,000 horse-power, and the electric current is thus brought to Buffalo, 18 miles distant, where it is used for lighting the city, operating tramways in the streets, pumping water for city use, and running machinery in various factories. It is expected that the power thus generated will be distributed over all the western part of the state by improved processes of transmission.

Nibelungenlied (*nē'be-lōng-en-lēd*), a German epic, ranking as one of the greatest poems of the world. The oldest elements of the work must have been long current in the form of popular songs; but the incidents of the story seem to have been fused into one narrative before the 12th century, though by whom it was done is unknown. The story of the poem is as follows: "Siegfried, the son of the king of the Netherlands, becomes possessed of the fabled wealth of the Nibelungs, which carries with it evil to its possessor. He marries Kriemhild, the daughter of Gunther, king of Worms, and helps Gunther to win Brunhilde of Iceland. Then there is a dispute as to whether Siegfried or Gunther be the greater, and Brunhilde induces Hagan to murder Siegfried. Kriemhild, after some years, marries Attila, king of the Huns. After Kriemhild became possessor of the Niebelungen wealth, Hagan took it from her and sunk it in the Rhine and after several years Kriemhild, still mourning for Siegfried, and desiring to be revenged for his death, asked her brother to visit her at her court. This he did, with 11,000 armed Burgundians, and the remainder of the poem is devoted to the wars and sufferings of the Burgundians. See English translations by Lettsom, Foster, Barham, and Birch. See also Carlyle's *Miscellanies*, Vol. III.

Nicæa (*nī-sē'-ă*), a city of ancient Bithynia, in Asia Minor, lies on the east shore of Lake Ascania. It was built in 316 B. C. by Antigonus and named Antigoneia, but was changed to Nicæa by Lysimachus in honor of his wife. It is famed as the seat of two ecumenical councils, the first held by Emperor Constantine in 325 A. D., and the second called by the Empress Irene, in 787.

Nicaragua (*nē-kă-rā'gwă*), an independent Central American republic, stretches across the isthmus from the Caribbean sea to the Pacific ocean, and lies between Honduras on the north and Costa Rica on the south. It has an area of about 49,200 square miles. The Central American Cordilleras extend through the country from northwest to southeast, not far from the Pacific coast. From these the surface sinks rapidly westward, and the country is studded with large lakes, the largest, Nicaragua, 115 miles long and 45 broad, and Managua, 35 miles long and 20 wide. This tableland is also marked by isolated peaks and volcanic cones, as Ometepec, Madera, Guanacaure, Viego, Telica, Momotombo, Mombacho, and others. On the west lie Managua the capital (population 25,000); Leon, Granada, Chinandega, and Rivas, and the harbors of gulf of Fonseca, Salinas bay, and Corinto, and on the east the harbor of

Greytown, on the San Juan river. The principal rivers are the Coco (350 miles), San Juan, Bluefields, and Rio Grande. Minerals are found in the republic, but only of late have they begun to be worked. In 1898, the shipment of gold dust amounted to 16,242 ounces. The rich soil yields corn, sugar, cocoa, cotton, rice, tobacco, and indigo, and the natural products, mahogany, rosewood, logwood, fustic, sandalwood, india rubber, dye woods, medicinal plants, and gums.

Nicaragua was the center of the civilization of the Aztecs, and the unknown race before them. Columbus sailed along the coast in 1502, and in 1524 the city of Granada was founded by Spaniards, who had entered two years before. From 1560 to 1821 the state was a dependency of Guatemala, but in that year became independent and so remained for sixteen years. Then until 1865 it had a troublesome and warlike time, but since then it has made great strides toward peace and prosperity. In 1894, a new constitution was proclaimed, which was amended in December, 1896. By this the legislative power is vested in a congress of one house. Population, including uncivilized Indians, 420,000. See Bancroft's *History of Pacific States.*

Nicara'gua Canal. The plan to cut a ship canal through central America by way of the San Juan river and Lake Nicaragua was taken up in earnest in 1884 and a treaty made between the United States and Nicaragua. The Nicaragua Canal company was formed in 1889 to work under plans made by A. G. Menocal, of the United States navy, giving the canal a total length of 170 miles, 121 miles of it being the free navigation of the river and lake. The canal was begun at Greytown, at the mouth of the San Juan river, in 1889, and it was expected that the work would be completed at a cost of $60,000,000. But after expending $4,000,000, the company found the burden greater than they had anticipated, and sought an appropriation from congress of $100,000,000, with provision for government supervision. Failing in this the work ceased, and finally the concession from the government of Nicaragua lapsed. In 1897, the United States government took up the question of the construction of a canal, and a commission was appointed to make surveys and report upon the most practicable route, and estimate the cost of constructing the canal. In 1899, a new commission was authorized to make further inquiry and report, considering both the Nicaragua route, and the Panama route. The Nicaragua route was recommended, and the cost of canal was estimated at from $118,000,000 to $135,000,000. In 1900, a treaty was negotiated between the United States and Great Britain, with the view of facilitating the construction of the canal, and removing the objections to it arising out of the historic Clayton-Bulwer treaty. This treaty failed of confirmation by the United States' senate, and a new treaty is now being considered.

Nich'olas I. was born of noble Roman parentage, and elected pope in 858 A. D. He was zealous in upholding the power of the Roman curia (court of justice). He died in 867.

Nich'olas I., emperor of Russia, third son of Paul I., was born at St. Petersburg, July 7, 1796; was carefully educated, and later devoted his time to military studies and political economy. He traveled over Europe, and after marrying the eldest daughter of Frederick Wilhelm III. of Prussia, and upon the resignation of his elder brother, Constantine, he ascended the throne in December, 1825. In 1828, the war with Persia began, and on its close occurred the war with Turkey. This was followed by the rising of Poland, which he subdued, and reduced the kingdom to a mere province. His rule now

Nice (*nēs*), a French seaport and the largest town of the Alpes-Maritimes department of France, lies on the coast 140 miles from Marseilles. Owing to its southern sea exposure and shelter by the hills on the north, it has long been a famous winter resort for invalids. The city is divided into three parts—the New Town, Old Town, and the Port. The chief public buildings are the cathedral, Church of Nôtre Dame, natural history museum, art gallery, library, observatory, and casino. Its main export is olive oil. The town was founded by a colony from Massalia and became subject to Rome in the 5th century B. C. It was once in the hands of the Saracens, and after being an independent city acknowledged the counts of Provence and the house of Savoy in 1388. In 1543, it was pillaged by the Turks, and in 1860 was finally ceded to France by Sardinia. In 1887, it was visited by a destructive earthquake. Population 93,760. See Nash's *Guide to Nice.*

became despotic and fierce. He remained inactive until the Austro-Hungarian rebellion in 1848–9, when he was called in to aid Austria. This strengthened him with the European powers and he began to think of absorbing Turkey. The opposition of the western powers led to the Crimean war, during which he died at St. Petersburg, March 2, 1855.

Nich'olas II., czar of Russia, born at St. Petersburg, May 18, 1868; succeeded to the throne Nov. 1, 1894, on the death of his father, Alexander III. He married Princess Alix, of Hesse-Darmstadt, granddaughter of the late Queen Victoria of England, Nov. 26, 1894. His reign has been marked by the construction of a railroad through Siberia to the Pacific coast, by adroit diplomacy with China, and by a strong and conservative attitude toward Turkey, as well as toward the European powers.

Nich'olas V., Pope of Rome, 1447–55, was born at Pisa, in 1398, and died in 1455. He was liberal to scholars and artists, and practically founded the Vatican library.

Nich'olas, St., the patron saint of Russia, whose life is wrapped in obscurity. He is supposed to have lived about 300 A. D. He was bishop of Myra, in Lycia, and was imprisoned under Diocletian and released under Constantine. In Catholic countries St. Nicholas is especially the patron of the young, and particularly of scholars. In England, his feast was publicly celebrated in ancient times. Santa Claus is a corruption of the name, introduced into England from America; the old Dutch settlers of New York kept a San Claus holiday. St. Nicholas was also the patron of merchants, sailors, and travelers; and as he was prayed to for protection against robbers, the term "clerks of St. Nicholas" came, oddly enough, to be a cant name for robbers.

Nicias (*nish'i-as*), an Athenian statesman and general of the Peloponnesian war, was the son of the wealthy Niceratus. After the death of Pericles, he was the political opponent of Cleon, and later of Alcibiades. In 427 B. C., he defeated the Spartans and Corinthians, and ravaged Minoa, Melos, and Locris. In 424, he ravaged Cythera and part of Laconia. In 415, he was appointed one of the commanders against Sicily, and in the autumn laid siege to Syracuse. At first successful, later his fleet was destroyed, his army began a retreat, and he was captured and put to death in 413 B. C. See Plutarch's *Life of Nikias* (edited by H. A. Holden).

Nick'el, a malleable, ductile, and tenacious grayish-white metal, was discovered by Cronsted, in 1751, but was long before that time used in alloys by the Chinese. Yet previous to 1879, it being difficult of fusing, was only used as an alloy in German silver. In that year Fleitmann discovered that mixed with ⅛ of one per cent. of magnesium it could be easily rolled and drawn. The metal does not readily alter by exposure, but it easily dissolves in nitric acid. It is now used as an alloy with copper and zinc in German silver and is largely used for plating articles of iron and steel. In some alloys it is used for coins. It is also extensively used in steel for armor plates, cannon, etc. The ore, in different forms, is found in Canada, Norway, Germany, Hungary, France, and in the United States.

Nic'otine. See POISONS.

Niebuhr (*nē'bör*), **Barthold Georg**, a distinguished modern historian, was born at Copenhagen, Aug. 27, 1776. After careful study at Kiel, he devoted himself to the study of natural sciences at London and Edinburgh. In 1800, he married and entered the Danish state service, from which he resigned in 1806, to enter the Prussian state service. From 1810 to 1812 he gave a course of lectures at the new University of Berlin on Roman history. From 1816 to 1823 he was German ambassador to the papal court. He died at Bonn, Prussia, Jan. 2, 1831. Some of his works are *Lectures on the History of Rome*, *Lectures on Ancient History*, and *History of Byzantium*.

Niemen (*nē'men*), a river in western Russia, rises a few miles south of the city of Minsk, divides into two branches below Tilsit, and empties into Kurisches Haff by four mouths to each branch. It is 500 miles long and navigable as far as Grodno.

Ni'ger, the name generally applied to a remarkable river system of west equatorial Africa, whose main features have as yet been but partially settled by exploration. It was thought to be a tributary of the Nile; then of the Congo, and then supposed to terminate in an inland basin; but the work of Mungo Park and others have settled all but 70 or 80 miles of its length. The Niger proper is 2,600 miles long and its drainage basin has an area of 1,023,280 square miles. The headwaters are in the present states of Samory, near the headwaters of the Senegal; but the Tembi, rising in the Loma mountains, 3,000 feet above the sea, is the actual source. From the source to Timbuktu, the river has only a few small tributaries, but some distance below here it is joined by the Benuë, or mother of waters, traveling 860 miles from the east. Thence the river flows to its mouth, where a beautiful delta is formed. The navigation is free, but the trade, chiefly in palm oil, is under the control of Great Britain. See Joseph Thomson's *Mungo Park, and the Niger*.

Niger'ia, Northern and Southern (formerly the Niger Territories, until Jan. 1, 1899, administered by the Royal Niger company, but now under the control of the British Crown, along with Lagos colony). Nigeria covers an area in western Africa roughly estimated at between 400,000 and 500,000 square miles, with a population placed at from 25 to 40

millions. For administrative purposes this vast region is divided into two governments, those of Northern and Southern Nigeria. They embrace the area once the Fula or Sokota empire, with the subordinate sultanates of Gandu, Kano, Bornu, Benin, Donga, etc., watered by the Niger and its tributaries. On the gulf of Guinea, the territories have a seaboard of about 120 miles in length, on which are the towns Akassa, at the mouth of the Niger, the British naval headquarters; Bonny, Wari, Old Calabar, and New Calabar. A military force is stationed in southern Nigeria, partly at Asaba, and partly at Akassa. The capital of Northern Nigeria remains for the present at Jeba, though it is designed to create a new one in the direction of Kano, eastward toward Bornu, in a healthier and higher region more suitable for Europeans. The chief products of Nigeria are rubber, gum, hides, ivory, palm oil, and palm kernels. Northern Nigeria is rich in agricultural resources, cotton being largely grown and now manufactured. Here are found the Hausa race, who carry on the internal trade by means of caravans in Central Sudan.

Night'hawk, an American insect-catching bird related to the whip-poor-will. It is quiet all day but flies at dusk and is often called the bull-bat. It is common in many parts of the United States from May to October, and may be seen at nightfall, high in the air, sailing back and forth in search of flying insects. It is about ten inches long, of a dark color mottled with gray, and can always be recognized from the white spot on each of the long wings.

Night'ingale, a bird famous on account of its brilliant song, which for quality and variety is not exceeded by that of any other bird. The song of the nightingale has been a theme of poets for ages. This bird belongs to the group of the Old World warblers and is not found in the new world. It lives in the dense undergrowth and warbles at all times of day as well as at night. It should be remembered that there are also other birds that sing at night. The bird is about the size of the hedge sparrow. It is dull brown above, lead shading into grayish below. It is of graceful form, but otherwise plain. The so-called Virginia nightingale is the cardinal bird.

NIGHTINGALE.

Night'ingale, Florence, an Englishwoman philanthropist, daughter of William Edward Nightingale, was born at Florence in May, 1820, and during the course of her study of science, mathematics, and classics, with her father, showed a great desire to lessen human suffering, so much so, that in 1844 she began a tour of Europe, looking into the condition of hospitals, and in 1851 entered upon a course of study as a trained nurse at Kaiserwerth on the Rhine. On Nov. 4, 1854, the year of the outbreak of the Crimean war, she arrived at Scutari with thirty trained nurses and took charge of the military hospitals until the close, in July, 1856. She then turned her attention to the improvement of the sanitary condition of the army, and wrote many books and papers on that and kindred subjects, among them *Notes on Nursing*, *Notes on Hospitals*, *Life or Death in India*, etc. She is the founder of St. Thomas' Home in London for the training of nurses, and the recipient of a cross from the late Queen Victoria, and a bracelet from the sultan of Turkey. Longfellow praised her in *Santa Filomena*.

Night'shade, the name of a plant possessing narcotic properties. It has a slender stem, pointed oval leaves, white clustered flowers, and small, rounded, black berries. It is found diffused over all the world, and its leaves have the property of putting to sleep, though losing it when boiled. The several kinds of nightshade are known by different names—the woody nightshade as "bittersweet," deadly nightshade as "belladonna," and enchanter's nightshade as "circæa."

Ni'hilist, now used as designating a Russian revolutionist. It was first so introduced by Turgenieff, who defined a nihilist as one who "bows before no authority of any kind, and accepts on faith no principle, whatever veneration surround it." The nihilist believes in no institution of government, progress, or art, unless it be by and for the benefit of the masses. The movement with which the nihilist is identified had its origin in 1860, when the proposed freeing of serfs was prevented by the influence of the serf-owners with the czar. From this time the peasants organized societies to force the adoption of a new constitution, and in their efforts resorted to violence repeatedly, going so far as to kill the czar Alexander II., March 13, 1881. For alleged crimes, previous to this, hundreds were sent to Siberia in exile, while for the murder of Alexander II., many were hanged and hundreds exiled. The present czar, Nicholas II., lives in considerable dread of the nihilists, and may be said, in some measure, to be a prisoner in his palace, as outbreaks of the nihilists are frequent. See *Russia and the Siberian Exiles*, by George Kennan.

Nikko (*nēk'kō*), one of the chief religious centers of Japan, is beautifully situated in the Nikko Zan ("Mountains of the Sun's Brightness"), about eighty miles northwest of Tokio. A Shinto temple seems to have existed at Nikko from time immemorial, and in 767 its first Buddhist temple was founded; but the main celebrity of the place is due to the sepul-

chres and sanctuaries of Iyeyasu and Iyemitsu, the first and third shoguns of the Tokugawa dynasty. Iyeyasu was buried here with amazing pomp in 1617. His tomb lies forty steps higher up the hills than the numerous magnificent temples and other structures which cluster around it. Above the tomb, the hill on which it stands is covered to the summit with trees of various tints, while below are a vast number of temples, shrines, pagodas, monuments and religious edifices of all kinds, to which thousands of pilgrims resort every year, and by whose gifts Nikko has been thus beautified, making it one of the most attractive spots in all Japan, in addition to being the great sanctuary of the Shinto cult.

Nile, a great river of Africa, the ancient Nilus, the longest river of the world, and the sacred river of the Egyptians. It has its source at the north end of Lake Victoria Nyanza, and pouring over the Ripon Falls, runs 300 miles to join Albert Nyanza, 20 miles from which it falls 120 feet into a deep gorge, and flows in a northerly direction into the Mediterranean. At 7½° N. latitude the channel is divided in two, only to join again at 9½°, to be called the White Nile, flowing thus to Khartum, where it is joined by the Blue Nile, 950 miles long. These augmented waters flow for 200 miles before they are joined by the Black Nile. Below Khartum the navigation is impeded and dangerous on account of six rapids. The Nile begins to rise in April and reaches the highest point in September, often causing disastrous floods. The ancients believed that the river rose in Morocco and flowed underground for several days' journey, rising to the south of Ethiopia, thence passing northward. The Emperor Nero first began the investigations of the source of the river by sending out two expeditions, but they were not completed in their present form until the explorations by Speke in 1858, by Baker and Schweinfurth in 1868–71, and by Stanley in 1875 and 1889. The total length of the Nile from Victoria Nyanza to the Mediterranean is 3,400 miles, although it is believed that the river actually draws its water as far as 250 miles to the south of Victoria. See the writings of the explorers named.

Nile, Battle of the, was fought Aug. 1, 1798, in the bay of Abukir, at the mouth of the Nile, 13 miles northeast of Alexandria. Nelson gained a great victory over the French fleet, which was not only defeated, but almost annihilated; the flagship of the Admiral De Brueys blew up, and only two ships escaped. In 1799, Napoleon defeated a Turkish army here, and in 1801 Sir Ralph Abercromby's British expedition landed in the face of the enemy, and here he met his death.

Nil'sson, Christine, a Swedish prima donna and operatic singer, was born near Wexio, Sweden, Aug. 3, 1843. A magistrate was impressed by her singing at a fair, in 1857, and sent her to Stockholm and Paris for a musical education. She appeared first in Paris in *La Traviata* in 1864, and in London in 1867, and was soon ranked among the foremost singers on the modern stage. In 1872, she married M. Rouzaud, and in 1887 the Count di Miranda.

Nimes (*nēm*), the capital of Gard, a French department, lies in the valley of the Cevennes. It has narrow, crooked streets, and its principal interest lies in the Roman remains; there being the Corinthian Maison Carrèe, now a museum; an amphitheatre seating 20,000; a mausoleum, baths, and two gates. The city is the seat of large manufactories of silk, cotton, carpets, shawls, wine, brandy, etc. Nimes was settled from Marseilles and became one of the great cities of Gaul. It was in the hands of the Visigoths (465), Franks (507), Saracens (725), then belonged to Aragon, but finally came into the possession of France in 1259 by the treaty of Corbeil. Population 74,601.

Nin'eveh, the famous capital of the Assyrian empire, called Ninâ on the monuments, now a mass of ruins called Kuyúnjik. Though the city appears to have been entirely destroyed in the fall of the empire, the name of Nineveh continued, even in the middle ages, to be applied to a site opposite Mosul, on the east bank of the Tigris, where artificial mounds and traces of an ancient city wall, gave evidence of fallen greatness. The walls inclose an irregular figure, stretching about two and one-half miles along the Tigris, which protected the city on the west. The greatest breadth is over a mile. The most elaborate defenses, such as outworks and moats, can still be traced on the southern half of the east side; for this part of the city was most open to attack. It was not until the excavations of Botta, in 1842, and of Layard, in 1845, that anything definite was learned of the life and history of Assyria from its monuments and library. Not only have the magnificent remains of Assyrian architecture and sculpture been laid bare, but accompanying cuneiform inscriptions throw much light on the history of the city and its buildings. The mound of Kuyúnjik covers the palaces of Sennacherib and Assur-banipal, that of Jonah, a second palace of Sennacherib, and one of Esarhaddon. Of other remains, the most striking is the gateway near the center of the north wall, consisting of two halls, 70 feet by 23, the entrance to which, toward the town, was flanked by colossal man-headed bulls and winged human figures. Nineveh proper was only one of a group of cities and royal residences whose ruins still mark the plain between the Tigris, the Great Záb, and the Kházir. Nineveh proper appears to have been the chief seat of empire. But when the book of Jonah speaks of Nineveh as a city of three days' journey,

it is plain that the name is applied to the whole group of cities between the Tigris and the Zâb. See works of Layard, Botta, Flandin, Schrader, and Keilinsch. See also *Assyrian Discoveries*, by George Smith.

Ning-Po' ("City of the Hospitable Waves"), a treaty port of the province of Che-Kiang, in China, lies 16 miles from the mouth of the Ning-Po river; is surrounded by a wall 25 feet in height and 16 in thickness. It is a free port, exporting sedge hats, green tea, mats, cuttlefish, silk goods and raw cotton, and importing opium, cotton and woolen goods, tin and iron, kerosene oil, sugar, tobacco, and indigo. Population 255,000.

Niobe (*nī'ō-bē*), according to Homer's story of mythology, was the daughter of Tantalus and wife of Amphion, king of Thebes, to whom she bore six sons and six daughters. She was proud of her children, and despised Latona, who had only two. For this, Latona caused her children to slay all Niobe's with arrows, and Niobe herself was turned into stone on Mount Sipylus, from which tears flowed all summer. A statue group of Niobe and her children was discovered in Rome in 1583.

Nip'igon, a lake, and also a river and a bay, through which river and bay the waters of the lake flow to Lake Superior from the north. The lake lies about 25 miles north of the northernmost part of Lake Superior. It is 70 miles long from north to south, and 45 miles wide from east to west. It is surrounded by lofty shores, abrupt and precipitous in many places. Its shores being indented by many bays measure, it is estimated, nearly 600 miles in extent. It lies about 800 feet above the level of Lake Superior. Its waters are fed by many mountain streams, and being very deep and cold it is celebrated for the excellence of its fish. Being thickly studded with islands, it has become a favorite resort for sportsmen and others from the northern United States. It is said to have in January a mean temperature of but seven degrees above zero, or that of Godthaab in Greenland, and in July the mean temperature of San Francisco. By some authorities the name is spelled Nepigon.

Nippur, a city of Babylonia, situated between the Tigris and the Euphrates rivers, in the neighborhood of 100 miles southeast from Bagdad, and about 50 miles from the site of ancient Babylon. The mound which covers the ruins of the ancient city was first made the object of study by Sir Austen Layard in 1851. The expedition sent out by the University of Pennsylvania began work upon this mound in February, 1889. The excavations so carried on revealed the site of a city of great importance, one of the chief commercial and military centers of the ancient east. Professors Petrie and Hilprecht hold that the lowest remains exhumed indicate a city built at least 7000 B.C., and possessed of a well-developed civilization. It is thus shown that Babylonia was old before Egyptian civilization had acquired its characteristic features. Written records discovered carried the date of documents further back than ever before. The Temple of Bel, whose site was exhumed in Nippur, held the same relation to that city and its surrounding country that the Holy House did centuries later to Jerusalem. The University of Pennsylvania possesses a large and important collection of relics brought from this site.

Ni'ter. See SALTPETER.

Ni'tric Acid (HNO_3), is one of the most important acids. It was formerly, and sometimes is still, called *aqua fortis*. It is prepared by distilling a mixture of saltpeter, usually the cheaper Chile variety (sodium nitrate), with sulphuric acid. The strongest nitric acid is about half again as heavy as water, and is an intensely corrosive liquid, which is colorless when pure, but is usually colored yellow by the presence of lower oxides of nitrogen. It fumes in the air, colors the skin yellow, producing painful burns, and dissolves, usually, or oxidizes, all the commoner metals except gold and platinum, with the violent expulsion of choking red fumes. Aluminum is dissolved but slowly by it, and in some instances the strong acid must be diluted with water before it will act upon a metal. Dilute nitric acid is generally less active the more water it contains. Strong nitric acid, mixed with sulphuric acid, acts upon cotton and glycerine to form the explosives, guncotton and nitroglycerin. Nitric acid is extensively used in chemical operations, particularly to dissolve metals and to oxidize substances. When the metals or their oxides or carbonates dissolve in this acid, salts called nitrates are produced. Mixed with hydrochloric acid, nitric acid forms *aqua regia* (royal water), which is capable of dissolving gold and other substances that are not attacked by a single acid. Nitric acid is also used to some extent in medicine. HORACE L. WELLS.

Ni'trogen is an elementary gas which in the free state forms nearly four-fifths by volume of our atmosphere. In combination with other elements, nitrogen is a necessary constituent of all plants and animals, and it forms a very large number of important compounds, both natural and artificial. Its presence in the atmosphere was discovered in 1772 by Rutherford, at that time professor of botany in the University of Edinburgh. It was more particularly, investigated soon after by Priestley, Scheele, Cavendish, and Lavoisier. It is a colorless, tasteless, odorless gas, and was formerly regarded as permanent and incondensable; but it can be liquefied at a sufficiently low temperature. Nitrogen is slightly lighter than atmospheric air, and is fourteen times as heavy as hydrogen. It is but slightly soluble in water, one hundred volumes of

water at ordinary temperature dissolving only one and a half volumes of nitrogen.

While nitrogen is a constituent of all plant and animal organisms and of many important compounds, it is, in a free state, rather inert toward other elements and does not readily enter into direct combination with them. It is not combustible, nor does it act in the atmosphere as a supporter of combustion, as a lighted taper plunged into a jar of nitrogen will be at once extinguished. Nitrogen is not poisonous, since it is breathed freely along with oxygen by all animals; but it cannot support life, and an animal placed in it will die from suffocation for want of the oxygen necessary for breathing. Its function in the atmosphere seems to be mainly that of diluting the oxygen with which it is there associated. Although nitrogen forms about 79.1 per cent. of the total volume, and 77 per cent. of the total weight of the atmosphere, the free gas cannot be taken up by plants directly, but it is combined with other elements through the agency of certain bacteria that exist in nodules on the roots of leguminous plants, that is, those that are related to clover, peas, etc. Other plants, particularly grasses and grains which require much nitrogen, are dependent upon the combined nitrogen of the soil; hence nitrogenous fertilizers such as dried blood, ammonium salts, and nitrates, as well as ordinary manures, are important in agriculture for use on soils containing insufficient nitrogen. Two of the important compounds of nitrogen are nitric acid and ammonia. This element is also an essential constituent of the proteids or albuminoids, which make an important part of our food, as well as of the alkaloids, most of the dyes, and a host of other natural and artificial compounds. H. L. WELLS.

Ni'troglyc'erin, a powerful explosive, is formed by dissolving glycerin in equal parts of nitric and sulphuric acids and pouring into water. The process was discovered in 1846 by an Italian chemist named Sobrero, but it was not used for blasting purposes until Nobel, a Swedish engineer, used it in 1861. The danger of explosion was so great in handling it that its mixture with powdered substances, especially dynamite, are now chiefly used. If lighted in the open air it will burn usually slowly without an explosion, but if given a hard blow or brought into contact with a red-hot iron it will explode. It begins to decompose at 150° to 180° F., and explodes at 450°, also if allowed to become solid at from 40° to 45° F.; a breaking of the crystals in this form may cause an explosion. It has thirteen times the power of the same bulk of gunpowder and eight times the power of the same weight. It is also used in solution for treating some diseases of the heart and stomach.

No'ah, the son of Lamech, and the tenth in descent from Adam. According to the Scripture narrative, he was the only righteous man in the world immediately prior to the flood. God therefore warned him of the coming deluge and gave him instructions for building the ark, which was to shelter all who survived it. While the ark grew under his hands, Noah tried to persuade his fellowmen to repentance, but in vain. When the ark was finished, he entered it with all his family and one pair of all kinds of animals. The flood came and all living things outside of the ark perished. After the rain ceased and the waters sank, the ark rested on Mount Ararat, in Armenia. Here Noah offered a sacrifice to the Lord, which was accepted, God making a covenant with Noah and confirming it with the sign of the rainbow in the clouds. The traditions of other nations coincide with the biblical history of this event. (See DELUGE.) Noah died at the age of nine hundred and fifty years.

Node, the distinct joint formed by stems from which the leaves and branches arise. The portions of the stem between the nodes are known as internodes.

Nor'dau, Max Simon, a Hungarian physician and author, was born at Budapest, July 29, 1849, of Jewish ancestry. He came into public notice by his work entitled *Degeneration*, published in 1895, in which he argued powerfully in defense of the proposition that the occidental nations are degenerating, morally, mentally, and physically. He held that in politics, society, and faith, the age is thoroughly decadent. The work evoked many replies, which kept it continually before the public. He had been writing for almost twenty years before, but only a few of his volumes had been translated into English. The best known of his works are *Paris Pictures*, *Conventional Lies*, *Paradoxes*, and *The Malady of the Century*. Since the publication of *Degeneration*, he has issued *The Comedy of Sentiment*, *The Right to Love*, *The Drones must Die*, with others of limited circulation.

Nordenskjold (*nor-dĕn-sheld*), **Nils Adolf Erik,** Baron, an arctic explorer, was born at Helsingfors, Finland, Nov. 18, 1832. He furthered the acquired taste for geology, chemistry, and mineralogy by studies at home and in Berlin. He was naturalized in Sweden in 1857, and in 1858 was made head of the mineralogical department of the royal museum at Stockholm. He mapped the south of the island of Spitzbergen, and after two trips

BARON NORDENSKJOLD.

to the mouth of the Yenesei, he completed the navigation of the northeast passage from the Atlantic to the Pacific, from June, 1878, to September, 1879, in the *Vega*. On the last of his two voyages to Greenland, in 1883, he traveled 140 miles from the east coast. He was made a baron in 1880. and has written *Voyage of the "Vega" round Asia and Europe*, *Scientific Results of the "Vega" Expedition*, and *Studies and Investigations*. See A. Leslie's *Arctic Voyages of A. E. Nordenskjöld*.

Nord'hoff, Charles, an American author, was born at Erwitte, Prussia, Aug. 31, 1830. He came to the states with his parents when a child of five years, and was educated at Cincinnati. He entered the United States navy in 1844, and during a service of three years made a voyage around the world. He afterward joined the commercial marine, remaining at sea most of the time until 1835, when he became a journalist, first at Philadelphia and later at Indianapolis. From 1861 to 1871 he was editorial writer for the *New York Evening Post*. The next two years he spent in travel through California and the Hawaiian islands. He then became Washington correspondent for the *New York Herald*. His principal works are, *A Man of War Life*, *The Merchant Vessel*, *Whaling and Fishing*, *Stories of an Island World*, *Cape Cod and All Along Shore*, *California*, *Politics for Young Americans*, *The Communistic Societies of the United States*, etc.

Nor'dica, Lillian, the stage name of Mrs. Zoltan F. Döme, an American prima donna, who was born at Farmington, Me., in 1859. Her earlier musical education was pursued at the New England conservatory, Boston, and her later studies at Milan, Italy. She made her debut as an opera singer at Brescia, Italy, in *La Traviata*. In 1887, she appeared in London with marked success, following up her triumphs in Paris, by others at St. Petersburg and various European capitals. Mme. Nordica has sung leading parts in forty operas and in all the standard oratorios. She was married first to a Mr. Gower; second to Herr Döme.

Nor'folk, a city and port of Virginia, stands on the right bank of the Elizabeth river, about eight miles from Hampton Roads. It is built irregularly on low ground, but has a large, deep harbor, defended by Fort Calhoun and Fortress Monroe. The city contains a city hall, mechanics' and masons' hall, custom house, military academy, and seminary, and ships cotton, oysters, and early fruits. The place was burned by the British in 1776, and was the scene of the battle between the *Monitor* and *Merrimac*. Population 46,624.

Nor'mal Schools are institutions for the especial instruction of teachers in the art and practice of their profession. The same schools in England are called training colleges. Students are admitted who have passed through the curriculum of any good grammar school, and who are between seventeen and twenty years of age; although in some schools candidates for entrance may be older. What was practically a normal school was opened in Edinburgh in 1830. Battersea training college is the oldest normal school in England, but it has about fifty successors now. Most normal schools in the states are modeled after those of Massachusetts, while those of Massachusetts take the Prussian schools as their models, with such adaptations as the state of education and society in our country necessitates. The oldest normal school in Massachusetts was established at Lexington in 1839. The latest statistics given by the Bureau of Education place the number of public normal schools at 167; and give the number of private normal schools as 178. In all these there are about 2,900 teachers and 68,000 pupils. In the public normals the proportion of female students is nearly three times that of the male students; in the private schools the sexes are nearly equal. About 3,000 negroes are pursuing normal courses. Sixty-one per cent. of those in normal schools are in teachers' training classes. Apart from studies bearing directly upon pedagogy the course of studies embraces those usually pursued in English high school courses.

Nor'man, Henry, an English journalist, was born at Leicester, England, Sept, 19, 1858. He studied, however, in this country, graduating from Harvard college in 1881, and passing the next two years at Leipsic, Germany. He then accepted a position on the *Pall Mall Gazette*, London, and later became associate editor of the *Daily Chronicle*. He was several times sent abroad upon important missions on account of his proficiency in modern languages. Having inherited a moderate fortune in 1888, he spent the following years in travels throughout the least known parts of Asia. He has published works upon *China*, *Corea*, *Japan*, *Siberia*, and the *Balkans*. His first book was an account of *The Harvard Greek Play*, in 1881. In 1895, he was sent to Constantinople to report upon the Armenian massacres; and from there he proceeded to Washington, D.C., to write for the London *Daily Chronicle* the status of the Monroe Doctrine. He married in London (1891) Miss Menie Muriel Dowie, who had previously published (1890) *A Girl in the Carpathian Mountains*, to secure material for which she had traveled in male attire through the wildest districts of the country described. He has published in recent years *The Real Japan*, *The Peoples and Politics of the Far East*, and *The Near East*.

Nor'mandy, an ancient province of France, bordering on the English channel, comprises at present an area of about 10,500 square miles, divided into the departments of the *Seine-inférieure*, *Eure*, *Orne*, *Calvados*, and *Manche*. The soil is fertile and the popula-

tion about 2,500,000. The present inhabitants are lineally descended from the ancient Normans, whose duke, William the Conqueror, in 1066, invaded England and established his dynasty upon the throne of that country. England and Normandy were thus under the same rulers until 1204, when Philip Augustus conquered Normandy and made it a part of France. It was reconquered by the English in 1415 at Agincourt, but again wrested from them by Charles VII. in 1449. The people are hardy, industrious, and exceedingly proud of their history. Their language and their art have left abiding evidences of their value upon the literature and architecture of France. The chief city of the region is Rouen (population 113,219).

Nor'mans. See NORTHMEN.

Norns. The fates of Scandinavian or Norse mythology were three maids named Urd, Verdandi, and Skuld, meaning past, present, and future. They were supposed to sit by the well of Urd, under the world tree in Asgord, and determine the fate of gods and men. There were also lesser norns, all working on the destinies of man.

Nor'ristown, a city, the capital of Montgomery county, Pa., stands on the left bank of the Schuylkill, 17 miles from Philadelphia. It contains a marble court house, a state insane asylum, cotton mills, woolen factories, rolling mills, foundries, flour mills, and glass and tack factories. Population 22,265.

North Adams, a manufacturing town of Massachusetts, is situated on the Hoosac river, near the west end of the Hoosac tunnel, 143 miles from Boston. It has large cotton and woolen mills, shoe and print factories, and foundries. Population 24,200.

North Cape, the extreme north point of Europe, is not on the continent, but is a promontory on the island of Magerŏe. The continental extremity is Cape Nordkyn, six miles south and 45 miles east of North Cape.

North Car'olina, one of the original states of the United States, lies on the Atlantic seaboard, directly below Virginia, and has an area of 52,250 square miles, that is, 7,000 square miles larger than Pennsylvania. The western part of the state is low and often marshy, rising gradually to the North Carolina mountains in the west, with Mount Mitchell (6,707 feet) for their highest point. The state's wealth is mineral; silver, lead, zinc, copper, plumbago, iron, corundum, and mica being found in almost all localities in large deposits. Agriculture is also an important interest, large crops of corn, cotton, wheat, oats, hay, tobacco, and sweet potatoes being produced. From the extensive forests of long-leaved pine, large quantities of tar, resin, and turpentine are shipped every year. The capital is Raleigh, and the other larger cities are Wilmington, Greensboro, Asheville, and Charlotte City. Sir Walter Raleigh first placed colonies in the state in 1585–86–87, but none became permanent. In 1653 a settlement was made on the Roanoke and Chowan rivers by colonists from Virginia, and in 1664 it was severed from Virginia by Governor Berkeley. It became a royal province in 1729, and so remained until May 20, 1775, when it declared its independence, and was the twelfth state to ratify the constitution. It was the last of the eleven states to secede from the Union in 1861. Population 1,893,810.

North Dako'ta, a northwestern state in the Union, was originally a part of the Louisiana purchase, bought from Napoleon by the United States in 1803. Since then it has belonged to the territories of Missouri, Michigan, Wisconsin, Iowa, Minnesota, and then of Dakota from 1868 to 1889, when North and South Dakota were admitted as states into the Union. It has a land surface, approximately, of 70,195 square miles, or nearly double the area of Indiana. North Dakota is called the Sioux state, or the land of the Dakotas, because the Dakota Indians who lived and ruled here were called by a name which the French traders rendered Sioux. The first settlement in the territory was made by French traders, in 1780, at Pembina. In 1875, there were less than one thousand white inhabitants in all North Dakota. The state has now 55 counties, 493 post-offices, 2,100 miles of railroad, 1,485 public schools with 36,000 children enrolled, 119 newspapers and 25 national banks in the area above stated. Fargo, Grand Forks, Bismarck, the capital, Jamestown, Wahpeton, Valley City, and Grafton are the chief cities. James River valley is noted as the wonderful artesian belt. Red River forms the eastern boundary of the state almost entirely, and thousands of logs from the Red lake and Otter Tail pineries are floated down to the Grand Forks sawmills. The land of North Dakota is fertile, the Red River region, a vast deposit of rich black loam, being noted for its bonanza wheat farms. The Dakotas rank high among the wheat-producing states, and the quality of the wheat is the best. Devil's Lake, called Spirit Water by the Indians, is 55 miles long and six miles wide. The Turtle mountains, which extend from Manitoba, cover 800 square miles of surface, the highest peaks being Butte St. Paul, and Bear Butte, 2,300 feet high. On the Little Missouri are the Bad Lands, 30 miles wide and 50 miles long, with huge pyramids, domes, towers, and spires of rocks and colored clays. The clay hills have been changed into terra cotta by the great beds of coal, which have been burning for ages, and are still burning in some places. The treeless region between the Missouri and James rivers is a stretch of ridges and fantastic shaped hills, crowned with masses of bowlders. The Missouri, which bends around through a great part of the state, is navigable

for steamboats for 1,200 miles. The main industry is farming; besides wheat, the chief product, corn, oats, barley, rye, and potatoes are raised. The entire western part of the state is a coal region, and the mines at Dickinson and Burlington, Minot and Sims, do a large business in coal every year. Population 319,146.

North, Frederick, eighth Lord North and second earl of Guilford, an English statesman, was born April 13, 1732, and educated at Oxford. He entered the house of commons at the age of twenty-two, and was made lord of the treasury in 1759. In 1767, he was appointed chancellor of the exchequer and leader of the house of commons, being there opposed to Fox and Burke. In 1770, he became prime minister, and his course, to a large extent, caused England to lose America. He resigned in 1782, and became blind five years before his death, which occurred Aug. 5, 1792.

North Sea or **German Ocean** is the southern arm of the Arctic ocean, lying between Iceland and Norway. It communicates with the Atlantic through the English channel and straits of Dover on the south, and by Pentland Firth and the Orkney and Shetland channels on the north, and with the Baltic through Skager-Rack and Cattegat. It is over 600 miles long and 400 miles wide, and has an area of 180,000 square miles. The sea is in most places quite shallow, averaging 61 fathoms, but on the Norwegian coast is 360 fathoms deep. It is the receptacle of the waters of the Thames, Ouse, Humber, Tyne, Tweed, Forth, Tay, Scheldt, Rhine, Weser, and Elbe. The water is probably the least salty of any of the large seas, and, except in the summer, is warmer than the surrounding atmosphere. The tides are irregular, having a large ebb and flow in some places, while it is hardly perceptible in others. The North sea has long been one of the commercial highways of the world, and affords a valuable fishing-ground.

Northamp'ton, the capital of Northamptonshire, England, is a municipal county and parliamentary borough, and lies on rising ground on the left bank of the river New. It is the center of the boot and shoe industry of England, and has extensive breweries. The city was burned by the Danes in 1010, rebuilt by Simon de St. Liz in 1075, besieged by the barons against King John in 1215, and was the scene of the treaty recognizing the independence of Scotland in 1318. Population about 75,000.

Northamp'ton, the county seat of Hampshire county, Mass., is situate near the left bank of the Connecticut river, 103 miles from Boston. It manufactures paper, silk, cotton, and woolen goods, sewing machines, baskets, cutlery, brushes, and jet ornaments. In the city are the state insane asylum, Clark institute for deaf-mutes, public library, and Smith college for women. Population 18,643.

North'men or **Norse'men** was a name applied in the middle ages to the seafarers who came from Denmark, Norway, and Sweden, and then to those of Norway only. Their passion was sailing and war, and to satisfy it they sailed in all directions to discover and plunder. In plain words, they were pirates, who, during the summer months, visited other lands and preyed upon them, or lay in wait in river mouths, or behind islands, for vessels to attack and pillage. Their age may be divided into two periods, the first lasting to the middle of the 9th century, devoted to murder and plunder, and from then to the 13th century, given to permanent conquest in Ireland, South Italy, England, and France. The first attack was made upon Wessex, in England, in 787, and reached France about the end of the century, and up to 850 they committed most terrible depredations. In 859 and 860, a large fleet entered the Mediterranean and ravaged Spain, Mauritania, and Majorca, spending the winter at the mouth of the Rhône, to begin the attack on Italy in the spring. Thus they subsisted on the entire seaboard of Europe until Charles the Simple concluded a peace, by which they were allowed to settle in France, and gave them the territory between the Channel, the Seine, and the Ept, on the condition that they fought for him and became Christians. The name of Normandy was given to this district, and the Northmen living in it were called Normans. They ruled here from the 10th to the 13th century, when it was taken from them by the king of France, the most illustrious of their dukes being William who became king of England in 1066, with the title of William the Conqueror. The Normans adopted the language and manners of the French, and changed their heathen rites for the Christian religion. The Norsemen, early in the 9th century, had opened the route to the White sea by rounding North cape, and before 1222 had many times sailed up the northern Dwina.

North'west Territories, The, a part of the Dominion of Canada, comprise the provinces of Alberta, Assiniboia, Athabasca, and Saskatchewan, besides an unorganized expanse estimated at 906,000 square miles. The territories named contain about 550,000 square miles with a population of about 145,000, exclusive of 20,000 Indians. All of this region with Manitoba was, up to 1870, under the direct control of the Hudson Bay company, by whom it was treated as a vast hunting preserve. The Northwest territories are presided over by a lieutenant-governor and a legislative assembly, and have an executive council composed of a lieutenant-governor and five members who are elected by the people. The territories are also represented in the dominion parliament by four members.

The seat of their own united government is, since 1883, at Regina (population 2,000), in the Province of Assiniboia. The Canadian Pacific railroad traverses both Assiniboia and Alberta, and branch lines are being rapidly constructed to open up the vast district lying upon either side of the main line. About one half the population is Protestant; about one seventh Catholic, and pagan Indians constitute the remainder. Coal, both anthracite and bituminous, is found in large quantities. Most of this region is susceptible of cultivation and produces all small grains. There is less waste land north of the international boundary than south of it. The country is very rich in natural resources, and despite its severe winters it is destined to be the seat of a large and prosperous population.

North'west'ern University, a Methodist Episcopal institution, is located at Evanston, Ill., twelve miles north of the center of Chicago. It was first opened in 1855. The university comprises the following departments, each having a distinct faculty of instruction: the college of liberal arts, the medical school, the law school, the school of pharmacy, the dental school, the woman's medical school, the school of music. Garrett biblical institute, though under a separate management, is closely affiliated, and serves as the theological school of the university. The university has a permanent productive endowment of $2,950,000, with an annual income, exclusive of benefactions, of $390,000. The value of its buildings and grounds is $2,096,000. The college library contains 45,764 volumes and 30,000 pamphlets. The faculties number 229, and the number of students in degree-conferring departments is 2,246.

Nor'ton, Charles Eliot, an American author and educator, was born at Cambridge, Mass., Nov. 16, 1827. Young Eliot graduated at Harvard college in 1846, and traveled in Europe and the far east for the following two or three years. He spent altogether nine years abroad between 1849 and 1873. In 1864–68, he was joint editor with Lowell of the *North American Review*. In 1874, he was appointed professor of the history of art at Harvard, and in 1879 he became president of the Archæological institute of America, holding that office for eleven years. He received the honorary degree of Lit.D. from Cambridge, England, and LL.D. from Harvard. He has published and edited about 20 volumes. His writings have largely dealt with art and sociology, as in his *Recent Social Theories* and *Historical Studies of Church Building in the Middle Ages*. He has written lives or edited works of *Dante*, *Michael Angelo*, *Carlyle*, *Emerson*, *Lowell*, etc.

Nor'walk, a town of Connecticut, in Fairfield county, at the mouth of the Norwalk river on Long Island sound, 41 miles from New York. It has the largest straw hat factory in the United States and large manufactories of felt hats and goods, woolens, shirts, shoes, locks, door knobs, besides foundries and iron works. It has a good harbor and large oyster fisheries. Population of Norwalk city, 6,125; of South Norwalk city, 6,591 — total, including Norwalk town, 19,932.

Nor'way, the western and northernmost part of the Scandinavian peninsula, united to Sweden only through having a common ruler; it is divided from Sweden by the Keel mountains, which run parallel to the coast from the north to 63° and then separate, the main division continuing to mark the boundary by a plateau from 2,000 to 4,000 feet wide. The higher peaks are Galdhopiggen, Glittertind, 8,379 feet; Snæhaetten, 7,566, and Lodalskaupen, 6,790. Bear, lynx, and deer abound in these mountains, and the only inhabitants are the men and women who tend the large herds of cattle and sheep. On account of the Gulf stream the winter on the west coast is much warmer than in the interior, whereas the summer is much cooler. The largest cities are Khristiania, the capital (population 225,686); Bergen, Trondhjem, Stavanger, Drammen, Khristiansand, and Fredrikstad. The hardiest grains and vegetables flourish, but the occupation of the people is mainly connected with the great fisheries. The mineral wealth of Norway has been practically exhausted since 1870, only a few mines being now worked. Norway is divided into twenty districts (Amter), has an area of 124,445 square miles, and an estimated population in 1900 of 2,231,395. It is nominally a limited monarchy, but actually, to all intents and purposes, is almost a free republic. The head of the government is a king, at present (1901) Oscar II. of Sweden and Norway, but his acts are limited by an appointed executive council of eight and three ministers of state. One of the first peoples to settle Europe, their history does not, however, become free from myth until the 9th century, when the Lapps and Finns were found in the country by the Gothic descendants, who then crossed the Baltic and settled there. For a long time it was a part of the kingdom of Denmark. Her history is intimately associated with that of the Norsemen, who were a part of her people, but from 1130 to 1240 the country suffered both in war and in commerce, and commenced a rapid retrograde movement which did not end until it was attached to Sweden in 1814. All titles of nobility were abolished in 1821, and in the struggle from 1872 to 1884 the right of veto was taken from the king. See Carlyle's *Early Kings of Norway*, and Boyesen's *History of Norway*.

Nor'wich, the capital of Norfolk, England, a municipal county and parliamentary borough, lies on the Wensum, 114 miles from London, and covers an area of about 10,000 acres. It contains Pull's ferry and Bishop's

bridge (1295), St. Giles' hospital (1249), Ethelbert gateway (1300), Guildhall (1413), the music house, Bridewell and Dolphin inn, — all old buildings. It also has a cathedral, founded in 1096, which has a spire 315 feet high. The principal manufactures are crapes, mustard, starch, ironware, and boots and shoes. The city in olden times was often plundered by the Danes, then burned by Sweyn and held by Canute. It has been the seat of sixty-five bishops. Population about 110,000.

Nor'wich, county seat of New London county, Conn., stands at the head of the Thames river, the chief portion of the town lying on an eminence between the Yantic and Shetucket rivers, which here unite. It manufactures paper, cotton, and woolen goods, cords, pistols, wood type, files, locks, iron pipes, and has large rolling-mills and iron works. The land on which it stands was given to an Englishman by Uncas, the chief of the Mohicans, in 1656. Population 17,251.

Nose, the external organ containing the nostrils and connected with the sense of smell. Many lower animals possess the power of smell but have no nose. The nose proper begins in the vertebrate animals. The nostrils serve as paths for air into the respiratory passages. They lead also into the chamber of the nose, which is divided by a flat bony partition into right and left sides. The walls of each cavity are convoluted (*turbinated bones*), and covered with a soft membrane from which the nerves of smell pass to the brain. The sense-cells, which are especially modified for smelling, are located in the membrane, and the nerve fibers forming the olfactory nerve grow from them. The olfactory nerve usually enters into an olfactory lobe before making connection with the brain.

Not'ting'ham, the capital of Nottinghamshire, England, a municipal county and parliamentary borough, lies on the Trent, 126 miles from London. It was formerly surrounded by high walls, which have now disappeared, and the 20 square miles of the city have of late been much improved by the widening of the streets and the erection of new buildings. It contains a city hall, St. Mary's church, guildhall, university college, a library and museum, besides an old hospital, and Roman Catholic cathedral. The most important manufactures are lace and hosiery, but baskets, bicycles, cigars, and needles are also manufactured. The principal events of its history are the occupation by the Danes until 868; destruction by fire in 1140 and 1153; its first charter in 1155, the convention of three parliaments and the raising of the standard of Charles I. in the parliamentary war in 1642. Population about 240,000.

No'va Sco'tia. The province of Nova Scotia (including Cape Breton island, at its northeast extremity) has an area of 20,600 square miles. It is connected with New Brunswick by an isthmus, about sixteen miles wide, being otherwise surrounded by the waters of the Atlantic, bay of Fundy, and Northumberland strait. Its capital, and the seat of the provincial government, is Halifax, with one of the finest harbors in the world. Owing to its insular position, the Nova Scotian climate is more limited than that of inland portions of the Dominion, making the colony very suitable for high cultivation. The fertility of the soil, especially in the Annapolis valley and round the Basin of Minas, is unsurpassed, arising in part from the rich marine deposits left on the coast lands by the tides of the bay of Fundy. Large areas of the salt marshes have of recent years been reclaimed by a system of mud dykes, and yield largely of a valuable salt hay, as well as rich crops from the productive meadow-land. Fruit is also profitably cultivated, especially the famous Nova Scotia apples. There are still also excellent hunting, shooting and fishing, in various sections of the province, while it has considerable mineral wealth, especially of coal.

Historically, Nova Scotia has an attractive interest for the student who knows Acadian annals, and finds zest in the long conflict between France and England for mastery in the New World. The flames of enmity between these two European nations continued intermittently to blaze and smolder for a century and a half, until the fall of Quebec and the final retirement of the French from the continent. The first direct collision between the two powers in Acadia was Argall's expedition from Virginia, which captured the fort and destroyed the French settlement at Port Royal. This occurred in 1618. Then came the expedition against the same beautiful land-locked basin and frowning fort, sent out by Cromwell, followed by Phip's expedition from New England, its reinvestment and recapture in the time of Queen Anne, when its name was changed to Annapolis; after which Louisburg, with its extensive fortifications, became the scene of conflict and the grim test of British and colonial prowess. On the fortress of Louisburg, the "Dunkirk of America," the French expended thirty thousand livres, only to see it fall with frightful carnage, first, before the assault of Colonel Peperall's colonial levies, aided by the British fleet; then, and finally, before Admiral Boscawen's armada, assisted by the invincible brigades of General Wolfe's command, who were soon to terminate, on the heights of Quebec, French dominion in North America. As an incident of this struggle of races in Acadia, we have that most pitiful historical pendant, the expulsion of the French Neutrals with their belongings from the beautiful Basin of Minas and the land celebrated in Longfellow's *Evangeline*. Stern was the necessity for this banishment of the Acadians from the

reclaimed land of Grand Pré; but tragic as is the story, it is well to remember that the narrative embodied in the poet's romance is not altogether to be taken for history. For the story of other dramatic incidents connected with the period of French occupation of Acadia — such as the long quarrels of the rival French governors, Charnissay and De la Tour, and the heroism of the latter's noble wife — the reader is referred to the Acadian annalist, and especially to the works of the historian, Francis Parkman.

Representative government was established in Nova Scotia in 1758, with Halifax as a capital of the colony. At this era, Nova Scotia also included Cape Breton and what is now known as New Brunswick. In the year 1784, however, both of these territories were organized as separate provinces, Fredericton becoming, four years later, the capital of New Brunswick, with Sidney as the chief town of Cape Breton. In 1820, the island of Cape Breton was re-annexed to Nova Scotia. Prince Edward Island (or what was then called The Island of St. John), on its cession in 1763 by France, became also a part of the province of Nova Scotia. In 1770, however, it was made and has since remained a separate province, with representation from 1873, when it entered confederation, in the Dominion parliament. Nova Scotia has to-day a population estimated at 459,116. Besides its representation in the senate and in the house of commons, in the Dominion parliament at Ottawa, it has a local parliament with one chamber, with an executive and a lieutenant-governor. The local assembly meets at Halifax. The educational institutions of the province include, in addition to the elementary schools, Dalhousie college and university (Halifax); university of King's college (Windsor); university of Acadia college (Wolfville); university of St. Francis-Xavier college (Antigonish); St. Ann college (Church Point); together with a Presbyterian college, and a ladies' college, at Halifax; a Church school for girls, at Windsor; Acadia seminary at Wolfville; and a provincial school of agriculture at Truro. The chief towns, besides Halifax, are Lunenburg, Liverpool, and Shelburne, to the northwest of the capital; Yarmouth, at the entrance to the bay of Fundy; Annapolis, at the eastern side of that bay; Pictou, on the northwest coast of the peninsula, and Windsor, in the interior. The only town of note on Cape Breton is Sidney, on the east coast, with important collieries in the vicinity. Louisburg is now a dismantled ruin, the great fortifications of the place having been demolished in 1758. See Hannay's *Nova Scotia*, and *Appleton's Canadian Guide-Book*, Part I.,— Eastern Canada,— by Charles G. D. Roberts.

No'va Zem'bla, an island in the Arctic, lying between the Kara and Barents seas, is about 600 miles long and 60 wide, almost cut into two narrow strips by the sea passage Matochkin Shar. Nothing is known of the interior, and it is only visited by Russians and Norwegians to capture sea fowls, seals, whales, walrus, and dolphins. The country was known to the Novgorod hunters in the 11th century, and rediscovered by Sir Hugh Willoughby in 1553, and has since that time afforded a place of much search and interest. Much has been learned of the country, which may be said to be uninhabited, since 1868.

Novem'ber, from the Latin, meaning "nine," was the ninth month of the Roman calendar year, when there were thirty days to the month of November and ten months to the year. Then it was given only twenty-nine days, but Cæsar gave it thirty-one, only to have it restored to thirty by Augustus. Its festivals are All Saints (1), St. Hubert (3), St. Martin (11), St. Catharine (25), and St. Andrew (30).

Nov'gorod ("new town"), a famous Russian city, capital of a government, is situated near lake Ilmen on the Volkhoff river. In 864, Rurik, a Norseman, was invited here to rule, and with him begins the history of the country. In the 12th century the city, which then had 400,000 inhabitants, was the market of northeastern Europe, and its almost republican government ruled from the White sea to the river Petchora. In 1471, on account of the jealousy of the Moscow princes, the czar Ivan III. destroyed Novgorod, deprived it of its liberties, and exiled its best citizens. Afterward the port of Archangel was opened and the city began to decline. The oldest building is the Church of St. Sophia, founded in the 11th century, besides thirty other churches and the wall surrounding the Kremlin. Population 26,095.

Nu'bia, the modern name of a large African region, formerly part of Ethiopia, and extending on both sides of the Nile from Egypt to Abyssinia and from the Red Sea on the east to the desert on the west. Of late, Nubia has been called the Egyptian Sudan. It was under the rule of the Pharaohs, but under the 20th dynasty was recovered by native rulers, who adopted Egyptian civilization and later became Christianized. The country is now occupied by mixed races, probably descendants from the pure negro stock mixed with the Hamatic and Semitic Arabs who invaded the land in the 7th century, and conquered it in the 14th. Until 1820, it was ruled by native Moslem chiefs, but in that year it was made a part of Egypt by Ismail Pasha, and so remained until 1881. The greater part of the country is arid desert, with small oases here and there on the route of caravans. The most fertile region is near Dongola. Its population, which consists chiefly of Egyptians, sedentary and nomad, number 240,382.

Nucellus (*nū-sĕl'lŭs*), (in plants), the main body of an ovule, usually more or less

invested by an integument or integuments. It is the nucellus which is really the megasporangium, and which contains the megaspore or embryo-sac. See OVULE.

Nucleus (*nū'klē-ŭs*), (in plants), a special protoplasmic body always found in cells. So far as known, every cell must contain nucleus and cytoplasm. In the process of ordinary cell division the initial steps are taken by the nucleus. Ordinarily, the nucleus is a spherical body and is usually centrally placed. It is difficult to see under ordinary circumstances without the use of special stains which color it. See CELL.

Nu'ma Pompil'ius, the second Roman king, (who ruled 715–672 B. C.), successor to Romulus, was a native of Cures, in the Sabine country, and esteemed for his piety and wisdom. He was elected king by the Roman people and by the aid of supposed interviews with the nymph Egeria in the groves near the city began to draw up forms of religious institutions for the people, and was thus, according to story, the author of the Roman ceremonial. He reigned during thirty-nine years of peace and happiness.

Numid'ia, the name given by the Romans to that part of Africa which is now Algiers, and reaching south to the Atlas mountains. The inhabitants were of the race from which the Berbers are descended; were warlike, faithless, dishonest, yet excellent horsemen. In the war between the Carthaginians, Massinissa, the chief of the powerful eastern tribe, joined the Romans and later ruled the entire country. Of his successors Jugurtha and Juba are best known. After Cæsar conquered Juba I., Numidia became a Roman province, but Augustus gave the western part to Juba II. Among the more important places were Hippo, Raguis, Zama, and Cirta, afterward called Constantina, and now Constantine.

Nur-ed-Din' Mahmud, emir and sultan of Syria, was born at Damascus in 1116. He is noted for his defeat of the first and second crusades of the Christians, the conquering of Tripolis, Antioch, and Damascus, and the taking of all the Christian strongholds in Syria in 1151. In 1168, he was made sultan of Syria and Egypt, and while preparing to invade Egypt, died at Damascus in May, 1173. He was the bitterest enemy of Christianity, but was a patron of science, art, and literature, and a good administrator of justice.

Nu'remberg, a city in Middle Franconia, a province of Bavaria, stands on the river Pegnitz, 95 miles from Munich. It is one of the most interesting cities of Germany, with its old walls, gates, bridges, and fountains. The castle, built by Conrad II. and Frederick Barbarossa, is famed for its paintings and wood carvings. The most notable buildings are St. Lawrence church (1274), St. Sebald's church (1225), the Italian Renaissance town hall (1622), the gymnasium (1526), the new law courts, the Germanic museum, and the library of 70,000 volumes. The city has no foreign commerce outside of that in toys, known as Nuremberg wares, but has a large home trade in metal and wood specialties, bone carvings, type, lead pencils, and chemicals. Nuremberg was first heard of in 1050, and became a free city in 1219. The Hohenzollerns sold their rights to it in 1417, and it immediately began to rise as the German home of arts and inventions and became a center of commerce. The discovery of the Cape passage to India, and the Thirty Years' war, proved the city's ruin, and although it retained its independence until 1803, it entered the Rhenish confederation, and in 1806 became one of the cities of Bavaria. Population 261,022.

Nuta'tion, regular bending of plant parts, such as bud scales, flower leaves, stems, etc., due to unequal growth on the sides. The stimulus inciting it may be light, heat, or gravity. (See IRRITABILITY.) Thus the flowers of the tulip and crocus are sensitive to temperature changes of a few degrees, opening with rising and closing with falling temperature, because the growth of the outer face is hastened and that of the inner face retarded, and vice versa. When a cylindrical stem has its growth hastened on every side in regular succession, the tip describes a more or less regular circle, as in twining plants like the hop and morning glory. Some nutations are apparently spontaneous.

Nut'hatch, a small creeping bird seen running up and down the trunks of trees. The feet have sharp claws which adapt them for holding to the bark, the tail is short and square, and is not used to assist the bird in climbing. They feed upon insect's eggs and larvæ, which they find on the trees, and also on nuts. With their rather slender bills, they excavate a hole for a nest in some decayed limb. The white-breasted nuthatch, bluish-gray above, whitish below, is common in the United States, and remains throughout the year as far north as New England. It is very nimble, and may be seen running rapidly in any direction on the bark of trees. It is also called sap-sucker. The red-breasted nuthatch is more northernly in its range, nesting from Maine northward and in the mountains further south.

Nut'meg. See SPICES.

Nutri'tion (in plants), the processes by which food is obtained and utilized. Plants obtain their food (which see) in two ways, by absorption and by manufacture. With a few exceptions, plants which obtain their food ready-made are unable to engulf it and must take it into the body in solution. (See ABSORPTION.) If insoluble in water, they must first digest it. (See DIGESTION.) All prepared food is derived directly or indirectly from other

organisms. A few plants capture small insects for the sake of the food derived from their bodies. Parasites, that is, creatures growing on or in a living being (called, therefore, the host), derive their food directly from it; saprophytes in a similar way obtain their food from a dead organism. There is every possible gradation between parasites and saprophytes; and between saprophytes and green plants, which are able to make all of their food out of inorganic material. Yet many green plants absorb organic matter, *i.e.*, matter once a part of a living being; this is the reason for applying fertilizers and manures to gardens and fields. Many, perhaps all, colorless plants can make the most complex foods (proteids), provided simpler foods and necessary salts are supplied. Only green plants, however, and of these only the green parts, can make carbohydrate foods, like sugars, starch, and the like, out of carbon dioxide, and water. (See PHOTOSYNTHESIS.) When these foods have been formed in sufficient amount, the green plants can also produce proteids. Most plants make more food than they require. Reserve food is stored, usually in solid form, in special tissues. These storage regions have been greatly improved by cultivation, the common vegetables (seeds, tubers, bulbs, roots, leaves, and even flower buds) being the product of proper breeding and of growing the plants under unusually favorable conditions for nutrition. In its broadest sense, nutrition includes the use of foods in assimilation, respiration, and growth. These topics are separately treated. In the course of the chemical processes of nutrition (see METABOLISM) a great variety of waste products arise, such as gums, resins, volatile oils, tannins, alkaloids, etc. These the plant secretes and removes them thus from its general metabolism. See SECRETION.

C. R. BARNES.

Nyas'sa or **Nyanja,** the most southern of the great East African lakes, is 260 miles from Tanganyika and 400 miles from the east coast. It is 1,570 feet above sea level, very deep, rapidly descending from its high and rocky shores, and measures about 350 miles long by 40 miles broad from east to west. It was known by the Portuguese as Maravi in the 17th century, but was first navigated by Livingstone, and its situation exactly determined in 1859.

Nyassal and (*n.i-ăs'să-lănd*), the name given to a British Central Africa protectorate, the country lying immediately south, west, and northwest of Lake Nyassa, in East Africa. It has no outside boundaries, but is the region in which the African Lakes company of Glasgow operates in connection with the missionaries of the Church of Scotland, with principal stations at Blantyre and Bandawe. The company and mission stations were founded on the recommendation of Dr. Livingstone to check the Arab slave trade. It is now under the administration of the British foreign office, by a resident commissioner. Its products are rice, coffee, rubber, and ivory. The capital is Blantyre. Some trouble has been caused of late by the claim of sovereignty made by Portugal; but the sphere of the Nyassa company, with a royal charter from the Portuguese crown, is the region between the Rovuma, Lake Nyassa, and the Lurio.

Nye, Edgar Wilson, an American writer and humorist who wrote largely under the pseudonym of "Bill Nye," was born at Shirley, Me., Aug. 25, 1850. He was but two years old when his parents moved to St. Croix county, Wis., where he received a common school education. He studied law there and later went to Wyoming where he was admitted to the bar and elected to the legislature. He also acted as postmaster and newspaper correspondent. On account of ill-health he returned to the east and settled in New York, where he was offered a large salary, as it seemed to him, on account of the notoriety his humorous contributions to the press had achieved. His first book, published in Chicago in 1881, was entitled *Bill Nye and the Boomerang*. In connection with James Whitcomb Riley, "the Hoosier poet," he made a tour of the country giving entertainments consisting of lectures and readings, which tour covered some years following. In 1891, he wrote a play called *The Cadi*, which appeared at the Union Square Theatre, New York. Although he issued a number of books, they were of an ephemeral character, and the humor which characterized them was largely dependent upon incidents now forgotten. He died at his home near Asheville, N. C., Feb. 22, 1896.

Nymphs, of Greek mythology, were the female divinities of the lower rank, inhabiting the seas, streams, groves, meadows, and pastures, caves, fountains, hills, and trees. Of their different classes were Oceanides, nymphs of the great sea; Nereids, of the inner sea; Potameides, of the rivers; Naiads, of fountains, brooks, lakes, and wells, and Dryads, of the trees and forests, who were supposed to die with the trees in which they lived. They were the goddesses of moisture, had power of prophecy, and guarded the nourishment and growth of infants. Many of the most beautiful Grecian sculptures are those of nymphs.

O

Oak, species of *Quercus*, a genus containing about 200 species, all natives of the northern hemisphere. About 50 species belong to North America, and among them occur some of the finest and best known of our forest trees. They are easily recognized by their characteristic leaves, and especially by their peculiar fruit, the well-known acorns. Among our most conspicuous species are the white oak (*Q. alba*), red oak (*Q. rubra*), scarlet oak (*Q. coccinea*), burr oak (*Q. macrocarpa*), chestnut oak (*Q. acuminata*), and live oak (*Q. Virginiana*). The last is a beautiful southern form with evergreen leaves.

OAK BRANCH IN FRUIT.

Oak Apples, called also nutgalls and gallnuts, are round balls about as large as an apple, found on the leaves and stems of oak trees, and are produced by the action of insects. The insect pierces the plant, and places an egg with a small quantity of poisonous fluid in the opening. The gall, or apple, grows rapidly and is fully formed before the egg hatches. The insect remains in the apple during its second stage, and finally as a gallfly eats its way into the world. The nuts are used in making ink and tannin.

Oak'land, a city of Alameda county, Cal., is situate on the east side of San Francisco bay, four and one-half miles from San Francisco. It is a beautiful city, well shaded and watered, with many fine residences — many of them the homes of the business men of San Francisco. The Congregational Theological seminary and a Catholic college are established here, and at Berkeley, four miles north, is the state university. The city manufactures cotton and woolen goods, jute, iron, nails, shoes, and pottery, and has large canning factories. Population 66,960.

Oasis (*ō'ā-sis*), a fertile spot in the desert, due to the presence of wells or underground springs. The French have made oases in the Algerian deserts by sinking artesian wells. Some of these spots in the African deserts are large enough to be inhabited, and grow crops of rice and millet, and are shaded with palms.

Oats, species of the genus *Avena*, belonging to the grass family. The common cultivated oat is *A. sativa*, which is native to the eastern hemisphere. The genus contains about 50 species, which are widespread in the north temperate regions. In the United States three species occur, the purple oat (*A. striata*), Smith's oat (*A. Smithii*), and the common wild oat (*A. fatua*). The cultivation of *A. sativa* and its varieties as a commercial industry is too well known to need description.

Oaxaca (*wä-hä'kä*), a state of Mexico, near the isthmus, is bounded on the north by Puebla and Vera Cruz, east by Vera Cruz and Chiapas, south by the Pacific ocean, and west by Guerrero. It contains an area of 35,382 square miles and the population is estimated at 872,902 persons, of whom the much larger part are civilized Indians. The greater portion of the area is mountainous, the Sierra Madre del Sur rising to a height of 1,200 feet, and running across the whole width of the state from east to west. The capital, of the same name, 210 miles southeast of Mexico city, has about 32,500 population. The resources are among the best in Mexico, its elevation giving it a considerable rainfall and a less oppressive climate than that found in several of the states of that country. Its soil is good, and wheat, coffee, sugar, cotton, cocoa, plantains, and fruits of all kinds are exported.

Obadi'ah, one of the twelve "minor prophets," of whom almost nothing is known. The book that bears the name was written probably about 587 B. C., and is in two divisions, one prophesying destruction to Edom, and the other foretelling the restoration of Israel. See *Minor Prophets*, by Farrar.

Ob'elisk, a memorial monument of stone with a pointed top. It has usually four faces, and is broadest at the base. The height varies from a few inches to 100 feet. These monuments were used by the Egyptians at the entrances of their temples, probably to record the honors and triumphs of their kings. They are covered with inscriptions, in Egyptian hieroglyphics, or picture writing. They are very ancient, going back to the 4th dynasty in Egypt, though the larger part date from the 18th and 19th dynasties. Two large ones, which stood at Heliopolis, were carried by Rameses II., one of the Egyptian kings, to Alexandria, and have been called Cleopatra's Needles. One of these was erected on the Thames embankment in London in 1878, and the other, presented by the khedive of Egypt to the United States, is in Central Park, New York. There are other of

these Egyptian obelisks at Rome, Florence, Berlin, and Paris. The Washington monument, finished in 1885 in the city of Washington, is an obelisk, and the largest in the world. It is 55 feet square at the base, and 555 feet in height. See *Egyptian Obelisks*, by Gorringe.

Ober-Ammergau (*o'ber-am'er-gow*), a village in Bavaria, 45 miles southwest of Munich. It is celebrated as the place where the famous miracle play, representing the Passion of our Saviour, is played once in ten years. It is the only survival of the old miracle plays, being excepted from the order abolishing them in Europe in 1779. In 1633, in gratitude for an escape from the plague which devastated the surrounding country, the people of the village vowed to perform this play once in ten years. The actors, in number 350, and the chorus of 80 members, are all taken from the villagers. It is played for twelve Sundays, in a large theatre holding 5,000 spectators, many of whom are visitors from all parts of Europe. See *Homes of Ober-Ammergau*, by Greatorex.

Oberlin College, located at Oberlin, O., thirty-four miles west of Cleveland, was established in 1833, and was chartered as "Oberlin Collegiate institute." In 1850, the name was changed to "Oberlin college." It is a coeducational institution and besides the college, theological seminary, and academy, provides courses for graduate students. The number of instructors, in all departments, including the conservatory of music, is 83, and the students in attendance in the college department 417.

Oberlin, a town in Lorain county, O., near Lake Erie, 34 miles west of Cleveland. It is a college town, with some factories and business blocks. It is the seat of Oberlin college, founded in 1833, and for some time was very unpopular because of its receiving colored students. It is now one of the large colleges of the country, with over 80 instructors and about 1,320 students of both sexes, with some very fine buildings. Population 4,082.

Oberlin', Johann Friedrich, a German minister noted for his benevolence, was born at Strasburg, Germany, Aug. 31, 1740. He became the Protestant pastor of Waldbach, a village in a wild mountainous district of Alsace. The country had suffered terribly in the Thirty Years' war, and the people were very poor and ignorant. Oberlin gave his life to elevating them, introducing better modes of farming, and some manufactures, making roads and bridges, founding libraries and schools, among them the first infant schools. The population increased from 500 to 3,000 during his life. Though laboring in a small sphere, his reputation for philanthropy has extended over the world. He died June 1, 1826. See *Life*, by Butler.

Obi (*o-bē*) or **Ob** is the great river of western Siberia. It rises in two branches in the Altai mountains in the Chinese dominions, and flows north, 2,120 miles, into the gulf of Obi in the Arctic ocean. It is very little used for navigation, but with the growth of the country will probably become one of the great water routes for commerce. Its chief tributary is the Irtish.

Observ'atory, an institution equipped for the study of astronomical or meteorological phenomena. In distinction from a laboratory, which is a place where phenomena can be brought to pass and where experiments can be tried, an observatory is a place intended for the observation of phenomena over which we have no control, such as an eclipse of the moon or a sudden variation in the earth's magnetism. Those institutions which are exclusively devoted to observational work are the purely astronomical observatories. Scarcely any other kind existed previous to the invention of the spectroscope by Kirchhoff and Bunsen. Recently, however, a number of astrophysical observatories have been established—notably at Potsdam in Germany, at Meudon in France, at Tulse Hill in London, at Cambridge, Washington, Allegheny, Columbus, Lake Geneva, and Mount Hamilton in America. In these institutions many experiments have to be tried as well as many observations made; for the spectra of various stars, planets, nebulæ, comets, etc., have to be interpreted as well as described. And their interpretation can be given only after experiment has shown how to duplicate them. Hence an astrophysical observatory is generally also a laboratory, provided with electrical, photographic, and spectroscopic apparatus. The same is more or less true of a magnetic observatory.

The typical astronomical observatory is equipped with a clock and an instrument for correcting this clock from the passage of stars over the meridian of the place. It is provided also with a telescope, housed in a dome which can easily be opened to the sky on one side and easily rotated. The more important observatories of the world are as follows: The Yerkes observatory at Lake Geneva, with a refracting telescope whose object glass is 40 inches in diameter; the Lick observatory at Mount Hamilton, Cal., with an objective of 36 inches diameter; the Harvard college observatory at Cambridge, Mass., with a branch in Arequipa, South America; this institution employs between 30 and 40 workers and is making a superb spectroscopic survey of the heavens; the Naval observatory at Washington and the McCormick at the University of Virginia each have 26 inch glasses, while the Halstead observatory at Princeton university follows with one of 23½ inches. The Greenwich observatory in England is a national institution, which has a brilliant history and is doing a great variety of work. The corresponding institution for France is the Paris

observatory, and like Greenwich in England and Pulkowa in Russia, has a history of which it may well be proud, but which is too long for discussion in this place.

Obsid'ian, a natural glass, a variety of lava. It is hard, brittle, with a glassy luster, partially transparent, and sharp edges that cut like glass. It is black, dark gray, green, red, brown, striped or spotted, a specimen usually having but one of these various colors. It is used for jewelry and ornamental articles, and in early times was employed for arrow-heads, knives, and mirrors. It is found in the Yellowstone park, and at other localities in the United States; in Iceland, the Lipari islands, Vesuvius, Sardinia, Hungary, Spain, Mexico, and South America.

Ocelot (*o'ce-lot*), a leopard-like cat inhabiting the wooded parts of America from Arkansas to Patagonia. It varies in length from two to three feet, and a full-grown animal reaches a weight of twenty-five pounds. Its fur is tawny or reddish-gray, marked with black spots and elongated blotches. The black color is sometimes in the form of a ring inclosing a spot somewhat darker than the general color of the fur. The ocelot is an agile climber; it feeds on birds and other small animals, and is very bloodthirsty.

OCELOT.

O'Con'nell, Daniel, the Irish "liberator," was born in County Kerry, Ireland, Aug. 6, 1775. He was brought up by an uncle, and studied in France at the College of Douai, from which he was driven to England by the breaking out of the revolution. He was admitted to the Irish bar in 1794 and became famous as counsel, the "counselor" being one of the titles by which he was known among his followers. His large practice, worth, he said, $35,000 a year, was sacrificed for his country, when he took a leading part in Irish politics. He was head of the Catholic party and contended for the admission of Catholics to parliament, which he secured in 1829. Noted for his fierce attacks on his opponents, he received several challenges to duels, but fought only one, in which he unfortunately killed his antagonist. He settled a pension on the widow, and vowed never to fight again. In 1823, the Catholic association formed by him became very powerful, with a large income. This was followed by a new political society, called "The Friends of Ireland of All Religious Persuasions," which, when suppressed, was followed by a succession of others under new names. He entered parliament in 1829, supporting the Whig party during the reform struggle, advocating free trade in corn, negro emancipation, the repeal of the laws against the Jews, and universal suffrage. He believed that Ireland would never have her rights until the act of union with Great Britain should be repealed; but in all his efforts to accomplish it, and to arouse the Irish nation, he was careful not to use force, or allow anything criminal. "He who commits a crime adds strength to the enemy," and "No political change whatever is worth the shedding of a single drop of human blood," were sayings of his. One of the greatest of orators, his remarkable speeches in parliament, one of which lasted for seven hours, were equaled only by his popular addresses throughout Ireland.

In 1840, he founded his famous Repeal association, the members of which paid from $50 to 25 cents annual fees, and which in 1843 had an income of over $200,000. The country then was thoroughly aroused, O'Connell traveling in one year over 5,000 miles, and addressing monster meetings that were held everywhere. The largest one, held on the Hill of Tara, Aug. 15, 1843, was attended by 750,000 people. A great meeting appointed for Sunday, Oct. 5, 1843, was prevented by the English government, which was now alarmed, and had sent 35,000 men into Ireland. In 1844, O'Connell, with his son and five others, was tried for sedition and sentenced to imprisonment for one year, and a fine of $10,000, and though the house of lords soon set aside the verdict, the fourteen weeks he was in prison brought on the ailment of which he died. The new party in Ireland, "Young Ireland," now separated from O'Connell because of his unwillingness to use force in obtaining the independence of his country, withdrawing from the association. The potato famine followed, and sick with the sight of the suffering of his country, sad with the consciousness of failure, and worn out with a struggle with disease, he left Ireland for Rome, longing to die there, but only reached Genoa, where he died May 15, 1847. His heart, at his own request, was carried to Rome, and his body buried at Dublin, at the base of a tower 165 feet high. "Grattan sat by the cradle of his country and followed her hearse; it was left for me to sound the resurrection trumpet, and to show that she was not dead but sleeping" is his own verdict on his work for Ireland. See *Leaders of Public*

Opinion in Ireland, by Lecky; *O'Connell* in the "Statesmen" series; *Life*, by his son John O'Connell.

O'Con'nor, Thomas Power, an Irish statesman, was born at Athlone, County Roscommon, Ireland, Oct. 5, 1848. He was educated at the college of the Immaculate Conception, Athlone, and at Queen's college, Galway, graduating with honors in 1866. He entered journalism in Dublin the next year, going three years later to London. In 1876, Mr. O'Connor published the first volume of his *Life of Benjamin Disraeli, Earl of Beaconsfield*, but later republished the same under the title *Lord Beaconsfield*, condensing all his material into one volume. It was not flattering to Lord Beaconsfield, and the work made him foes as well as friends. He served for some time as the London correspondent of the *New York Herald*. In 1880, he entered parliament as member for Galway, and was returned for both Galway and Liverpool in 1885. He chose to accept the latter, and has represented one division of that city ever since. In parliament he was one of the most active followers of Mr. Parnell, and out of it one of the executive committee of the Land League. In 1883, he was elected president of the Irish National league of Great Britain. He has edited a *Cabinet of Irish Literature*, and published *The Parnell Movement*. In 1891, he issued a *Life of Charles Parnell*. He traveled extensively in the United States in 1881, lecturing upon Irish politics. Mr. O'Connor is still a member of parliament, late editor of the *London Sun*, and now editor of *M. A. P.* (Mainly about People).

Ocon'to, a town in Wisconsin, on Green bay, at the mouth of the Oconto river. It has large sawmills and a large trade in pine lumber. Population 5,646.

Octa'via, the sister of the Emperor Augustus, was the wife of Mark Antony, whom she married in 40 B. C. to secure his reconciliation to her brother. Though she was noted for her beauty, her noble disposition, and womanly virtues, Antony forsook her in a few years for Cleopatra. In 32 B. C., war broke out between Antony and Augustus, and he sent Octavia a divorce. She showed her noble character by caring for the children of Cleopatra with her own after the death of Antony. She died in 11 B. C. See Shakespeare's *Antony and Cleopatra*.

Octa'vian. See AUGUSTUS.

Octo'ber, from the Latin "octo," meaning eight, was the eighth month of the year at Rome, but became the tenth when Numa changed the beginning of the year to the first of January. There were many attempts made by the Roman senate to change the name.

Oc'topus, also called devilfish, a mollusk related to the squid. It has no shell, either external or internal, and belongs to the class (*Cephalopoda*) called in general cuttlefish. It has eight arms provided with suckers, arranged around a central body. The squid (which see) has ten arms. The body of the octopus is rounded, with large staring eyes, and situated in the center of a membrane which serves to connect the bases of the arms. There are a number of species. They inhabit rocky coasts and feed on mollusks and crus-

OCTOPUS.

tacea. The common octopus of the West Indies and the Mediterranean sea is about nine feet long and weighs about sixty-eight pounds. It is eaten in Mediterranean ports, and the flesh is also used for bait. One species, found on the Pacific coast, is sixteen feet long and has a spread of about twenty-eight feet. The body is so small in comparison to the length of the limbs, that it measures only six inches in diameter and one foot in length. They are naturally timid and have not been known to attack human beings. The lurid description of the devilfish in Victor Hugo's *Toilers of the Sea* is a creation of the fancy.

O'der, one of the main rivers of Germany, rises in Moravia, crosses Silesia, Brandenburg, and Pomerania, finally emptying through three channels into the Baltic sea. It is 550 miles long, but owing to its rapid fall and the sediment left at the mouth of its many tributaries, its navigation is difficult, and great expense is necessary to prevent its overflowing.

Odes'sa, the fourth city in Russia, a seaport of the Black sea, about half way between the Dnieper and Dniester rivers. It is built facing the sea, on cliffs, with deep ravines, and with galleries hollowed out of the soft rock, in which many of the poorest people live. It is a modern city, founded in 1794, near an old Turkish fort, but has grown rapidly, being the chief shipping port for the corn-growing districts of southern Russia. The harbor is protected by moles against the dangerous winds of the Black sea, and is menaced by ice hardly more than a fortnight in the whole year. The trade is largely in

grain, principally wheat, but sugar, wool, and flour are also exported. It also has sugar and oil refineries, and tobacco, leather, soap, and chemicals are manufactured. It has a university with 709 students, a public library, historical museum, cathedral, opera house, and great grain warehouses and elevators. Water is brought to the city from the Dniester river by an aqueduct 27 miles long. Odessa is known as a home of the cholera, and for its persecution of the Jews, and as the headquarters of the nihilists. Population (1897) 405,041.

O'din, the chief god of Scandinavian mythology. He is not the creator of the world, but its ruler, and the ruler of heaven. His home is in Asgard, whence he sends forth daily his two black ravens, Hugin and Munin (Thought and Memory), to bring him news of all that is happening in the world. As god of war he holds his court in Valhalla, where all brave warriors gather after death. He became the wisest of gods by drinking from Mimer's fountain, but at the price of an eye. Frigga is his queen, though he had other wives. His Saxon name, Woden, is perpetuated in our Wednesday, or Woden's day.

Œdipus (*ēd'i-pus*), a hero in Greek legend, whose story is the subject of some of the finest tragedies of Sophocles and Euripides. He was the son of Laius, king of Thebes, who, having learned from an oracle that his own son would kill him, exposed him at his birth with his feet pierced through on Mt. Cithæron. He was discovered by a herdsman of the king of Corinth, named Œdipus from his swollen feet, and brought up by him as his own son. Learning from an oracle that he was to kill his father and marry his mother, he went to Thebes to escape his fate. Drawing near the city, he met the chariot of the king, and was ordered out of the way, which brought on a quarrel in which he slew his father, the king, not knowing him. The Thebans offered the kingdom and the hand of the queen to whoever would deliver them from the Sphinx, who proposed to all who passed her a riddle, putting to death those who could not solve it. Œdipus offered himself, and she asked him, "What being has four feet, two feet, and three feet, and only one voice; but whose feet vary, and when it has the most, is weakest?" Œdipus answered "Man," at which the Sphinx threw herself headlong from the rock where she sat. Œdipus thus became king and the husband of his mother. When a plague devastated the country, the oracle promised relief when the murderer of Laius should be banished, and Œdipus learned from a seer that he had fulfilled the prophecy of the oracle and killed his father, and had for a wife his mother. In horror he put out his eyes, while his mother, Jocasta, hanged herself. He wandered away with his daughter, Antigone, and near Athens was taken from earth by the Eumenides.

Oer'sted, Hans Christian, a distinguished Danish physicist, who first discovered a connection between electricity and magnetism, was born Aug. 14, 1777, and died at Copenhagen, March 9, 1851. He was educated in Copenhagen, where he took his doctor's degree in 1800, and where in 1806 he was appointed to a professorship in physics.

On July 21, 1820, he was passing the current of a large battery through a platinum wire, when he discovered that a magnetic needle near by was deflected. As shown by its consequences, this proved to be an epoch-making discovery, for which the Royal society awarded him the Copley medal and the Paris institute a mathematical prize amounting to 3,000 francs. See AMPÈRE.

Offenbach (*of'fen-bäk'*), **Jacques,** a Franco-Jewish composer, was born at Cologne, Germany, June 21, 1819. He settled at Paris, and became manager in one of the theatres. He composed a great number of operettas, but is best known for a series of burlesque operas, which make him the father of the modern comic opera. The *Grand Duchess*, *The Beautiful Helen*, *Genevieve of Brabant*, *Barbe-bleue*, and *Madame Favart* are among the most notable, the last being very popular in England. He died at Paris, Oct. 5, 1880.

Og'den, a city in Utah, at the union of the Weber and Ogden rivers, where the Weber passes through the Wahsatch mountains. It is situated 37 miles north of Salt Lake City, and is 4,340 feet above the sea. It is a railroad center, and has a Methodist university, a foundry, and several large mills, breweries, and factories. Population 16,313.

Og'densburg, N. Y., a city and port of entry in St. Lawrence county, on the St. Lawrence river, and connected by steam ferry across the St. Lawrence with the Canadian town of Prescott, Ontario. The city lies 175 miles northwest of Albany, and has communication by river westward to the Upper Lakes, and eastward by way of Montreal and Quebec to the Atlantic. By rail, it is served by the Central Vermont, and by the Rome, Waterdown, and Ogdensburg railroads. It has a large grain and lumber trade. Population 12,633.

Oglesby (*ō'g'lz-bi*), **Richard James,** an American soldier and statesman, was born in Oldham county, Ky., July 25, 1824. Being left an orphan at the age of eight years, he found a home at Decatur, Ill., as an apprentice to a carpenter. Working at his trade and studying law until he was twenty years of age, he was licensed in 1845, and began practice at Sullivan. He served as a first-lieutenant in the Mexican war, and at its close, with honor to himself, he returned to the practice of his profession at Decatur. On the discovery of gold in California, he set out for the mines where he remained two years. But

the outbreak of the Civil war found him again at Decatur ready for some new enterprise. He resigned his seat in the state senate, to which he had been elected in 1860, and plunged into the contest, leaving for the front at the head of the Eighth Illinois regiment. He participated in the battles of Ft. Henry and Donnelson, commanding a brigade in each. He was severely wounded at Corinth, but in April, 1863, he returned to duty as a major-general in command of the sixteenth corps. He was elected governor of Illinois and served in that capacity from 1865 to 1869. He was re-elected in 1872, but was chosen United States senator, Jan. 1873. He was governor of the state again from 1885 to 1889, and died at Elkhart, Ill., April 24, 1899.

O'glethorpe, James Edward, an English general and founder of Georgia, was born at London, Dec. 21, 1698. He served in the army, and was thirty years in parliament. He planned a colony in America, as a refuge for debtors, who were then imprisoned in English jails, and also for persecuted German Protestants. George II. gave the land, which was named Georgia after him, and parliament contributed $50,000, and in 1733 he took out 130 persons, and founded the city of Savannah. Another party, including the two Wesleys, went out in 1735, and in 1738 Oglethorpe returned to Georgia with a regiment of 600 men, in anticipation of a war with Spain. He invaded Florida, was unsuccessful in an attack on St. Augustine, but repulsed a Spanish invasion of Georgia. He left the colony in 1743, and surrendered the charter to the British government in 1752. He died in England, Jan. 30, 1785. See *Life*, by Bruce.

O'gowe or **Ogoway,** a river in the western part of Africa, that flows into the Atlantic ocean near Cape Lopez. In the rainy season it is a deep, broad stream, though numerous islands and sand banks prevent large vessels from ascending it. In the dry season it shrinks to a narrow current. The river was discovered by Du Chaillu in 1856.

Ohi'o, a river of the United States, one of the largest branches of the Mississippi. It was named by the French explorers "la Belle Rivière" (the beautiful river). It is formed by the union of the Allegheny and Monongahela rivers at Pittsburg, and flows southwest 975 miles, joining the Mississippi at Cairo, Illinois. It is from 400 to 3,000 feet wide, spreading out so as to become quite shallow in dry seasons. It is subject to floods from the accumulation of snows in the mountains near its headwaters; there is a series of terraces along the banks, which have evidently been the bed of the river. The boundary between the states of Ohio, Indiana, and Illinois, and West Virginia and Kentucky is formed by the Ohio river. At Louisville there are falls, which are passed by means of a ship canal. The river is navigable for its entire length, and carries on its waters enormous fleets of boats, laden with coal, besides other products of the regions.

Ohi'o, one of the north central states of the Union, is the fourth in population. It is nearly square, being 220 miles across from east to west, and 210 miles from north to south; area, 41,060 square miles. Lying between Lake Erie and the Ohio river, with a number of navigable streams, it is well watered and very fertile. It is hilly in parts, but never mountainous, the highest regions reaching an elevation of about 1,500 feet. There are harbors on Lake Erie, the largest at Sandusky bay, which is 18 miles wide, with a group of ten islands covering 2,800 acres, especially devoted to grape-raising. The national government has made improvements in the harbors of Lake Erie, and maintains twenty-nine lighthouses on its coast. The lake fish are a source of wealth to the state, Sandusky being one of the largest fresh-water fish markets in the country. There are two large canals connecting Lake Erie and the Ohio river. The climate of Ohio is very variable, with a large rainfall. In the northern part it is tempered by Lake Erie, so that the region is rich in orchards and vineyards. Ohio has large coal-fields, making it the third coal-producing state; while beds of iron-ore furnish material for its numerous furnaces and rolling-mills. It has large quarries of fine stone for building, and grindstones, and beds of gypsum and rock salt, and numerous salt wells. The petroleum wells are numerous and yield largely, making it second only to Pennsylvania in its oil-products, and natural gas wells supply fuel to many cities and large manufactories. Ohio is the richest state in ancient remains, implements of stone, bone, copper and clay, numerous mounds and extensive earth-works being found there. It is chiefly an agricultural state, raising large crops of corn, wheat, oats, potatoes, and hay, besides producing large quantities of maple sugar, honey, and flaxseed. Its orchards and vineyards are extensive, and it has a large trade in small fruits, and is also one of the first states in its pork products. It is becoming one of the leading manufacturing states, especially in the making of farm implements and all kinds of machinery, carriages, and furniture. It has great foundries and rolling-mills, paper mills, barrel factories, drain and tile factories, match factories, oil refineries, etc.

Ohio is noted for its large number of colleges, there being 34 universities and colleges in the state, besides professional schools, reporting nearly 700 professors and instructors and close upon 9,000 students of both sexes in all departments. As a result of its extensive public school system and these abundant means of higher education its proportion of inhabitants who cannot read is but 4.8 per cent of the population. In 1899, Ohio had 13,077 school buildings, 25,712 teachers, and

an average daily attendance of 613,337 pupils. The State university, with an agricultural experiment station, meteorological and forestry bureau founded in 1862, is at Columbus, the capital; Ohio university, at Athens, was founded in 1804, and given a grant of land when the state was settled in 1787; Oberlin, Kenyon, Miami, Marietta, Antioch, Delaware, Buchtel, and Wooster colleges, Denison university at Granville, Western Reserve university at Cleveland, with the Cleveland college for women connected; Cincinnati university with the Cincinnati observatory as a department, are among the leading institutions; while there are also schools of law, medicine, theology, and science, such as the Case school of science at Cleveland, Lane Theological seminary at Cincinnati, and the medical colleges of Cincinnati, Toledo, and Cleveland.

Ohio was occupied in 1680 by French fur traders, and in 1749 formally taken possession of in the name of Louis XV., leaden plates with records of the act being buried along the Allegheny and Ohio rivers. In 1763, it became a part of the English dominions, and by royal proclamation was set aside for the use of the Indians. Virginia claimed all of Ohio, according to the terms of her charter given by King James, and Connecticut claimed the northern part by her charter from Charles II. New York also claimed it by right of conquest by her Iroquois tribes. These different claims were all yielded at length to the United States government and Ohio became a part of the Northwestern territory. It was first settled permanently in 1788 by what is known as the Ohio company, formed of officers and soldiers of the Revolutionary war, who bought of the nation 1,500,000 acres between the Muskingum and Hocking rivers; and made their first home at Marietta. The second settlement in the same year was made at Cincinnati. For many years emigration to the new territory was checked by Indian wars, until after the battle of Maumee under General Wayne, when the Indians signed the treaty giving up their rights to nearly all of the state, besides parts of Indiana and Michigan. It was organized as a state of the Union in November, 1802. The state has railway lines with a total mileage of 8,920 miles. In 1796, the last buffalo was killed in the Hocking valley, and in 1810 the first steamer crossed Lake Erie, and in 1811 the *Orleans* was the first of the great fleet of steamboats that now run on the Ohio. In the War of 1812, Ohio was invaded by the British, but were repulsed at Fort Meigs, on the Maumee; and in the Civil war it was threatened at Cincinnati by a Confederate army under Gen. Kirby Smith, and "Morgan's Raiders" dashed through fifteen counties on its southern boundary. Population 4,157,545.

Ohio State University, located at Columbus, was organized as "Ohio Agricultural and Mechanical college," and was opened in 1873. By act of legislation, in 1878, the name was changed to "The Ohio State university." The university is maintained by an annual grant from the United States, and permanent annual grants from the state. It comprises colleges of agriculture, of arts, philosophy and science, of engineering, of law, and of veterinary medicine. The university is open to students of both sexes. The instructors number over 100, and the whole number of students is 1,252.

Ohm (*ōm*), **Georg Simon,** a German mathematician and physicist, was born at Erlangen, March 16, 1787, and died at Munich, July 7, 1854. He was educated at the university of his native town where he took his doctor's degree in 1811. In this same institution, he began teaching as a *privat-docent;* but was soon compelled to give this up for a salaried position at Bamberg and subsequently (1817) at Cologne. Ten years later, in 1827, he published his great work on the galvanic circuit, in which he proved the very simple relation existing between current, resistance, and electromotive force, a relation which is now known as "Ohm's Law." For this discovery, Ohm was awarded the Copley medal by the Royal society in 1841. In 1846-49, Kirchhoff extended this law and established two theorems, now known as Kirchhoff's Laws, which include Ohm's Law as a special case. In acoustics, Ohm discovered that the ear of itself analyzes any complex sound into simple tones in the manner contemplated in Fourier's theorem, a fact which proved to be of great importance later in the hands of Helmholtz. In 1852, Ohm was appointed to the chair of physics at the University of Munich. His most important work is, by all odds, his theorem concerning the galvanic circuit.

Oil City, a town in Pennsylvania, lying on both sides of the Allegheny river. It lies 133 miles northeast of Pittsburg, and is in the oil region, and one of the largest oil markets of the state. It has oil refineries, engine and boiler factories, and large manufactories of barrels. Population 13,264.

Oil Wells. See PETRO'LEUM.

Oils, a term used to indicate a large class of compounds. The more common animal and vegetable oils, which are the fatty or fixed oils, are all compounds of glycerine with fatty acids. The term fats is usually given to the solid forms, and oils to the fluid. The solid fats, however, become fluid when heated. All these fats and oils are lighter than water and will not mix with it. They penetrate paper or cloth, making it partly transparent, and leaving what is known as a grease spot. When pure and fresh they usually have little or no taste or smell, but when exposed to the air, become darker in color, have a disagree-

able taste and smell, and are called rancid. As examples of vegetable oils we have cotton-seed oil, linseed oil, olive oil, almond oil, and cocoa butter. Linseed is brought largely from Russia and India; Africa supplies palm oil; India and the Pacific islands cocoanut oil; while the best olive oil is brought from Italy. In animal oils the principal ones are butter, lard, tallow, neatsfoot oil, and sperm oil. Tallow is the fat of oxen and sheep, melted and purified. Lard, obtained from the hog, is one of the great products of the United States, 60,000 tons yearly being sent to Great Britain alone. Neatsfoot oil is produced by boiling the feet of cattle. Sperm oil and other fish oils are obtained from different varieties of fish and sea animals, as the whale, seal, cod, shark, herring, etc. The uses of the different oils are very numerous: as food, and in the preparation of food, in soap making, painting, machinery, and in a thousand other ways they are of great importance. There is a large class of substances known as the essential or volatile oils which resemble the fats somewhat in their properties, particularly in not mixing with water. They make a grease spot on paper which is not permanent. These are quite varied in composition, are more or less volatile and have strong and characteristic odors. Oil of turpentine, of lemon, of wintergreen, are examples of a great number of these products which are largely used as solvents, for flavoring, in perfumery, and in medicine. For mineral oils, see PETROLEUM.

Ojib'ways or **Chip'pewas,** a large tribe of North American Indians belonging to the Algonquin family, and living around the shores of Lake Huron and Lake Superior. They were usually at war with the Sioux and Iroquois, driving the Sioux from the sources of the Mississippi. They sided with the French, taking part in Pontiac's war; and in the Revolutionary war fought with the British. They came as far east as Lake Erie, but gave up all their lands in Ohio in 1817. In 1822, they numbered about 14,000. Their lands have gradually been ceded to the United States, and most of the tribe are on lands west of the Mississippi. Their history has been written by two members of their tribe. See *History of the Ojibway Indians*, by Peter Jones.

Oka', a river in Central Russia, the principal branch of the Volga. It flows northeast through the most fertile region of Russia, for 906 miles, to the Volga. It is navigable for part of the year only.

Okhotsk (*ō-kŏtsk'*), **Sea of,** an arm of the Pacific ocean, on the east coast of Siberia. It is 1,000 miles long, and 600 broad, and contains several islands. It is seldom navigated.

Oklaho'ma, a southwestern territory of the United States. It was a part of the Indian territory. This territory was given to five tribes of Indians from Georgia, Florida, Alabama, and Mississippi. There was more land than they occupied, and in 1866 the United States bought the western part of the territory for the use of the freedmen and Indians. The Oklahoma district, as it was called, covering about 2,000,000 acres, was a part of this purchase. The whites claimed it as public land, but were kept away by United States troops, the Indians claiming that it had been ceded only for the use of Indians and freedmen. In 1889, the government settled these contending claims by paying the Indians another sum of money, and the lands were declared open to settlers, April 22, 1889, and organized as a territory May 2, 1890. No one was allowed to enter the territory until noon, but by night there were 50,000 inhabitants, and the city of Guthrie (now the capital of the state) was built in a day, with 10,000 citizens. Other lands were bought in 1891, making the whole country cover about 28,600 square miles. The name means "beautiful country." It area is 39,030 square miles, divided at first into two parts by a strip of land belonging to the Cherokees, but which was afterward bought by the government. In the south are the Wichita mountains; and the Red river and Arkansas river with their branches furnish water routes. The great plain in the west is a rolling, dry country, covered with sage brush and cactus, but the river valleys are fertile, and much of the country is adapted to growing corn, cotton, and tobacco. A large part of the territory is still occupied by Indians. Population 398,331.

Oklaho'ma City, Okla., a recently settled but growing city, in Oklahoma county, on the North Canadian river; served by the Atchison, Topeka and Santa Fe and the Choctaw, Oklahoma, and the Gulf railroads, 28 miles south of Guthrie. Water-power is here derived from the rapids of the river for the city's industries, which include a cold-storage plant, packing-houses, flour mills, cottongins, brick-yards, grain elevators, etc. It has a considerable trade in lumber and agricultural products. Though founded only in 1889, the city, which has an active rival in Guthrie, has already a population of 10,037.

O'laf, Saint, one of the early Norwegian kings (1015–28 A. D.), was born in 996. He distinguished himself by his warlike expeditions on the coast of Normandy and England. In 1015, he wrested the throne of Norway from Eric and Svend Jarl. His efforts to exterminate paganism by fire and sword lost him the favor of his subjects, who offered their allegiance to Canute, king of Denmark, when he landed in Norway in 1028. Olaf fled to Russia, where he was given a band of 4,000 men, and returning, attacked Canute, but was defeated and slain (1030 A. D.) His body was thought to possess miraculous powers, for which reason he was proclaimed the patron saint of Norway.

Old'castle, Sir John, was born in England in the reign of Edward III. His fame rests upon the fact that he was the first author and the first martyr among the English nobility. He was known as the "good Lord Cobham," a title he acquired by marriage. He became one of Wyclif's followers, and at his own expense had Wyclif's writings copied and scattered among the people, and paid a large body of men to preach the doctrines of the reformer. He took part in presenting a remonstrance to the house of commons against the corruptions of the church. In 1411, he commanded an English army, which forced the Duke of Orleans to raise the siege of Paris. In 1413, he was condemned as a heretic, but escaped and hid four years in Wales. He was captured and brought to London, where he was hanged alive upon the gallows and then burned, in December, 1417. He wrote *Twelve Conclusions addressed to the Parliament of England.* See *Life*, by Maurice.

Old'ham, a manufacturing city in Lancashire, England, 38 miles from Liverpool. It was a small village in 1760, its growth being due to its nearness to the Lancashire coalfields, and its cotton manufactures. It has over 300 mills, and uses one-fifth of all the cotton imported. It also makes hats, velvets, and cords, and has large weaving machine works, one of which employs 7,000 hands. There are public buildings, including a town hall, lyceum, school of science and arts, and public baths; and a fine park. Population about 150,000.

Old Point Com'fort, a village at the mouth of the James river in Virginia. It is the site of Fortress Monroe, and is a famous pleasure resort. Its large hotel, accommodating 1,000 guests, faces Hampton Roads. It was destroyed in 1862, as it was in the way of the batteries on Fortress Monroe, but has been rebuilt and is very popular. The watering place is 13 miles north of Norfolk, Va.

Olean'der, species of Nerium, a genus belonging to the dogbane family. There are but few species, which are natives from the Mediterranean region through southern Asia to Japan. The common oleander of cultivation is *N. oleander*, native to the Mediterranean region; while *N. odorum*, a sweet-scented form, comes from the East Indies. The plant is said to be more or less poisonous, especially the leaves.

O'le Bull. See BULL.

Oleomar'garine, a substance made from tallow, resembling butter. It is also called butterine. The making of artificial butter was first suggested by a French chemist, and is now quite an important industry. The American factories produce large quantities, which is used in this country mostly for cooking purposes, but, shipped to Europe, takes the place of butter with the poorer classes. The beef suet is washed several times in lukewarm water, then minced fine in a cutting machine, and melted by steam, when salt is added. The fat floats on top and is drawn off, purified, and after it is cold, pressed to separate the butter-oil from the stearine. This butter-oil is the true oleomargarine. It is light yellow, and has a pleasant taste. A mixture made of two-thirds of this oil, about one-fifth milk, with a small amount of butter, and some coloring matter, is churned together, the product resembling butter in taste and appearance, and having all the elements that are found in butter made from cream. To prevent its sale as cream-butter, congress has passed a law taxing the sale and requiring every package to be marked as oleomargarine or butterine. The value of the annual product in the United States amounts to nearly $10,000,000.

Ol'ga, St., a Russian princess, and saint of the Greek church. She governed the country during the minority of her son. Going to Constantinople, she was baptized, taking the name of Helena, and labored with great zeal to spread her new faith throughout Russia. She died in 969, and is highly venerated by the Russian church. Her festival occurs July 21.

Ol'iphant, Laurence, an English traveler, author, and religious enthusiast, was born at Cape Town in 1829, but went as a child to Ceylon, where his father had an important government position. He visited Nepaul, an unknown country at that date (1850), and passed through southern Russia and the country of the Crimea, publishing an account of those regions at the outbreak of the Crimean war. Later he became private secretary to Lord Elgin, governor-general of Canada, and subsequently he served as superintendent of Indian affairs in that country. He took a trip throughout the most northern part of our territories, and published a book upon Minnesota in 1855. The earl of Elgin having been sent to China and Japan, Mr. Oliphant accompanied him; and while acting as charge d'affaires in Japan he was badly wounded by a Japanese fanatic, and was obliged to resign his post in the diplomatic service. For some years following (1861) he sat in the English parliament, and contributed to various periodicals, issuing a number of clever and amusing works. But having embraced spiritualism, under the influence of Mr. T. L. Harris, at that time a leader of the cult, he gradually fell into moody and abstracted habits, at last making his home in Haifa, Palestine, from which point he issued a large number of books, now little known. His earliest works were on travel, as *A Journey to Khatmandu*, in 1852. In the seventies he wrote sketches, such as *Piccadilly*, a novel, *Altiora Peto*, a *Narrative of Lord Elgin's Mission to China and Japan*, and in his last years religious works like *Sympneumatæa*, and *Scientific Religion.*

He died at Twickenham, England, Dec. 23, 1888.

Ol'iphant, Mrs. Margaret (Wilson), a Scottish novelist and writer, was born in Midlothian, Scotland, in 1828. Her first book, *Passages in the Life of Mrs. Margaret Maitland*, appeared in 1849, and at once attracted attention. Other works followed, some of them appearing in *Blackwood's Magazine*. Her reputation as a novelist was, however, first made by the publication of *The Chronicles of Carlingford*, running as a serial in *Blackwood's*, from 1861 to 1864, containing some of her best work. She has been a most prolific writer, having written over thirty novels, and ten or twelve other works. Among her contributions to general literature are, *The Makers of Florence; The Makers of Venice; Life of Laurence Oliphant; Life of Edward Irving*, and *Literary History of England from 1790 to 1825*. She edited the series of *Foreign Classics for English Readers*, writing two of them, *Dante* and *Cervantes*, herself. Her home was at Windsor, where she lived many years, having received a pension of $500 from the government in 1868. She died at London, June 25, 1897.

Ol'ive, species of olea, a genus containing over 30 species and natives of the tropical and subtropical regions of the eastern hemisphere. The common commercial species are under cultivation for the well-known fruit. The olive has been cultivated from the earliest times, chiefly for the sake of the oil, which is obtained from the fruit by pressure.

Ol'ives, Mount of, called also "Mount Olivet," lies east of Jerusalem, separated from it by the narrow valley of Jehosaphat. Its name came from a beautiful grove of olive trees, which formerly grew on its western slope, but has now almost disappeared. The brook Kedron flows through the valley, and by the bridge crossing it is the Garden of Gethsemane. The mount is divided into three summits, the highest 361 feet above Jerusalem, and 2,725 above the sea, and on the central summit is the village of Olivet. The northern peak is supposed to be the place where the angels appeared to the disciples after the resurrection of Christ, and was the site of the Roman encampment at the destruction of Jerusalem. The central peak is pointed out as the mount from which Christ descended, after his resurrection, the place where he wept over Jerusalem, and where he taught his disciples the Lord's Prayer. St. Helena built a church here, the site of which is now occupied by a later one, called the Church of the Ascension, and near it is a Mohammedan mosque.

Olm'sted, Fredrick Law, an American landscape-gardener, was born at Hartford, Conn., April 26, 1822. He studied engineering at Yale, and followed farming and gardening for a few years. Becoming interested in landscape-gardening, he traveled on foot through England in 1850, and in 1855 through France, Italy, and Germany, to study the parks and ornamental grounds of those countries. He published *Walks and Talks of a Farmer in England*, *A Journey in the Slave States*, *A Journey Through Texas*, and *A Journey in the Back Country*, after a tour through the south and west. He is best known as the superintendent, with Mr. Vaux, of the laying out of Central Park, New York, and also of the grounds around the capitol at Washington. He has also designed parks and public works at Chicago, Buffalo, Brooklyn, Boston, Milwaukee, and Montreal, and acted as commissioner of the national park of the Yosemite. He also planned the laying out of Jackson Park, Chicago, for the Columbian exposition. He was appointed by Lincoln on the commission to inquire into the sanitary condition of the United States army, serving on it three years (1861–63).

Ol'ney, Richard, an American jurist and statesman, was born at Oxford, Mass., Sept. 15, 1835. He graduated from Brown university in 1856, and afterward spent three years in the Harvard College Law school. Being admitted to the bar he began the practice of law at Boston and rapidly rose to fame. He took no active part in politics until, during the administration of President Cleveland, he was called to a place in his cabinet as attorney-general, and afterward as secretary of state. On the return of the Republicans to power he resumed the practice of law at Boston, having won distinction in the settlement of various important matters of state upon which he was called to act during his career in the cabinet.

RICHARD OLNEY.

Olym'pia, the capital of Washington, is built on a peninsula at the southern end of Puget sound, 65 miles from the Pacific ocean. The Des Chutes river, which enters Puget sound here, has a fall of 85 feet in 300 yards, which gives abundant water-power. There is a bridge, 2,030 feet long, across the end of the sound. The Coast mountains on the left and the Cascade mountains on the right, with the sound in front, make the scenery very fine. There are flour mills, sawmills, shoe and soap factories, and some good public buildings. Population 4,082.

Olym'pic Games, the most famous and splendid national festival of the Greeks, celebrated once in five years in honor of their

god Zeus, on the plain of Olympia. Olympia was a beautiful valley near the river Alpheus, and contained temples, monuments, altars, and statues, connected with Greek art and religion. There were about 3,000 statues here at the time of the elder Pliny (23–70 A. D.). The sacred grove was a level space, nearly square, being 600 feet long and about 580 feet broad. It looked toward the Ionian sea, with the rivers Alpheus and Cladeus on its southern and western boundaries. It was well-wooded and crossed by a road called the Pompic Way, the route taken by all the processions. The games date back of the year 776 B. C., but in that year became a national festival, and the custom of reckoning time by Olympiads began. The contests were at first permitted only among the Greeks, but after the Romans conquered Greece they took part in the games, Tiberius and Nero appearing in the list of victors. Women were not allowed to be present, with the exception of the priestess Demeter. The games were held at the time of the first full moon of the summer solstice, about the last of June. While the games were in progress, all hostilities were stopped by proclamation of heralds through the country. The contestants went through a ten months' training in the gymnasium at Elis, and the judges, at first two, but later twelve in number, were instructed as long in their duties. The judges held office only one year. The contests were foot-races, wrestling, boxing, leaping, running, throwing the spear and the discus, or quoits, with chariot and horse races. The fifth day there were processions, sacrifices, and banquets to the victors. The victors, each holding a palm branch, were presented to the people, and while heralds proclaimed their names and their parents', they were crowned with garlands of wild olive twigs, cut from a sacred tree of the grove. Statues were erected to them; they had the place of honor on public occasions, were usually exempt from paying taxes, and at Athens were boarded at the expense of the state. Songs were sung in their praise, as fourteen of Pindar's lyrics bear witness. The games were abolished by the Emperor Theodosius in 394 A. D.

Olym'pus, Mount, a group of mountains in Turkey between Thessaly and Macedonia. The eastern side fronts the sea, and has deep precipices and ravines filled with forest trees. The highest peak is 9,790 feet high. In Greek mythology it was the residence of Zeus, whose palace was thought to stand on its summit.

O'maha, the largest city of Nebraska, capital of Douglas county, is on the Missouri river, which is crossed by a railroad bridge 2,750 feet long. The city is built on a plain 80 feet above the river, which rises gradually into bluffs. The business portion of the city is on the level portion, while the bluffs are occupied by the tasteful homes of the citizens. The city hall, United States courthouse, chamber of commerce, state asylum for the deaf, Creighton college, a medical college, and over 100 churches are among its prominent buildings. The *Omaha Daily Bee* is the most important newspaper published between San Francisco and Chicago. Omaha ranks with Chicago and Kansas City as a live-stock market, having immense stockyards, which cover over 200 acres of land, and also large beef and pork-packing establishments, being the third city in the United States in the value of its pork products. The manufactures include linseed oil, boilers, safes, bags, soap, and beer. The largest silver smelting works in the world, using one-fourth of the silver ore mined in the United States, are located at Omaha. The military department of the Platte, covering 82½ acres, with fine barracks, is near the city. The public schools of Omaha are maintained at an annual cost of $450,000; the teaching force numbers 412, and there are 20,617 pupils in attendance. Omaha was founded in 1854, and rapidly became one of the leading western cities. Population 102,555.

O'mahas, a tribe of American Indians, of the Dakotah family, settled in northern Nebraska. They were found by Marquette (1673), by Carver (1766), and by Lewis and Clarke (1805). They were constantly at war with the Sioux, but since 1855 have been at peace and have improved rapidly. They cultivate the ground, and have churches and schools.

O'mar I., Abu Hafsah Ibn ul Khattab, the second caliph of the Mussulmans, was born about 581 A. D. Although he was at first bitterly opposed to Mohammed, he suddenly gave his adherence to the cause of the Prophet and became a chief supporter of his creed and claims. He succeeded Abu-bekir in 634 A. D. He declined the title "Caliph," Successor, as too exalted; and chose rather to be called "Emir," Commander. It was through his command the Hejeira (Flight) was adopted as the point from which the followers of Mohammed should date their years. It was by his genius that the Arabian Empire was founded. Under his irresistible advance, Syria and Palestine were conquered, and he built the Mosque of Omar which still stands central in Jerusalem. He subdued Egypt and Persia, and brought for the first time all the Arabian tribes under one creed and authority. An act of injustice, not usual with him, it should be said, incurred the resentment of a Persian slave, and he was assassinated 644. He was buried near Mohammed.

O'mar Khayyam (*khī-yam'*), a Persian poet and astronomer, was born at Nishapur, in Persia, about the middle of the 11th century. Khayyam is his poetical name, and was taken from his father's business as a tent-maker. He was educated under one of the great Persian teachers, and offered a place at court, but refused, and was given a

pension instead. He reconstructed the calendar, making it, as Gibbon says, "very much superior to the Julian, approaching in accuracy to the Gregorian style." He wrote mathematical treatises in Arabic, one on algebra, which has been translated into French. He was better known as an astronomer than as a poet, until 1859, when Edward Fitzgerald, published a translation of his *Rubáiydt* or quatrains, which gave him a place among the true poets, though the translation is deemed much finer than the original. His astronomical work brought on him the suspicion of heresy, which his poem did not remove, and to allay the feeling against him he made a pilgrimage to Mecca. He died at Nishapur in 1122. See *Letters and Literary Remains of Fitzgerald*, Vol. III.; *Rubáiydt.*

O'mer Pasha (*pash'ä*), was born at Plaski, in Croatia, a province of Austria, in 1806. His real name was Michael Lattas. He fled, in fear of punishment, from the Austrian army to Bosnia. Here he became a Mohammedan, and was made writing-master to Abdul Medjid, then heir to the Turkish throne. When Medjid became sultan, he made Omar Pasha governor of Lebanon. When the Russians invaded the European dominions of Turkey, he was sent with an army of 60,000 men against them, and successfully withstood them at Kalafat, and after their withdrawal from the country entered Bucharest in triumph, August, 1854. He embarked for the Crimea in 1855, and defeated 40,000 Russians at Eupatoria. He was sent to Bosnia and Herzegovina when in insurrection, September, 1861, and after settling their difficulties he attacked Montenegro, capturing the city Cetinjé; and in 1867 he led a command against the insurgents in Crete. He was governor-general of Bagdad, and also minister of war from Bagdad at different periods. He died at Constantinople, April 18, 1871.

On'ega, Lake, in the north of Russia, northeast of Lake Ladoga, and after it the largest lake in Europe. It is 146 miles long and 50 miles wide, covering 3,764 square miles. It has but one outlet, the river Svir, flowing into Lake Ladoga. There are numerous islands and bays, and abundance of fish. It is closed by ice for 156 days in the year, but has a large traffic on its waters at other times. A ship canal, 145 miles long, to connect it with the White sea, is planned, the surveys being finished in 1890.

Onei'da, Lake, one of the numerous lakes of central New York. It is 23 miles long and about 5 miles wide, and flows through the Oneida river into the Oswego river. It lies 11 miles northeast of Syracuse.

Onta'rio is the wealthiest and most prosperous province of the Canadian Dominion. Its distinguishing natural features are the Great Lakes (Superior, Huron, Erie, and Ontario), which wash its shores, and the river St. Lawrence, the great highway of its commerce to the sea. The river Niagara forms part of the water system of the province, connecting Lakes Erie and Ontario. About midway in its course it is broken by the well-known falls of that name; but by means of the Welland canal communication between the two lakes is practicable for vessels of considerable burden. Of recent years, the magnificent water-power of the Niagara Falls and of the Lachine Rapids in the St. Lawrence has been utilized for electrical purposes and to furnish water-power for many important manufacturing industries. As features of striking interest in the physical geography of the province, it may be stated that the surrounding Great Lakes, although they are at four diverse levels, in reality occupy only two distinct stages, separated by the Niagara Falls. This will be seen when we state that below the cataract is Lake Ontario, 247 feet above the sea; above it are Lakes Erie (573 feet), Huron and Michigan (581 feet), and Superior (602 feet). The other important lakes within the province are Nipissing, Nipigon, Simcoe, the Rideau lakes, the Muskoka chain, and, at the western end of the province, Lake of the Woods. The total area of Ontario is 222,000 square miles. The population, in 1901, was 2,167,978. Its chief cities are Toronto, on Lake Ontario, the provincial capital and seat of the Ontario government (population 207,971); Ottawa, on the river of the same name, the administrative capital of Canada and the meeting place of the Dominion Parliament (population 59,902); London (population 37,983); Hamilton (population 52,550); Kingston (population 18,043); and Brantford (population 16,631).

A hundred years ago, the whole of what is now called Ontario (formerly known as Upper Canada) was a forest wilderness, and its capital, in early days designated "Little York," was unknown, save as a small French trading post. In 1793, its foundations were laid by Governor Simcoe, the first administrator of the province, who also made it the provincial capital. In 1834, it was incorporated as a city, when it assumed the Indian appellation which it now bears,—namely, Toronto. To it the rich province of Ontario, with not a little of the vast northwest, is tributary. Besides being the seat of the provincial legislature, it is the seat of the law courts and universities, and the chief home of industry and commerce. Here are many of the higher educational institutions of Canada, including the University of Toronto, with 1,300 students; the university of Trinity college; Victoria and McMaster universities; Wycliffe, Knox, and St. Michael's colleges; Upper Canada college, and the school of practical science. Several other towns of note in Ontario have, besides their thriving industries, interesting social centers, important seats of learning. One of these is Kingston, with its university of Queen's college, under its enthusiastic and learned principal, the

Very Rev. George M. Grant, D.D.; another is Ottawa, with its University of Ottawa. There are also colleges at Woodstock and at Sandwich; ladies' colleges at Hamilton, London, Brantford, Whitby, Oshawa, and St. Thomas; and the Ontario Agricultural college at Guelph. As the older part of the province is now largely intersected by railways, manufactures have arisen and have been given a great impetus, while denser settlement has been facilitated. But that section of the province, from the Ottawa to the Detroit rivers, and from Lakes Erie and Ontario to Lake Huron and the Georgian bay, is not now all of Ontario, though it is its chief cultivated and populated area. It extends far northward and westward, along the line of the Canadian Pacific railway — the north shore of the Great Lakes to the Lake of the Woods, its northwestern frontier, adjoining the province of Manitoba; while its northern boundary is James bay, and its northwestern the Albany river. In these higher latitudes, the climate of the province is in winter severe, with the thermometer not infrequently falling to 40 degrees, and even to 50 degrees below zero. In the more settled peninsula, however, the winters are much milder, and the summers are seldom oppressively hot, the tempering influence of the lakes modifying the heat and making the season delightful.

Onta'rio, Lake, one of the five Great Lakes of North America. It lies between the Canadian province of Ontario on the north and New York state on the south, and has an elevation of 250 feet above the sea. It is the smallest of the group, covering 7,240 square miles, and being 190 miles long and 55 miles wide. It forms the connection between the Niagara river and the St. Lawrence. The level of its waters varies about three and a half feet at regular periods, of from four to seven years, which it is thought may be due to an underground river. The Welland canal connects it with Lake Erie, the Oswego canal with the Erie canal and Hudson river, and the Rideau canal with Ottawa. It is subject to storms, the agitation of its waters by which, may account for its seldom freezing, except along the shore.

On'yx. See MARBLE.

Oogonium (*ō'ō-gō'nĭ-ŭm*) (in plants), the female organ in thallophytes. It consists usually of a single cell, which produces a solitary egg, the oosphere. It may be a special cell set apart for this purpose from its beginning; or it may be an ordinary nutritive cell, which later becomes modified into an egg-producing cell. See THALLOPHYTES.

Oosphere (*ō'ō-sfēr*), the general name for the female sex cell or egg in plants. See EGG.

O'ospore (in plants), the general name for the spore which results from the fertilization of an egg by a sperm. The oospore is sometimes called a "fertilized egg," and in plants which have a distinct alternation of generations, the oospore in germination always produces the sporophyte.

O'pal is a mineral, something like quartz, composed mainly of silica and water. It is never found in crystals, and is very easily broken. There are many kinds, so nearly resembling each other as to be with difficulty distinguished. The finest kind, known as precious opal, noble opal, or oriental opal, is partially transparent, and of a bluish or yellowish white, with a beautiful play of brilliant colors produced by small fissures which refract the light. It is never cut in facets, as diamonds are, because its play of colors is better on a convex surface. It is used in jewelry. The ancients valued the opal very highly, the Roman senator Nonius preferring exile to giving up an opal to Mark Antony. This was valued at $500,000. The most celebrated opal now known belongs to the imperial jewels at Vienna, and is five inches by two and a half inches in size. The finest opals are brought from Hungary, and are usually very small, but even a small one, if perfect, is worth twenty or twenty-five dollars. Opal is also found in Saxony and in South America. The common opal is white, yellow, green, red, or brown, but without any play of colors. It is not at all rare, occurring in veins and holes in rocks. Wood opal is wood turned into opal, the mineral having taken the place of the woody structure.

Op'era is a drama which is sung, accompanied by a full orchestra, or chorus of musical instruments. It makes use of the aria or song, duets, trios, the recitative or declamation, instrumental interludes, or whatever the situation requires. The introduction or opening is called an overture. There are three chief classes or schools, the Italian, the German, and the French. The Italian opera is the earliest, dating as early as 1600, and is noted for its melody. Scarlatti (1659–1725) may be considered its founder. The most famous modern Italian composer is Rossini, his *Barber of Seville* and *William Tell* both retaining a place on the modern stage. Bellini, Donizetti, and Verdi are other well-known composers of this school.

The early opera in Germany was Italian, Dresden and Vienna being the centers. The national school was founded at Hamburg by Keyser, who wrote more than 100 operas (1694–1734). Mozart's first work was Italian in form, though surpassing them in their own field; but his *Magic Flute* was the first national romantic opera. Beethoven composed but one opera, *Fidelio*, while Weber used the national folklore in his *Der Frieschütz* (Free Archer) with great effect. Melodrama originated in Germany. The singer recites his part in a speaking voice, while the music of the orchestra seeks to give the meaning of the scene to the audience.

The French grand opera school was founded by a Florentine, Sully, and reformed by the

German composer, Gluck, while Cherubini, Rossini, Myerbeer, and Wagner were foreigners who aided in its development. The French school paid particular attention to rhetoric, and the use of the recitative or recitation has always been prominent. Italian opera became the fashion in London from the time of Handel, and was introduced into America in 1825. See *Memoirs of the Opera*, by Hogarth; *Essays on Modern Opera*, by Edwards.

Op'era Glass, an instrument for making distant objects appear brighter and more distinct. An ordinary opera glass is essentially two telescopes, of the type employed by Galileo, mounted in one frame so as to produce two images of the same size, one for each eye. The principle of the opera glass is therefore exactly the same as that of the astronomical telescope, except that the latter uses a converging eyepiece, while in the opera glass a diverging eyepiece is used. The reason for this difference is twofold, namely, the diverging eyepiece gives an upright image and the total length of the opera glass is the difference between the focal lengths of the object lens and the eye lens. This makes the opera glass short, so that it can be easily carried in the pocket. If a converging eyepiece were used, the distance between the objective and the eye lens would have to be equivalent to the *sum* of their focal lengths, which would make

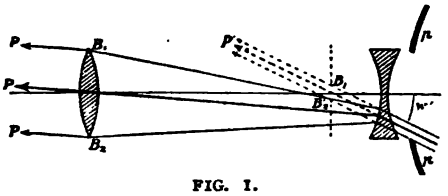

FIG. 1.

the instrument unwieldy. The optical behavior of the opera glass will be clear from the accompanying figure, where B_1 B_2 indicates the object glass, through which pass three rays from a very distant object P. The pupil of the eye is indicated by p p, and the image of P is seen erect in the direction indicated by the three rays P_1. The principal focus of either lens falls at some point within the eye. Note that the angle which the image subtends at the eye is very much greater than that under which the object is seen with the naked eye.

Zeiss of Jena has recently introduced an enormous improvement into the ordinary opera glass, by using (instead of two Galilean telescopes) a pair of astronomical telescopes. But he avoids the difficulty of extreme length, mentioned above, by placing between the two lenses a pair of prisms such as is shown in the accompanying figure. The path of the ray between the two lenses is thus doubled upon itself, securing a short length for the instrument and at the same time giving an erect image, and a large, clear field.

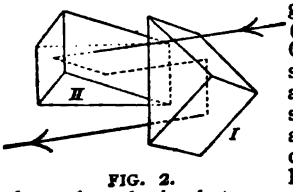

FIG. 2.

These prisms allow him also to place the two objectives a foot or so apart, while the eye lenses are at a distance suited to the eyes.

Equipped with such a glass, a field officer can stand behind a tree in safety while he is watching the operations of the enemy. It need hardly be added that the armies and navies of all civilized countries are now furnished with these glasses.

Ophir (*ō'fẽr*), a place mentioned in the Bible, from which the navy of Solomon brought gold, precious stones, sandalwood, etc. The voyage took three years. It was either on the eastern coast of Africa, in Arabia, or in India, but in which of the three countries is doubtful. Josephus places it on the peninsula of Malacca.

O'pie, John, an English painter, was born at Cornwall, England, in May, 1761. His attempts at portrait painting secured him the help of "Peter Pindar" (Dr. Wolcot), who took him to London, where he was known as the "Cornish wonder." His *Murder of Rizzio*, *Jephtha's Vow*, *Presentation in the Temple*, and *Juliet in the Garden* are his most noted works. He illustrated Boydell's *Shakespeare*, Macklin's *Poets* and *Biblical Gallery*. He also wrote the *Life of Reynolds*, and lectured on art. He died at London, April 9, 1807.

O'pium is the dried juice of the unripe seed vessels of a kind of poppy. The poppy is cultivated in India, Persia, and China, as well as in Turkey and in Egypt. It requires a very rich soil, and irrigation is often used as an aid to its cultivation. The main opium district in India is a large tract on the Ganges, about 600 miles long and 200 broad. In India the seed is sown in November, the plant blossoms in January or later, and in three or four weeks after, when the poppy heads or capsules are about as large as a hen's egg, the field is ready for work. The collector takes a small instrument made of four little knives tied together, looking like the teeth of a comb, and with this cuts or scratches the poppy heads. This is done in the afternoon, and the next morning a milky sap can be collected from the heads by scraping with a kind of scoop into an earthen vessel. The vessel is kept turned on its side so that any watery fluid may drain out, and as the juice dries it is turned often, so that it will dry equally. It takes three or four weeks before it is thick enough to be used in the factories. It is then thrown into great vats in the factories and kneaded, and made into balls or cakes, which are dried and packed in chests for the market. Opium has a bitter taste and a peculiar, heavy odor. It is poisonous, but makes a most

valuable medicine, in which form it is used to allay pain and produce sleep. The habitual use of the drug is known as opium-eating or the opium habit, and is made use of to relieve pain or sleeplessness, when it soon becomes a habit most difficult to overcome. The amount usually taken is about three grains a day, though De Quincey (himself a slave to the habit) says that he used sometimes 8,000 drops of laudanum (a form of opium) daily. It acts as a stimulant, followed by feelings of depression and nervousness, requiring a fresh dose to remove them. Another way in which it is used is in smoking, a practice most common in China and in India. The opium prepared for smoking is called "chandu," and is a watery extract about twice as strong as the drug. A piece of opium as large as a pea is placed in a small cup at the end of a pipe and lighted, and the smoke inhaled. The opium is distilled by the process, and there is very little morphine in the smoke. There are said to be a million opium smokers in the United States. Its excessive use wrecks the constitution and seems to destroy also the moral faculties. For the opium wars, see CHINA. See *Opium and the Opium Appetite*, by Calkin; *Opium Smoking in America and China.*

Oporto (*ō-pōr'tō*), the second city in Portugal, is situated on the Douro river, three miles from the Atlantic shore. The city climbs the steep banks of the river, its houses, gayly painted, making a bright picture set off from the pine-covered mountains behind it. On one of the crags overlooking the river is a crystal palace surrounded with gardens. The old cathedral was built by Henry the Navigator; the old Gothic church was founded in 559, and the former monasteries are used, one as a citadel, one as an exchange, and one as barracks. There is a medical school, observatory, art academy, library of 250,000 volumes, and two picture galleries. The railroad to Lisbon crosses the river a little above the city on one of the finest arch bridges built. The manufactures are of cloth, silk, hats, porcelain, ribbons, tobacco, soap, and metal casting; distilling, cork cutting, and sugar refining are among the industries. It is the chief seat of the export trade in port wine. Oporto was the stronghold of the Christians in the peninsula against the attacks of the Moors. The people opposed the usurper, Miguel, in 1828, who executed many of them; but they supported Pedro of Brazil, and withstood the besiegers thirteen months. Population 138,860.

Opos'sum, the name given to a number of animals representing the marsupials, or pouched animals, in the New World. There are some sixteen species, varyingin size from a cat down to a mouse. Some are provided with pouches on the under side of the body in which the young are reared, and others have no sign of a pouch. The Virginia opossum is common from the central United States to Brazil. It is one of the largest members of the group, being about the size of a cat. The fur is dirty yellow, the ears and feet are black, and the tail is scaly and used for grasping. This form has a well-developed pouch. The young, often to the number of thirteen, are born in a helpless condition, and, with the help of the mother, are attached to the breasts — which number thirteen — covered by the pouch. They live on trees and are active mainly at night. They feed on insects, small reptiles, eggs, and the like. Their habit of feigning death when frightened or slightly injured is well known. They get very fat, and are highly esteemed as food by the colored people. There are a number of species in South America. In those forms without a pouch, the young, when fully developed, are frequently carried on the back, with their tails twined around that of the mother.

OPOSSUM.

Op'tics. See LIGHT, TELESCOPE, CAMERA, EYE, OPERA GLASS, MICROSCOPE, PHYSICS.

Or'acle, the name given in ancient times to a revelation made by some god in answer to questions, and also to the place where the revelations were given. The revelations were usually made by the mouths of priests or priestesses, and sometimes by other signs. At Dodona, the oracle answered by the motion of leaves, or the murmuring of the waters of a fountain, and the oracle of Ammon responded by the shaking of the statue of the god. The Egyptian temples were nearly all oracles, and there were oracles among the Babylonians and Phœnicians. The most famous oracle of the Greeks was the one at Delphi. The inquirers offered sacrifices, walked around the oracle with laurel crowns on their heads, and inscribed their questions on leaden tablets, many of which have been discovered. The answer was accepted as final and having authority, and usually was just and reasonable. Other oracles were at Ismenus, Delos, and Olympia. See *Greek Oracles*, by F. W. H. Myers; *Religious Antiquities*, by Schomanns (translated).

Oran (*o-ran'*), a city in Algeria, is situated on the gulf of Oran, 260 miles southwest of Algiers. The harbor is protected by moles, built in 1880. The city lies at the foot of a hill, defended by forts, and has two citadels. There is a Roman Catholic cathedral, a Mohammedan mosque, a military hospital, a college, and a seminary. The principal exports are alfa, iron-ore, and grain. The city

was founded by the Moors, and in the 15th century was very prosperous. It was famed for its cloth and arms, as well as for its fine public buildings. In 1509, the Spaniards, after taking it, made a penal settlement of it. Captured by the Turks in 1708, it was retaken by the Spaniards in 1732, who abandoned it in 1790, after it was almost destroyed by an earthquake. The French took possession of it in 1831. Population 85,801. Oran is also a department in Algeria, area 44,616 square miles, with a population, embracing both the military and the civil territory, of 1,028,248.

Or'ange, the fruit of *Citrus aurantium* and its varieties. To the same genus belong the limes, citrons, grape fruits, etc. All the species of the genus are natives of tropical and subtropical Asia, but are now extensively cultivated throughout the warmer regions of the world. In the United States, the orange cultivation centers in Florida and California. There are numerous cultivated forms, the so-called "navel oranges" being an accidental variation. Among the commoner forms are the common sweet orange, a native of India, among whose most prized cultural forms are the Washington navel and Riverside navel; and the mandarin or kid-glove orange, a native of China, various cultivated forms being known as mandarins and tangerines.

Or'ange, a city of Essex county, N. J., twelve miles west of New York. The name includes also parts of the townships of East Orange, West Orange, and South Orange, which are all suburbs of New York, often called the Oranges. The region around the city is laid out in beautiful parks, with elegant homes, rising above each other, ending in a broad crest on the top of Orange mountain, 650 feet in height. Llewellyn park, of 50 acres, is on the eastern slope of the mountain. The city has manufactures of hats and shoes, and in the northern part is the beautiful Rosedale cemetery of 50 acres. At South Orange is a Roman Catholic college and Theological seminary. Population (of the city) 24,141.

Or'ange River, the largest stream in South Africa, flowing west into the Atlantic ocean. It is 1,000 miles long, but is navigable only in the rainy season, and its mouth is obstructed by a bar.

Or'ange River Colony. This British possession in South Africa, after having existed for 46 years as an independent republic, under the name of the Orange Free State, was, after military occupation by the British forces, in consequence of the Boer war, annexed by proclamation May 4, 1900, and is now known as the Orange River Colony. The area of the colony is about 48,326 square miles, the total population being, in 1890, natives included, 207,500. Of this number, about 80,000 were white, who chiefly engaged in agriculture, and in the raising of sheep, cattle, horses, goats, ostriches. This population is chiefly of Dutch origin. The colony was founded by the Boers who trekked from Cape Colony in and after 1836, and was declared independent in 1854. It lies between the Vaal and the Orange rivers, on a plain rising from 3,000 to 5,000 feet elevation, with bluffs or slopes toward the rivers that border it, and dotted with kopjies, or flat-topped hills. The prevailing religion is that of the Dutch Reformed church; while the Roman Dutch law has hitherto been in use. Bloemfontein is the capital, with a present population of about 4,000. The undulating plains of the interior here afford excellent grazing. The colony is known to be rich in coal-mines; while in and on the borders are valuable diamond mines, the yield from which, as well as from garnets and other precious stones, has been phenomenally large. A railway, constructed by the Cape Colonial government, connects the Orange river (at Norval's Point) with the capital, as well as with the Transvaal, lying to the north of it. The length of the railway lines in the colony is about 400 miles. There are 1,500 miles of telegraph lines in the colony, giving communication with Cape Colony, Natal, the Transvaal colony, and Basutoland. See the TRANSVAAL, also CAPE COLONY, and the BOER WAR, in this *Cyclopædia.*

Orang-outang (*ō-rang'ō-tang'*), one of the higher apes found in the swampy forests of Borneo and Sumatra. With the chimpanzee and the gorilla, they approach closely to man in structure. A full-grown male reaches a height of four feet and four inches, but the outstretched arms cover seven feet eight inches. The body is bulky and covered with long, reddish-brown hair. The legs are short, but the arms are so long as to reach the ankles when the animal is erect, and, in walking, the knuckles are placed on the ground. Thy are, however, awkward on the ground and prefer the trees, where they can travel five or six miles an hour, without especial effort, by swinging along on the branches, which they grasp mainly with their hands. They feed on fruits and succulent shoots. They retire to rest at sundown in nests made of broken boughs, and placed twenty or thirty feet above the ground. In captivity they are not so active and intelligent as the chimpanzee. See APE.

ORANG-OUTANG.

Orato'rio, a sacred story set to music, and accompanied, as in the opera, with a chorus

and orchestra or band of musical instruments, but without the use of scenery or costumes or acting. Its name is derived from the oratory of the Church of Santa Maria Maggiore near Rome, where, from 1571 to 1594, musical performances of this class were first arranged. The oratorio was produced in Rome in 1600, the same year in which the first opera was given in Florence. The first development of the oratorio had the passion of Christ for its subject, and the greatest passion music is the *St. Matthew*, written for service on Good Friday, by Sebastian Bach, in 1729. The next form was the "epic," used by Handel in fifteen grand oratorios, the greatest of which are *Israel in Egypt*, and the *Messiah*, and by Haydn in his *Creation*, and Mendelssohn in *Elijah*. The modern oratorio uses more of the dramatic element, and inclines to the form of a cantata, of which Liszt's *St. Elisabeth*, and Schumann's *Paradise and the Peri*, are fine examples. See *Standard Oratorios*, by Upton.

Orcagna (*or-kän'yä*), **Andrea di Cione,** an Italian painter, sculptor, architect, and poet. He was nicknamed "Arcagnuolo" (archangel), of which Orcagna is a corruption. He was born about 1316, at Florence, his father being a sculptor and worker in silver and his elder brother a painter. He was appointed architect of the Church of San Michel at Florence, in 1335, and his greatest work is the marble tabernacle of this church, which is considered one of the most beautiful art-creations of Italy. He was also chief architect of the cathedral at Orvieto. The frescoes of the *Last Judgment* and *Christ and the Virgin*, in the Church of Santa Maria, at Florence, still survive as examples of his painting. His work was studied by succeeding painters, especially by Michael Angelo and Raphael. He died about 1376. See *Painting in Italy*, by Crowe and Cavalcaselle.

Or'chardson, William Quiller, R. A., a Scotch painter, was born in 1835, at Edinburgh, where he studied art. He is considered to belong to the first rank of genre painters, that is, a class of paintings whose subjects are taken from everyday life. His pictures, many of the later of which are fashionable interiors, and portraits are very popular and exquisitely finished. Among the best known are, *The Challenge*, *The Bill of Sale*, *Hard Hit*, *After*, *The Salon of Madame Récamier*, *The Rift within the Lute*, *Her Mother's Voice*, and *The Young Duke*.

Orchids (*ôr'kĭds*), species of a great monocotyledonous family, the *Orchidaceæ*, containing over 6,000 species. Their greatest display is in the tropics, where many of them are brilliantly colored epiphytes. There are many beautiful species, however, in the temperate regions, chiefly in bogs. The flowers are very much modified, always having a conspicuous spur, at the bottom of which nectar is secreted. Among the best known forms are the common lady-slippers or moccasin flowers (*Cypripedium*), in which the spur is

LADY-SLIPPER.

replaced by a conspicuous sac, the so-called "slipper" or "moccasin." Orchids are very highly specialized in reference to pollination by insects. Each kind of orchid has its own kind of insect, and all of the elaboration of the flower is connected with this fact. In greenhouses, orchids are among the most prized of plants, on account of the showy colors and the strange forms of the flowers, the most conspicuous being the epiphytes from the tropical forests. See *Orchids, their Culture and Management*, by Watson.

Ord, Edward Otho Cresap, an American general, was born in Cumberland, Md., Oct. 18, 1818. He served in the Seminole war in Florida, and on the frontiers, until the beginning of the Civil war, when he became brigadier-general of volunteers, and was given command of Pennsylvania reserves, and gained the battle of Dranesville (December, 1861). In May, 1862, as major-general of volunteers, he was given a command in the department of the Mississippi, and took part in the battle of Iuka and the capture of Vicksburg. In 1865, he was in command of the army of the James, and the department of Virginia, and was in the battles that ended the war. After the war he became a brigadier-general in the regular army, had command of various departments, and retired in 1881 with the rank of major-general. He died at Havana, Cuba, July 22, 1883.

Or'egon, one of the Pacific states of the Union, and the twentieth admitted (Feb. 14, 1859). It is divided into two unequal parts by the Cascade mountains, which are about 130 miles from the coast, while the coast range is within 25 miles of the Pacific shore. The Cascade range rises 6,000 or 8,000 feet with high peaks, among them Mt. Hood (11,225), Mt. Jefferson (10,200), Mt. Pitt (9,818), all being extinct volcanoes. On the

east are the Blue mountains and Powder river mountains, from 8,000 to 10,000 feet high. The state is 360 miles broad and 270 miles long; its area is 96,030 square miles, and is almost twice as large as New York state. The capital is Salem (population 4,258) and the chief cities are Portland (population 90,426), Astoria, and Baker City. There are 330 miles of coast, with a narrow strip of land and several fertile valleys. The part of the state west of the Cascade range is the most valuable, two-thirds of it being occupied by the Willamette valley, which is rich in farms and villages, where the crops never fail, and where half of the population and the wealth of the state are found. The eastern part of the state is very varied, having pasture lands and grazing grounds in the north, and in the south the Great Basin, an arid region larger than France, requiring irrigation to make it productive. Great beds of lava, plains covered with sage brush, rivers sinking away into shallow lakes or marshes, and brackish lakes in which fish cannot live are the features of this region, which is crossed by the Stein mountains. Crater lake, in the southwest of Oregon, is one of the deepest fresh-water lakes in the world, and is formed by the snows filling an extinct crater. In the center rises Wizard island, 845 feet high, with an extinct crater at the top. A large area, including this lake, has been set aside as the Oregon National Park. Other lakes are the Upper and Lower Klamath lakes, Lake Harney, and Lake Wallowa, 6,000 feet high, on the Blue mountains.

The Columbia river is 1,200 miles long, one-fourth of it forming the northern boundary of Oregon. It is six miles wide at the mouth, and has a fall of 850 feet near the Cascade mountains, where the government has built a canal, 3,000 feet long. The Willamette, 200 miles long, the Umpqua, and the Rogue, Des Chutes, Umatilla, with the Snake river on the eastern boundary, are other rivers of Oregon. The climate of the western part of Oregon is mild, with an excessive rainfall. The climate is affected by the southwestern trade winds, the ocean currents from Japan, and the protection of the Cascade range, making it much warmer than regions in the same latitude on the Atlantic coast. Eastern Oregon has very little rain, and is colder, though the Rocky mountains protect it from blizzards. Oregon has coal fields, iron ore, in veins from six feet to 15 feet thick, and mines of gold, silver, manganese, and quicksilver. As an agricultural state, its largest crop is wheat, while oats, flax, rye, barley, and buckwheat give large crops. The hop gardens employ large numbers of Chinese, and the prune orchards are among the best in America, while its apples and cherries are noted. Stock raising is an important industry, as cattle and sheep can be kept outdoors all winter. The Oregon pine and the red fir, making the finest of ship timber, with oak, cedar, hemlock, maple, and ash trees, furnish material for its great lumber industry, while its rivers supply the large trade in salmon canning. There are, besides a professional school, nine colleges and universities for men and for both sexes, with 110 instructors and 1,200 students in all departments. The State university, at Eugene, Ore., with a large national land grant; the State Agricultural college at Corvallis; Willamette university, with a college of arts, conservatory of music, and a woman's college, with law and medical colleges at Salem; Albany (Presbyterian) college; McMinnville (Baptist) college; Pacific university at Forest Grove; the Indian training school near Salem, with 180 boys and girls from thirty different tribes; and many normal schools and academies, with a fine system of free schools, furnish the educational equipment of the state.

Oregon was originally the name for all the land between Alaska and California, and was claimed by Spain, Russia, France, Great Britain, and the United States. Spain ceded her rights in 1819, and Russia in 1821, and the Louisiana Purchase settled those of France. In 1811, Astoria was founded by John Jacob Astor, and from 1818 to 1846 the United States and Great Britain by treaty occupied the land together. In 1846, the boundary between the state and British America was fixed, and Oregon territory was formed in 1848, and in 1859 a part of it was made into the state of Oregon. Population 413,536.

O'Reil'ly, John Boyle, an Irish-American poet, was born at Dowth, County Meath, Ireland, June 28, 1844. His father being a teacher by profession, he was given a fine education. He studied journalism from typesetting to the writing of editorials. Although a Fenian, he enlisted in the Tenth Hussars with the intention of exciting a revolt. Being discovered, he was tried for treason, convicted, and banished to Australia in 1866. Escaping from that country he reached the United States in 1869, and became the editor of the *Boston Pilot*. Some of his poems were of high merit and attained deserved popularity. He published a number of volumes of songs and sketches which are now but little known. He died at Hull, Mass., Aug. 10, 1890.

Orellana (*o-rāl-yä'nä*), **Francisco,** a Spanish adventurer, was born at Truxillo, Spain, about 1490. He went with Pizarro to Peru in 1535, sharing in the conquest of that country. In 1540, Pizarro, while exploring the country east of the Andes, sent Orellana with sixty men in a boat down the river Napo after supplies. In three days Orellana reached the Amazon, and, finding it difficult to return, sailed down the river to the sea, being the first European to adventure on its waters. His journey occupied seven months, reaching the ocean in August, 1541. He reported in Spain that he had passed through a country inhabited only by women, who were warriors,

and where gold was used to roof the houses. He obtained a grant of the land along the river, and sailed with four ships and 400 men, but lost his ships and his men, and died of fever after entering the Amazon, about 1550.

Orestes (*o-res'tēz*), a Greek hero, the son of Agamemnon and Clytemnestra. His father was murdered by Clytemnestra and her lover Ægisthus, but Orestes was saved by his sister Electra, and brought up at the court of his uncle in Phocis. His cousin Pylades joined with him in his efforts to avenge his father's death, the pair going secretly to Argos and killing Clytemnestra and Ægisthus. But realizing that he had killed his mother, Orestes became mad and fled from land to land, pursued by the Furies. Learning from Apollo that he could be cured of his madness by bringing the statue of Diana from Tauris in Scythia to Athens, he and Pylades journeyed there, but were seized to be sacrified by the natives. The priestess Iphigenia recognized her brother in Orestes, and with her help they all escaped, carrying the statue with them. Orestes recovered his father's kingdom at Mycenæ, and married Hermione. The story of Orestes is a theme for the tragedies of Euripides, Sophocles, and Æschylus.

Or'gan, one of the largest musical instruments. It is a wind instrument having a large number of pipes, which produce the sounds on admission of air, which is carried to them by means of a bellows. It is played by keys and pedals. The most usual form of the organ is that seen in churches, which consists of four and sometimes five parts, each part being almost a separate instrument. These are called the great organ, the swell organ, the pedal organ, the choir organ, and the fifth part, when it exists, is called the solo organ. Each has its own keyboard, but they are brought close together so that one performer can reach them all. The pedal organ is played with the feet, while the other keyboards are reached by the hands. There is also a system of stops, within reach of the performer's hand, which closes or opens the pipes as the keys do. Organ pipes are made of metal and of wood. The ancient organ was worked by water, and was used in the Roman theatres, Nero being one of its earliest patrons. In the reign of Honorius, 400 A. D., no nobleman's house was complete without an organ, and small ones were carried by slaves from house to house. Constantinople was the great home of organ building in the ancient world, and the first organ built in mediæval Europe was patterned after one brought by Byzantine ambassadors on a mission to Charlemagne. The use of the bellows in organs dates from the time of the Emperor Julian, in the 4th century, though it did not come into general use until the end of the 9th century. The smallest organs ever built were made in the monasteries; they were called regals, and could be held on the palm of the hand. The largest organs in England are those of the Royal Albert hall, Alexandra palace, Crystal palace, St. Paul's cathedral, London, St. George's hall, Liverpool, and the Leeds town hall. Among the largest in the world are the organs at Seville, Haarlem, Rotterdam, and Utrecht. The great organ in the music hall of Boston gave the first impulse to organ building in America. There are large ones now at the cathedrals in Montreal and Boston, the Music hall in Cincinnati, Fremont hall, Boston, Brooklyn tabernacle, and the Auditorium in Chicago.

The AMERICAN ORGAN, called cabinet organ, is a reed organ, the outgrowth of the melodeon, in which reeds are used but not pipes, and the wind is forced in by bellows worked by the feet. The Mason and Hamlin Organ company, founded in 1854, built the first cabinet or parlor organs, making use of an invention of Hamlin's, which consisted in twisting and bending the reeds, so as greatly to improve the tone. These organs have been improved, and are now made in all styles and sizes, some of the larger being nearly equal to pipe organs. There are nearly 100,000 sold yearly in the United States.

Or'igen, one of the most celebrated of the Christian Fathers, was born at Alexandria, 185 A. D. His father was a Christian and a teacher of rhetoric, and he was early trained for public life. Clement of Alexandria was his especial instructor in the principles of Christianity. His father suffered martyrdom when Origen was a young man, and he then sought to support the family by opening a school himself. Bishop Demetrius appointed him master of a famous seminary for catechumens, and having mastered the Hebrew language he soon became an authority upon questions of doctrine and polity. Nevertheless, his opinions were not popular with the ecclesiastics, and he was subjected to many trials, and finally excommunicated in 231. He was received at Cæsarea, where he reopened his school with increased popularity. But the persecutions which followed under Maximinus and Decius drove him to such extremes of suffering that he died at Tyre in 254 A. D. Origen was the first great New Testament exegete that ever lived. He devoted himself to every form of study which promised to throw the least light upon the great problems of theology and philosophy. He practiced the strictest asceticism, and voluntarily subjected himself to the most abject poverty. His work was greatly rewarded in the conversion of multitudes, among whom were many of the leading men of the east. His talents, eloquence, and learning excited the praise of even the heathen writers; and while his doctrinal views have not been wholly accepted by any considerable portion of modern christendom, his purity, unselfishness, and devotion to his Master are beyond praise.

Orinoco (*ō-ri-nō'kō*), one of the great rivers of South America, rises in Venezuela. It divides into two branches near Esmeralda, one flowing south into the Negro river; the other branch, joined by the Guaviare, turns north and passes over the cascades of Maypures and Atures, where the river, 8,000 feet wide, narrows to 20 feet, falling over cascade after cascade, like a series of steps, and shut in by islands and rocks. The Meta and the Apure rivers now join the Orinoco, which flows on, four miles wide, receiving the waters of two more streams before it reaches the delta. About 120 miles from the Atlantic, the delta begins, covering 8,500 square miles and stretching along 165 miles of coast. Of these many channels by which the river empties into the Atlantic, only seven are navigable. The Orinoco is 1,550 miles long; 900 miles are navigable to the falls, and 500 miles above the falls. The river usually floods the country in its course from May to January, the overflow sometimes stretching across for 100 miles. Humboldt and Schomburgh are the great explorers of the Orinoco.

Oriole (*ō'ri-ōl*), any one of a family of Old World birds. The true orioles are related to the crows, and are not to be confused with the so-called orioles of the New World. The latter make a strictly American family, extending from Patagonia into the United States. The two families of birds, although entirely distinct, resemble each other in color, the prevailing shades being yellow and black. It was this circumstance that led to the use of the name for the American birds. The true orioles are common in southern Europe and abundant in Oriental and Australian regions. The golden oriole is yellow and black in color, and makes a hanging nest. It is common in southern Europe, but is rarely found in the British Islands.

Orion (*ō-rī'on*), a hero in Greek mythology, a handsome giant and hunter, in Bœotia. At Chios he fell in love with Eos, or Merope, and cleared the island of wild beasts to please her. When drunk he insulted her, which her father, with the help of Bacchus, avenged by putting out his eyes. He recovered his sight by exposing his eyeballs to the rising sun. There are several stories of his death; one that he was killed by Diana, whose hunter he became, because Eos had carried him off to Ostygia and offended the gods; another that Apollo, angry with Diana's love for Orion, seeing him swimming in the water, pointed out to her a black object, challenging her to hit it, and she shot it with her arrow, finding, when too late, that it was the head of her lover; a third story lays his death to the sting of a scorpion.

Ori'on, the brightest constellation in the northern heavens, is named after the Greek hero Orion, who was placed, with his hound, among the stars, and pictured with a girdle, sword, lion's skin, and club. The three bright stars across the center of the constellation are called Orion's belt.

Orizaba (*ō-rē-sä'bä*), a volcano in Mexico, 15 miles north of the city of Orizaba. It is 18,205 feet in height. The last severe eruption was in 1566.

Ork'ney Islands, a group of islands off the north coast of Scotland. Twenty-eight of the ninety islands forming the group are inhabited, the largest being Pomona. The island of Hoy has fine cliffs and a hill 1,564 feet high, but the other islands are low and treeless, with many small lakes. Farming and fishing and straw-plaiting are the principal industries. On Pomona is a group of large standing stones, arranged in two circles, the inner circle of 100 feet across and the outer one 360 feet across, the largest stones being in the smaller circle. The two towns of the islands are Kirkwall and Stromness. At Kirkwall is the cathedral of St. Magnus, founded in 1138, and a museum with many ancient relics, among others a collection of pins, brooches, bracelets, and silver coins, thought to belong to the earliest period of Scottish history, found on the islands in 1858. The Orkneys, first inhabited by the Picts, were conquered by Norse rovers, and belonged to Scandinavia till 1468, when they were given to James III. of Scotland as a pledge for the payment of the dowry of his wife, Margaret of Denmark. The pledge was never redeemed, and in 1590 on the marriage of James VI. with the Danish princess Anne, Denmark relinquished her claim to the islands. The population, which is partly Scotch and partly Scandinavian, numbers 36,438. See *Orkneys and Shetland*, by Tudor; *Description of the Isles of Orkney*, by Wallace.

Orleans (*ôr'le-anz*), a French city, situated on the Loire river, 75 miles southwest of Paris. The Forest of Orléans, covering nearly 150 square miles, is near it. The ancient walls and gates of the city have, since 1830, been made into boulevards. The Loire is crossed by a bridge 364 feet long. The noted buildings include the cathedral destroyed by the Huguenots in 1567, and rebuilt by Henry IV. and his successors; a museum, and the house of Joan of Arc. There are three statues of Joan, a bronze one having been erected in 1855. The chief industry is market-gardening, and there are some manufactures, but its trade is of most importance, as it is a railroad center, besides having river and canal routes. Orléans was a Celtic town, called Genabum, in 52 B. C., when the Gauls arose there against Julius Cæsar. About 272 A. D., it was named Civitas Aureliani (City of Aurelius), of which Orléans is a corruption. Besieged by Attila in 451; twice plundered by the Northmen; in 1428, it was attacked by the English and delivered by Joan of Arc, called the "Maid of Orleans." During the Huguenot wars it suffered severely, and in the Franco-

German war was held a month by the Germans, and then became the headquarters of the army of the Loire, until its defeat Dec. 3–5, 1870. See *Life of Joan of Arc*, by Michelet. Population 66,619.

Or'leans, Duke of, the title which has been used by three different French dynasties. It was first granted in 1302 by Charles VI. to his brother Louis, who was afterward regent. His grandson became king as Louis XII. in 1498, and the dukedom was merged with the crown. In 1626, Louis XIII. made his brother Jean Baptiste Gaston, duke of Orléans and Chartres, who died childless. The title was granted by Louis XIV. to his brother Philippe, whose son Philippe and grandson Louis Philippe Joseph (Égalité) bore the title. Louis Philippe, son of "Égalité," was duke of Orléans during his exile, until he became king, when his son Ferdinand succeeded to the title. The Comte de Paris, late the head of the Bourbon house of France, has not used the title, which is assumed by his son, the present claimant to the throne of France, Louis Philippe Robert, who resides at Brussels. In French politics, the adherents of the princes of the Orléans family are called Orleanists.

Or'leans, Louis Philippe Joseph, Duke of, best known as "Égalité," was born at Paris, April 13, 1747. He led a dissipated life, and was looked upon coldly by Louis XVI., who disliked his habits, and by Queen Marie Antoinette, who objected to his companions. He became an intimate friend of the then Prince of Wales, in his visits to England, and brought back to France the English vices of horse-racing and hard-drinking. He made himself popular, however, by his profuse charity, opening to the poor the splendid gardens of the Palais Royal. His hostility to the court, and especially to the queen, made him take part against the king, while lavishing his wealth in scattering liberal books and papers throughout the country. He led the forty-seven nobles, who in June, 1789, joined the deputies of the third estate, and helped to change the states-general into a national assembly. He seems to have plotted to become some day a constitutional king, but was not responsible for many of the revolutionary movements, such as the storming of the Bastille, and the march of the women on Versailles, with which he was charged by the Royalists. In September, 1792, when all titles were swept away, he asked for a new name, and took the name of Égalité (equal). He voted for the death of the king. His eldest son, afterward King Louis Philippe, was on the staff of Dumouriez, and went with him into the Austrian camp, and at once, with the other Bourbons left in France, Égalité was imprisoned and by the Jacobins, when they gained power in the convention, he was convicted of conspiracy on slight evidence, dying on the guillotine, at Paris, Nov. 6, 1793.

Or'monde, James Butler, first duke of, lord-lieutenant of Ireland, was born at London, in 1610. He was brought up by the archbishop of Canterbury as a royal ward, his father being dead and his grandfather a state prisoner. In 1640, he was given command of the royal army in the rebellion in Ireland, and managed affairs with ability, though giving satisfaction to none of the numerous parties in Ireland. He sided with Charles in his Irish government, and retired to France when the parliamentary party was successful, but returned and made an effort to restore the royal power. In 1650, he went back to France, and served Charles II. during his exile, accompanied him on his return, and was at two different periods again made lord-lieutenant of Ireland. He was attacked by assassins under Colonel Blood, perhaps instigated by his enemy, the Duke of Buckingham, in 1670, but escaped uninjured. He died in Dorsetshire, England, in 1688.

Ornithol'ogy. See BIRDS.

Orontes (*ō-ron'tēz*), the ancient name of a river in Syria. It rises near Baalbek, and flows north between Lebanon and Anti-Libanus, as far as the city of Antioch, and then flows westward to the Mediterranean. It is 247 miles long, and in the lower part, its rocky banks, 300 feet high, are covered with climbing vines, myrtles, laurels, figs, and sycamores.

Orpheus (*or'fē-us*), a Greek hero, thought to be the son of Apollo and Calliope (*ka-lī'ō-pē*), one of the Muses. His home was in Thracia, where many different places claim to be his birthplace. Orpheus, by his music on the lyre, given him by Apollo, moved men and beasts, trees and rocks. On his travels with the Argonauts, his music rocked monsters to sleep and stopped falling cliffs. When his wife Eurydice died, Orpheus followed her to the lower regions, and his "golden tones" prevailed with Pluto, who allowed him to take her back, provided he did not look around while they ascended; but looking back he lost her forever. According to some traditions, he was killed by a thunderbolt of Zeus for revealing the divine mysteries, and by others he was torn in pieces by the Mænades, and buried at the foot of Mt. Olympus, where a nightingale sings over his grave.

Orsini (*or-sē'nē*), **Felice,** an Italian conspirator, was born in December, 1819, at Meldola, Italy. He studied at Bologna. As the son of a conspirator he was early admitted into secret societies, and was sent to the galleys for life in 1844. Pius IX., by an amnesty, restored him to liberty, but he was soon imprisoned for taking part in political plots. During the revolution of 1848, he took part in the defense of Rome and Venice, and was active at Genoa and in the duchy of Modena, and after its suppression lived for some years

in England, where he was intimate with Mazzini. In 1854, while stirring up insurrection in Milan, Trieste, and Vienna, he was arrested and sent to the fortress of Mantua, whence he escaped in 1856 and fled to England. There he supported himself by lecturing and wrote *Austrian Dungeons in Italy*. He at last planned the assassination of Napoleon III., the great obstacle, as he thought, in the way of Italian independence. With three associates he stood near the opera house in Paris, on the evening of Jan. 14, 1858, and when the emperor's carriage drove up, threw three bombs under it, which exploded, killing ten persons and wounding 146, but not injuring the emperor or empress. He and one companion (Pieri) were guillotined, March 13, 1858, the others being sentenced to penal servitude. See *Memoirs and Adventures*, by himself.

Or'tolan, a class of birds belonging to the finch family. It is about six inches long, with head, neck, and breast of a yellowish gray, with brown wings. It builds its nest of dry grass on the ground in open fields, though sometimes under low bushes. They are found in summer as far north as the Arctic circle, and in winter south as far as Abyssinia and India. They are caught in large numbers in nets when on their journeys, and fattened in dark rooms, as their flesh is considered a great delicacy. In Japan, they are pickled with spice and vinegar. The Romans gave large sums for them, and they are still highly prized in Italy.

Or'ton, James, an American naturalist, was born at Seneca Falls, N. Y., April 21, 1830, and died in Peru, Sept. 25, 1877. In 1867, he went with an expedition through South America and found the first fossils discovered in the valley of the Amazon, and made a journey from Para to Lima, in 1873, and after another tour through Peru, died in crossing Lake Titicaca. His published works include, *The Andes and the Amazon*, *Underground Treasures*, and *Comparative Zoology*.

O'sage Orange, a tree, native of North America, somewhat like the mulberry. It was found growing in the country of the Osage Indians, which, with its yellow globes of fruit, gave it its name. It is also called mock orange. It grows from 20 to 60 feet high, and is a very valuable tree for its wood, which is yellow, fine grained, takes a high polish, and is very durable. It is used for posts, paving blocks, etc. The leaves are used for feeding silkworms in place of the mulberry, with a difference of opinion as to the result. The fruit, large and round, with a rough skin, has a woody pulp and bitter juice, and is not eaten. The tree has been largely used in America as a hedge plant, for which its rapid growth, thorny branches, and freedom from disease adapt it.

O'sages, a tribe of American Indians of the Dakotah family. They were found by Marquette on the Missouri in 1673, but were driven by their enemies to the Arkansas. They fought with the French against the English, and against the Chickasaws. They ceded their lands at different times to the government, and in the Civil war about 1,000 of the tribe went south. In 1870, the tribe was removed to the Indian territory and placed in charge of the Quakers, where they have grown more civilized, having a school and cultivating about 2,000 acres of land.

Osaka (*ō-sä'kä*) or **Ozaka,** the second largest city in Japan, situated at the head of the gulf of Osaka. It covers about ten square miles, and is crossed by canals with more than 1,000 bridges. The fine castle, built of enormous stones, in 1583, and the palace, which was destroyed in 1858, were perhaps the handsomest buildings in Japan. The city is the headquarters of the rice and tea trade, and the commercial center of the empire. The harbor does not admit of very large vessels. There is a foreign settlement, occupied mostly by missionaries. Population 821,235.

Os'car II., Frederic, king of Sweden and Norway, was born at Stockholm, Jan. 21, 1829. He is the great-grandson of Napoleon I.'s famous general, Marshal Bernadotte, the first king of the new independent kingdom of Norway; he succeeded his brother, Charles XV., in 1872. He has followed the policy of his brother, carrying out reforms and reorganizing the army and the railroads. He has published a volume of poems, a translation of Goethe's *Faust*, and a sketch of Charles XII.

Osceola (*os-ē-ō'lä*), a chief of the Seminole Indians, was born in Georgia, in 1804. His father was an English trader, and his mother the daughter of an Indian chief, who took him to Florida when a child, where he became influential among the Indians. His wife, the daughter of a runaway slave, was taken from him, and for his threats of revenge he was seized and imprisoned for six days by General Thompson, whom he killed, with four others, six months afterward. This was the beginning of the second Seminole war. At the head of a band of 200 or 300 Indians and runaway slaves, he carried on the contest for nearly two years, in the almost impenetrable Everglades. On Oct. 21, 1837, while holding a conference under a flag of truce, he was treacherously seized and imprisoned at Fort Moultrie, S. C., where he died Jan. 30, 1838. He is the hero of Mayne Reid's story, *Osceola*.

Osh'kosh, Wis., the county seat of Winnebago county, is situated at the confluence of the upper Fox river and Lake Winnebago in a thickly-settled and fertile region. Being naturally the center of the lumber interests of the Fox and Wolf rivers, it early became commercially important, and has now a population of 28,284. Besides its numerous sawmills, it is noted for its extensive manufacture of sash, doors, and blinds, matches, carriages,

sleighs and farm wagons, trunks, furniture, logging tools, grass-twine goods, and canned goods.

It has fine public schools and churches, several large parochial schools, a state normal school, a state fish hatchery, and three miles north is the Northern State hospital. The city has two hospitals, two parks, a beautiful library building of classic design, five banks, two daily papers, three railroads, a line of steamers for lake and river commerce, and an electric railway system connecting the city with Neenah, Menasha, and Appleton. Near by is Lake Winnebago, a sheet of water thirty miles long and twelve miles broad; it is famous for its fishing and its beautiful summer resorts, and tourists come from afar to enjoy its waters.

O'sier. See WILLOW.

Osiris (*ō-sī'ris*), the greatest of Egyptian gods, is the son of Set (the earth) and Nut (heaven). He was slain by Set, his father, and avenged by his son, Horus. He judges the dead in the lower world. He is represented usually in human form, and always with the head of a man. His symbols are the evergreen and the tamarisk, and a kind of ibis, with long plumes.

Osman Digna (*ŏs-măn' dĭg'na*), a leader of the Sudanese Arabs, was born at Suakim about 1836. His father and grandfather were both slave-dealers; and the son followed the same calling, having marts for his slaves at Khartum and Berber on the upper Nile. The rebellion of the Mahdi broke out on the White Nile in December, 1881, Osman having himself prepared the way for a revolt against the authority of the khedive. On Aug. 3, 1883, Osman was defeated before Suakim by Tewfik Bey. He lost a second battle, September, 1885; and won a third, Dec. 21, 1888. In this engagement he met Gen. Sir F. Grenfell. On Feb. 21. 1891, he returned in force to be routed anew; and again, in 1894, he appeared at the head of a new army to be driven off by the Egyptian cavalry. At daybreak, April 8, 1898, General Kitchener, in command of the English and Egyptian contingents, sent to restore order in the Sudan, encountered two divisions of Dervishes under command of Emir Mahmoud and Osman Digna on the Al-bara. Mahmoud was captured, but Osman again escaped. Out of the 20,000 Dervishes under them, 2,000 were slain. Once more the Sudanese were rallied; and on Sept. 6, the battle of Omdurman was fought, and 11,000 Sudanese were slain, while the wounded were reported as 16,000. The khalifa, who had succeeded Mahmoud, and Osman Digna fled, leaving their dead and wounded to the care of the English conquerors.

Osman', Nubar Pasha, a Turkish general (pasha signifying governor), was born at Tokat, in Asia Minor, in 1832. He was educated at the military schools of Constantinople and became a cavalry officer. He fought in the Crimean war; took part in suppressing the rebellions in Syria (1860); in Crete (1867), and in the Yemen (1874). He was commander of the Fifth army corps in the Turkish army at the outbreak of the Russo-Turkish war in 1876; was commandant at Widdin; and, after being driven back from Scalevitze, he intrenched and maintained his army at Plevna almost four months, despite the fierce bombardment of the Russian forces. He was, however, forced to surrender, Dec. 10, 1878, at which time he still commanded 43,000 men. His sword was returned to him by the czar, and he was promoted by the sultan to be minister of war in 1878. He was also made governor of Crete. In 1894, he became grand marshal of the palace. He died at Constantinople, April 4, 1900.

Os'prey. See FISHHAWK.

Ossian (*osh'ian*), the great Gaelic poet, was, according to tradition, the son of Fionn MacCumhail, who lived in the 3d century A. D. Fionn gathered a band of warriors about him whose adventures constitute the literature of the Feinn. Ossian is said to have been carried away to the "isle of the ever-young," and when he returned, old and blind, to have told these stories of the Feinn. Ossian is best known through the work of James MacPherson, who in 1760, 1762, and 1763, published *Fingal*, a poem in six books; *Temora*, another poem, in eight, and some shorter pieces, all claiming to be translations of Ossian, the son of Fionn or Fingal. They brought him fame and wealth, and were translated into nearly every European language, Goethe, Schiller, and Napoleon being among his admirers. But Dr. Johnson, with others, attacked them as forgeries, claiming that there was no Gaelic literature as ancient as the original of Fingal claimed to be. The truth seems to be that these translations were largely the work of MacPherson, and the Gaelic texts were prepared with or without the aid of his friends; but the heroic literature of the Gael on which his work was founded remains. See *Ossian*, by Clerk; *Reliques of Gaelic Poetry*, by Brooke.

Ostend (*ŏs-tĕnd'*), a watering place in West Flanders, on the German ocean, 77 miles northwest of Brussels. Its sea wall, 3 miles long, 40 feet high, and 105 feet broad, forms a fine promenade, and two wooden piers projecting on each side of the harbor are used for the same purpose. It is the resort from July to September of from 20,000 to 25,000 visitors from Germany, Russia, and all parts of the continent. It is an important fishing station, has a school of navigation, a lighthouse, and manufactories of linen, sailcloth, candles, and tobacco. It dates from 1072; was besieged by the Spaniards from July 7, 1601, to Sept. 20, 1604; surrendered to the

allies in 1706, and to the French in 1745. Since 1865, it has been without fortifications. Population 38,481.

Osteopathy (*ŏs-tē-ŏ'pă-thĕ*), a system of treating diseases by manipulation, which was invented by Dr. A. T. Sill, then of Baldwin, Kan., but later of Kirksville, Mo., where a large school has been founded. The system takes its name from the theory that all diseases are "caused by some displacement of some bone which causes obstruction to the flow of one of the fluids." This trouble it is sought to remove by manipulation of the parts affected, permitting the "free operation of the fluids of the body," in which, it is asserted, all medicinal virtues by nature inhere. Special legislation in several western states permit the graduates of osteopathic schools to practice as licensed physicians.

Os'trich, the largest living bird, a native of the plains and deserts of Africa. The wings are small and not adapted for flight, but the bird is a swift runner. It is said to go at the rate of a mile a minute with a stride, when under full speed, of twenty-two to twenty-eight feet. The male ostrich reaches a height of seven feet and weighs from one hundred and fifty to two hundred pounds. It is called the "camel-bird." The male has black feathers on the body, and white ones on the wings and tail. The latter are the plumes of greatest value. The female is plainer. The head and neck are unfeathered in both. There are three species of ostriches in Africa, they live in small flocks and are timid and difficult to approach. They are hunted on horseback, and advantage is taken of the fact that they run in a circle. About ten eggs are laid in a hole in the sand, and sat upon by the male at night, and by the female by day. These eggs are from five and one-half to six inches in longest diameter, and are equivalent to about twenty-four eggs of the common fowl. The shell is so thick and strong that it has been used as a water vessel by South African tribes. In their native haunts, ostriches feed on grass, herbs, insects, and reptiles, but, in captivity, they swallow nearly everything not too large. Ostrich plumes have been used for ornament and adornment from ancient times. The ladies of ancient Rome were fond of these beautiful feathers. The plumage of the adult bird is assumed about the third year. One bird will yield feathers of a value from 40 to 150 dollars at a plucking. The quality of the feathers depends upon the pasturage. Ostrich farming is now carried on in Cape Colony, Australia, Buenos Ayres, California, and other places where the African ostrich has been introduced. See Douglass' *Ostrich Farming in South Africa;* Martin's *Home Life on an Ostrich Farm.*

AFRICAN OSTRICH.

Oswe'go, a city of New York, is situate on Lake Ontario, at the mouth of the Oswego river, 35 miles from Syracuse. It is divided by the river, which is crossed by three bridges, and has five miles of water frontage on the river, and two and a half miles on the lake. It is the chief port on the lake, with a breakwater and lighthouse, and has five miles of wharves and a dozen elevators. Fort Ontario guards the harbor. The city is built on slopes rising to 100 feet, and the shore of the lake is a bluff from 40 to 50 feet in height. The public buildings include the court house, city hall, state armory, and a public library. The river has within the city a fall of 34 feet, which is used as water-power for flour mills, knitting mills, foundries, and iron works, making steam shovels, dredges, and steam engines; there are also woolen factories, car works, and breweries. The factory for corn starch is one of the largest in the country, covering more than four acres. The state normal school is located here. Oswego was a trading post of the English in 1720, and in 1727 a fort was built there. It was taken by the French in 1756, and by the British in 1812. It became a city in 1848. Population 22,199.

Othman (*ŏth-măn'*) or **Osman I.,** surnamed "The Conqueror," was born in Bithynia, in 1259. When the Mongols overthrew the sultanate of Iconium, in 1299, he seized a portion of Bithynia. Then forcing the passes of Olympus, he took possession of the territory of Nicæa, and gradually subdued a large part of Asia Minor, and thus became the founder of the present empire of Turkey, called from him the Ottoman empire. He died in 1326. See TURKEY.

Ot'ho I. or **Ot'to the Great** was born in 912. He was the son of Henry I., emperor of Germany, and succeeded his father in 936. His reign was very successful; many tribes were brought by him into subjection; he held almost supreme power in Italy, both over the kings of Lombardy and the popes of Rome; he consolidated the German empire, and established Christianity in both Scandinavian and Slavonic lands; dying in Prussian Saxony, in 973.

O'tis, Elwell Stephen, an American soldier, was born at Frederick, Md., March 25, 1838, and graduated at Rochester university, N. Y., in 1858. He studied law at Harvard and graduated there in 1861. On Sept. 13, 1862, he entered the volunteer army as a captain (140th N. Y.), and was mustered out June, 1865, as brevet brigadier-general "for distinguished

services." He was appointed lieutenant-colonel in the regular army, July 28, 1866, and rose to be brigadier, Nov. 28, 1893. He was appointed major-general of volunteers and assigned to the Philippine islands, May 4, 1898, where he took chief command on the departure of General Merritt for Paris. He became military governor of the islands in 1899, and was appointed one of the Philippine commission in the same year. He was promoted major-general in the regular army, January, 1900. General Otis was a famous Indian fighter during the years 1867–81, and published a book, *The Indian Question*, in 1878.

ELWELL STEPHEN OTIS.

O'tis, Harrison Gray, an American statesman, was born at Boston, Mass., Oct. 8, 1765. He studied at Harvard college, and was admitted to the bar in 1786. Sent to the state legislature, in 1796, he soon became leader of the Federal party. He was one of three commissioners sent in 1814 by Massachusetts to Washington, to present to the government the subject of the damages inflicted on the New England states by the war with Great Britain. As United States senator in 1820, in the debate on the Missouri question, he strongly favored the restriction of slavery. He was a popular orator, and opposed the antislavery movement in his later years. He died at Boston, Oct. 28, 1848.

O'tis, James, an American statesman and orator, was born at West Barnstable, Mass., Feb. 5, 1725. He studied at Harvard and at Boston, was admitted to the bar at Plymouth in 1748, and moved to Boston in 1750. In 1760, when advocate-general, the revenue officers asked his aid in obtaining from the superior courts search warrants by which they could enter any man's house in search of smuggled goods. Otis considered this illegal and refused, resigning his position and appearing on behalf of the people. His speech on the subject lasted five hours, and made a great impression, John Adams saying of it afterward: "The child Independence was then and there born." He was elected to the assembly, and was a delegate to the Stamp Act congress, which met in New York the same year; and a member of a committee of that body to prepare an address to the English house of commons. While in the Massachusetts legislature, the governor of the state requested that a letter on relief from taxation, sent to the other colonies, should be taken back by the legislature. Otis opposed the governor's requisition in a speech called by his opponents "the most treasonable declaration ever uttered," and carried the house with him by a vote of 92 to 17. He was severely beaten by some revenue officers in Boston in 1769, and lost his reason as a consequence of a sword cut on his head. He published several political pamphlets, *The Rights of the Colonies Asserted* being the best known. He was killed by lightning May 23, 1783, while standing at the door of his home at Andover, Mass. See *Life*, by Tudor.

Ot'tawa, the capital of the Dominion of Canada, is situated on the Ottawa river, 120 miles from Montreal. The government buildings are on a bluff, called Barrack hill, 150 feet above the river; they form three sides of a square, and include a fine library building, with 160,000 volumes, and the Victoria tower, 180 feet in height. The governor-general's house (Rideau Hall) is about a mile from the city. The Episcopal bishop of Ontario and Roman Catholic bishop of Ottawa have their residences in the city. There is a Catholic cathedral and college, a normal school, ladies' college, musical academy and art school, and a fine museum. The Chaudière falls, 40 feet in height, on the Ottawa river, and a smaller fall on the Rideau river, give a fine water-power, and supply the many lumber mills, flour mills, and factories of the city; while the Rideau canal across the city, the Gatineau and the Du Lièvre rivers increase the facilities of the lumber trade, which is the great industry of the region. Flour, matches, ironware, brick, and leather are also manufactured. Ottawa was founded in the last part of the 18th century by a Bostonian named Wright. He called the village Hull, a place now having 12,000 inhabitants. He sold the lots on which Ottawa now stands to a man to whom he was in debt for labor. In 1823, Colonel By was sent by the British government to survey the Rideau canal, and the settlement was for a time called Bytown. The name was changed to Ottawa in 1854, and in 1858 it became the capital of the Canadian Dominion. Population 59,902.

Ot'tawa, one of the largest rivers of British America, rises about 300 miles north of Ottawa city, flows west 300 miles to Lake Temiscamingue, and then 400 miles southeast into the St. Lawrence, where its two mouths form the island of Montreal. It sometimes widens into lakes, and then narrows to 120 or 150 feet, but with its branches carries on its waters perhaps the largest lumber trade in the world. The navigation of the river is improved by a system of canals and slides, made necessary by its many falls.

Ot'tawa, Ill., the capital of La Salle county, at the junction of the Illinois and Fox rivers, in northern-central Illinois, 82 miles southwest of Chicago. It is situated in a rich region, and has a considerable trade in the shipping of grain, lumber, and produce; besides growing manufacturing industries, which include window glass, glass bottles, lamp chimneys, pottery, tile roofing, drain tile, sewer pipe, firebrick, carriages, wagons,

organs, saddlery, and harness, agricultural implements, etc. Population 10,588.

Ot'tawas, a tribe of American Indians of the Algonquin family, living, when first found by the French explorers, in the northern part of Michigan. They fled from the Iroquois beyond the Mississippi, to the country of the Sioux, and after war with them went back to Mackinaw. They joined with the French, and after the settlement of Detroit a part of the tribe lived near by. At the close of the last war of the French for Canada, their chief, Pontiac, headed a great conspiracy against the English. In the Revolutionary war, they helped the English, but finally joined in the Indian treaty of Greenville, Aug. 3, 1795. A band of them settled on the Miami river, and when their land was ceded to the United States, a tract 34 miles square was reserved to them on the Miami. Other bands have taken up lands in the Indian territory, while some are still found on the shores of Lake Superior and in Canada.

Ot'ter, an aquatic carnivorous animal related to the weasel, and highly valued on account of its fur. Otters inhabit both the Old and the New Worlds. They have an elongated low body, with short limbs and webbed feet. The American form is about four feet long; it ranges over nearly all the temperate zone of North America and is fond of sliding down slopes into the water. In winter, it also slides on the snow. They feed almost exclusively on fish. The common otter of Great Britain and Europe is similar in form, but shorter, being about two feet long without the tail, which is about seventeen inches long. The fur is soft, of a brownish color, lighter on the throat and below. They are expert swimmers and divers and easily overtake fish which they bring to shore to devour. In some parts of India and China the otter is taught to catch fish, and also to assist in driving them into nets. The sea otter which is a related form, belonging, however, to another genus, lives about the Aleutian Islands in the North Pacific. It does not feed on fish but on clams, sea urchins, and crabs. Its fur is very valuable.

OTTER.

Ot'terburn, Battle of, "the hardest and most obstinate battle ever fought," according to Froissart, took place near Otterburn, a small village in Northumberland, England, about sixteen miles south of the Scottish border, and thirty-two miles from Newcastle. Douglas, with his Scottish army, carried away Hotspur's pennon from Newcastle, saying that he would plant it on his own castle. "You shall not carry it out of Northumberland," swore Hotspur (Harry Percy). So the Scots encamped on a slope near Otterburn to give him time to regain his pennon. Hotspur, with 8,600 men, nearly four times the Scotch force, attacked their camp. Douglas, hewing the way before him with his mace, fell mortally wounded, anxious only to hide his death from his followers till they had won the victory, saying: "Long since I heard a prophecy that a dead man should win a field, and I hope in God it shall be I." The Scots gained the day, taking Harry Hotspur and his brother, Robert, prisoners. The date of the battle is Aug. 19, 1388. The Scotch ballad of *Otterburn* and the English ballad of *Chevy Chase* tell the story of this battle. See *History of the Battle of Otterburn*, by White; and Percy's *Reliques*.

Ot'toman Empire. See TURKEY.

Ottum'wa, a city in Wapello county, Ia., is on Des Moines river, 85 miles southeast of Des Moines. Surrounded by a fertile country, with fine water-power, it has a large trade, and manufactures carriages, woolen goods, sewing-machine attachments, and agricultural implements, with flour, starch, and linseed-oil mills. It is in the heart of the Iowa coal fields. Population 18,197.

Oudenarde (*ou'den-dr'de*), a town in Belgium on the Scheldt, 33 miles west of Brussels. It is noted as the scene of the famous battle of Oudenarde, brought on by the efforts of the French to retake the city from Marlborough, who had captured it in 1706. It was the third of Marlborough's four great victories, and was gained July 11, 1708.

Oudinot (*ō'dē-nō'*), **Nicolas Charles,** duke of Reggio, and marshal of France, was born at Bar-le-Duc, France, April 25, 1767. Entering the army at seventeen, he won distinction, gaining the cross of the Legion of Honor in 1805. He was made commander of ten battalions, which became famous as "Oudinot's grenadiers." He was at Austerlitz and Jena, and won the battle of Ostrolenka, Feb. 18, 1807. For his brilliant services in the Austrian campaign of 1809, he was made marshal of France and duke of Reggio. He was given charge of the occupation of Holland in 1810, and served in the Russian campaign and in the battles of 1813 between the French and Austrians. He was one of the last to leave Napoleon, but left him entirely, remaining on his estates during the "Hundred Days." He was made minister of state, commander of the royal guard, and a peer of France after the second restoration, and in 1823 commanded the first division of the army of Spain, and was for a while governor of Madrid. He died at Paris, Sept. 13, 1847. See *Napoleon and His Marshals*, by Headly.

Outram (*ōtram*), Sir **James,** a famous English general, the "Bayard of India," was born in Derbyshire, England, Jan. 29, 1803. He was educated at Aberdeen, and entered the Indian service as a lieutenant in the Bombay infantry. In 1839, as aid-de-camp to Sir John Keane, he took his famous ride of 335 days across Afghanistan, disguised as an Afghan merchant. He defended the British residency at Hyderabad against 8,000 Beluchis in February, 1843, and in 1854 was given the highest office in India, the residency of Lucknow. After a brilliant campaign as commander of the Persian expedition, he landed in India to find the mutiny raging, and was offered the command of the forces marching to the relief of Lucknow. He yielded the position to his old lieutenant, Havelock, who had already fought eight successful battles with the rebels, and accompanied the army as commissioner from Oudh, and serving in the army as a volunteer. After the relief of the city, he took command, and was in turn besieged, holding out against great odds until relieved by Sir Colin Campbell (afterward Lord Clyde). In recognition of his services he was made lieutenant-general, and created a baronet. He spent the winter of 1861–62 in Egypt, and died at Paris, March 11, 1863. He was buried in Westminster Abbey, and statues of him are erected at London and at Calcutta. See *Life* by Goldsmid.

Ou'zel, a popular name given to several birds, mostly of the thrush (*Merulidæ*) family. In Shakespeare and in Tennyson the blackbird is called an ouzel, but in America it is for the most part restricted to small birds which look like land birds but which are aquatic in their habits. The American "water ouzel" resembles a catbird in appearance, is solitary in its habits, and lives along the banks of dashing streams. It will surprise the spectator by dropping suddenly into a brawling mountain cataract, and then appear swimming along through the pools by the use of its wings, or, it may be, running swiftly along the bottom of the stream by means of its feet. Its food is composed of small mollusks or aquatic insects and their larvæ, which it seeks among the stones at the bottom of the brook.

O'vary (in plants), the name of that bulbous part of carpels or pistils which contains the ovules. As the term ovary is already well established among animals in connection with the organ which produces eggs, its present application in flowers is extremely unfortunate, since the ovary of flowers holds no relation to a female sex organ. It has been suggested on this account that the term "ovulary" be substituted for it in flowers. See FLOWER.

O'verbeck, Friedrich Johann, a noted German painter, was born at Lübeck, Prussia, in 1789, and studied at Vienna and at Rome. He, with four others, founded a school of art that had much influence in Europe, though they were mocked at with such names as "Pre-Raphaelites" and "Nazarites." A Madonna, painted in 1811, brought Overbeck into notice, and he was employed by the Prussian consul to execute frescoes in his house at Rome illustrating the story of Joseph. His chief work is a fresco at Assisi, *The Vision of St. Francis.* Among his famous pictures are *Christ's Entry into Jerusalem,* at Lübeck; *Christ's Agony in the Garden,* at Hamburg; *The Incredulity of St. Thomas,* at London. His drawings, as well as his paintings and frescoes, have many of them been engraved. He died at Rome, Nov. 12, 1869. See *Life,* by Atkinson, in the "Great Artists" series.

O'vertones', sometimes called "harmonics," are a series of weak tones which accompany the production of any given note on a musical instrument. The lowest string on a guitar is called an "E string," because, when plucked, the lowest and the loudest note which it can emit is E. This note, E, is, therefore, called the "fundamental." If we denote the number of vibrations per second in this fundamental note by unity, then the series of fainter notes, which accompany the fundamental whenever the string is plucked, will have frequencies which are denoted by the numbers 2, 3, 4, 5, 6, 7, etc. These secondary notes are called "overtones" or "harmonics." They are very marked in the case of stringed instruments provided with sounding boards (such as the piano and violin), and add greatly to the richness of the tone. They are nearly absent in the case of the tuning fork, and hence the pure, but thin tone of the fork.

Ov'id (Publius Ovidius Naso), the Latin poet, was born in Italy, March 20, 43 B. C. He was educated at Rome, his father putting him under the best of teachers to train him for the bar. He soon gave up the practice of law and went to Athens, Asia Minor, and Sicily. His first success was won by his tragedy, *Medea.* Then followed his *Epistles,* imaginary love-letters. His *Art of Love,* his masterpiece, was published in three books. The *Metamorphoses,* in fifteen books, contains some of the finest work in ancient literature. The *Fasti,* only six books of which were finished, is a poetical commentary on the calendar, giving the origin of Roman feast days, etc. He was banished by the Emperor Augustus to Tomi, on the Euxine, south of the mouth of the Danube, for some unknown offense. He admitted that the punishment was deserved, but says he was rather the witness than the author of the crime. In 9 A. D., he left Rome, making his home for the last eight years of his life at Tomi, constantly writing appeals to the emperor for a release from the sentence of banishment. Here he wrote the *Tristia,* in five books, and *Letters,* in four, making him one of the most prolific of Latin poets. He died in 17 A. D.

O'vulary. See OVARY.

O'vule (in plants), the peculiar megasporangium of seed-plants, which in gymnosperms is exposed upon a scale, and in angiosperms is inclosed within that part of the carpel called the ovary. It is the ovule which, after fertilization, becomes the seed. The ordinary ovule consists of the following parts: one or two "integuments," which are distinguishable only above, and which leave a narrow passage-way (micropyle) through which the pollen tube passes; the "nucellus" or main body of the ovule, inclosed by the integuments, and containing the single large megaspore ("embryosac"). Ovules are of various sizes, and occur in various numbers in ovaries, from solitary to almost innumerable. Various modifications of ovules have received technical names, which are of no special value to the general student.

Vertical section of a flower-bud, showing sepals (*s*), stamens (*a*), and an ovule (*kk*) with two integuments.

Ow'en, Sir **Richard,** a British naturalist, was born at Lancaster, England, July 20, 1804. He studied medicine at Edinburgh and London, but soon began his work in zoology and comparative anatomy, by preparing catalogues of the collections in the museum of the Royal College of Surgeons, and lecturing on comparative anatomy. In 1856, he became superintendent of the natural history department of the British museum, a position favorable for his studies on living and fossil animals. He visited Paris and made the acquaintance of Cuvier, with whose name his will always be connected in the science of zoology. Owen's researches in zoology number nearly 400; they are largely devoted to structure, and embrace every class of animals from a sponge to man. He produced monographs, or important papers, on the pearly nautilus, the Venus flower-basket, king crab, the mudfish, anthropoid apes, and many extinct birds and reptiles. Among his voluminous writings are, *Comparative Anatomy of Invertebrates* (1855), *Comparative Anatomy and Physiology of Vertebrates* (1855), *The Skeleton and the Teeth, History of British Fossils, Reptiles, Birds, Mammals.* He died Dec. 18, 1892. See Owen's *Life of Richard Owen* (1894).

Ow'ensboro, Ky., a city on the Ohio river, the capital of Daviess county, in northwestern Kentucky, 150 miles southwest of Louisville. The city stands high, and in a fertile region, both in regard to agriculture and its mineral products. Its chief industry, however, is tobacco, of which there are some 25 factories and stemmeries; there are also a number of whiskey distilleries; foundries and machine-shops; lumber, flour, planing, and steam-shingle mills; sewer-pipe and brick works. There are good schools, churches, and public buildings. It is served by the Louisville and Nashville, and the Louisville, St. Louis, and Texas railroads. Population 13,189.

Owl, a bird of prey with a flat face and rosette of feathers about the eyes, making them appear large and conspicuous. There are about two hundred species of owls throughout the world. For the most part, they are birds of night and pass the day in secluded and dark places. A few, like the snowy owl and the hawk owl, are day birds. The common owls feed, for the most part, on smaller birds and field mice. Since the latter are very destructive to crops and vegetation the owls should be protected, if for no other reason than for their war upon these rodents. The screech owl, or mottled owl, is one of the commonest in the United States. It nests about houses. It is quiet during the nesting season, but after the young are reared, in July and August, its voice may be heard at night. It is not a screech, but a tremulous, quavering sound of mournful quality. The barred owls are next in abundance. They live in deep woods and their cry of *whoo—whoo—who!* gives them the name of hoot owls. They destroy many mice. The eared owls, or horned owls, have tufts of feathers on their head like small horns. The great horned owl is common and one of the strongest and best known of our owls. The snowy owl, a beautiful bird either pure white or barred with black, nests in the north and visits the United States in winter. It is a day owl. It feeds on fish, birds, and sometimes carrion. The burrowing owl is a small western owl living in the holes of prairie dogs. The barn owls belong to a distinct but closely related family. They have long faces, the feather discs on which are nearly triangular, and they are often called monkey-faced owls.

LONG-EARED OWL.

Ox'ford, a city of England, and the seat of the University of Oxford, is situate near the union of the rivers Cherwell and Thames, 52 miles from London. The two rivers form a rectangle, on which the old part of the city stands. In the center of the town, called "Carfax,"

meaning four-forked, the four main streets cross each other, running north and south, and east and west. Besides the university buildings, there is St. Michael's church, with its tower, built in 1070; the Clarendon building, used for the Clarendon press until 1830; the Indian institute, with a library and museum for the use of members of the India service or natives of India; Godstow, a ruined nunnery; St. Barnabas, St. Aloysius, and St. Aldgate's churches, and the Church of All Saints; Somerville Hall, and Lady Margaret Hall, colleges for women; Wycliffe Hall, a theological school; the town hall and public library. A cross, known as the Martyr's Memorial, was erected in 1841, in honor of the Oxford martyrs, Ridley, Latimer, and Cranmer. The Port Meadow is an open common, and the university parks are kept in order by the university. Oxford is mentioned in the Saxon Chronicle as far back as 912 A. D. The tower, now St. Michael's church, was built by the Norman conquerors and commanded the approach to the north gate of the city, which was removed in 1771; Empress Maud (Matilda) took refuge in Oxford when driven from London by Stephen of Blois (1142); and in 1258, the reform known as the "Provisions of Oxford," was the work of the "mad parliament" sitting at Oxford; and in the civil war it was for a few years the seat of the parliament and court of Charles I. Population 53,000. See *Oxford City*, by Boase, in "Historic Towns" series; *Oxford*, by Lang.

Ox'ford, Univer'sity of, one of the two great seats of learning in England, situated at Oxford, is a collection of colleges under one corporation known as "the chancellor, masters, and scholars of the university of Oxford." There are twenty-one colleges and two halls, to some one of which all members of the university belong. The teaching staff numbers 94 professors, with 3,500 students. Each college is a distinct institution with its own rules. The head of the university is the chancellor, who is usually chosen from the nobility, and holds office for life, and receives no salary. The vice-chancellor, appointed by the chancellor, serves four years, and is the real head of the university. There are four governing bodies, called house of convocation, ancient house of congregation, and modern house of congregation, and the council. These different bodies are made up of college officers, professors, masters of art, and resident graduates. The real management is in the hands of the council, consisting of the vice-chancellor, two proctors, who are the police officers of the university, six heads of houses, six professors, and six graduates. The teaching in the colleges of the university is carried on by professors, lecturers, and tutors. The professors do very little teaching, giving lectures perhaps twice a week, and devoting their time largely to independent study. The college lecturers are the real teachers, but belong to the separate colleges, though their lectures are now open to the whole university. A large part of the work of the college course consists in taking papers, essays, and translations to the tutors, who may be employed by individuals or by small classes.

Oxford, beginning in the early part of the 12th century, grew rapidly, its scholars were numbered by thousands as early as the 13th century. The four great orders of mendicant friars were attracted to Oxford, and established their schools in their convents, and were followed by other orders of monks. The Reformation, with the breaking up of the monasteries, destroyed half the glory of Oxford. The earliest college is Merton college, founded in 1264, and transferred to Oxford in 1274, and was the first institution organized into a college at Oxford, the earlier teachings having been carried on in halls. The old quadrangle and the library of Merton college are among the most ancient college buildings in Oxford. Baliol college, founded by the mother of John Baliol, king of Scotland, in 1268; Oriel college, founded in 1326 by King Edward II.; Queen's college, in 1340; All Souls' college in 1347; and Jesus college, founded in 1571 by Queen Elizabeth, are among the older colleges. Christ Church is the cathedral of the diocese of Oxford and also a college. The cathedral was instituted by Henry VIII., in 1546, and the college founded by Wolsey in 1525. The entrance tower contains "Great Tom," one of the largest bells in England. The buildings of Magdalen (*mâd'lin*) college, founded in 1457, are thought to be the finest college buildings in the world, and the musical services in its chapel have been famous for centuries. Other buildings connected with the university are the Bodleian library, founded in 1602 by Thomas Bodley, and now one of the largest libraries in the world; Radcliffe library, and the Ashmolean museum, the earliest public museum in England, containing British antiquities and some from Cyprus, Egypt, etc.; the Sheldonian theatre, built in 1669, for holding the ceremonies of the university; St. Mary's church, where are preached the university sermons, and the university observatory. The parks are the scene of most of the football games, and for a quarter of a mile along the river are moored the barges of the boat clubs. See *Tom Brown at Oxford*, by Hughes; *Colleges of Oxford*, by Clark.

Ox'ford, a town in Ohio, 40 miles northwest of Cincinnati. It overlooks the beautiful Miami valley and has some manufactories of agricultural implements, but is best known as a college town. It is the seat of Miami university, founded in 1809, and noted for the high positions attained by its graduates. The Western Female seminary, a school modeled after Mt. Holyoke seminary, and the Oxford institute, also a college for women, are situated here. Population 2,009.

Ox'ford, a town in Mississippi, 30 miles south of Holly Springs, is the seat of the University of Mississippi, founded in 1844, with five buildings and 640 acres of land. The Oxford academy, Oxford institute, and Union Female college are all situated here. Population 1,825.

Ox'us, the ancient name of a river in central Asia, now known as "Jihun," or "Gihon," and "Amu Daria." It rises in the tablelands of Central Asia, flows through Bokhara and Khiva, and empties into the sea of Aral. The delta of the Oxus is 90 miles long, including many lakes and marshes. The river is used for irrigation mainly, though it has been ascended for 280 miles by steamboats. It is thought to have once flowed into the Caspian sea, and to have twice changed its course since about 600 A. D. Its length is about 1,400 miles.

Ox'ygen, the most abundant and the most widely-distributed of all the elements, is a gas without color, odor, or taste. In its free state (mixed, not combined, with nitrogen), it composes about one-fifth of the air, and combined with hydrogen, it makes about eight-ninths of all the water on the globe. Nearly half of the earth's crust is oxygen in combination. It combines with all other elementary substances except flourine, argon, and several very rare gases resembling argon. It is necessary to animal life, and was called by early chemists "vital air." It was discovered at almost the same time, in the year 1774, by Priestley and Scheele. Lavoisier made many ingenious experiments to prove that the combustion or burning of bodies in the air was only their combination with oxygen. Combustible substances burn much more vigorously in pure oxygen than in air. Oxygen is continually given off by the leaves of plants in sunlight, and this is evidently the source of the atmospheric supply, for the gas is continually consumed by the breathing of animals, combustion, and decay.

Oys'ter, a common bivalve shelled mollusk, extensively used as food. It is related to the clam and mussel, belonging to that group of mollusks with plate-like gills (*Lamelli branchiata*). The two valves of the shell in the clam and mussel are similar; but in the oyster, one side (the lower one) is much larger. In clams and mussels the shell is closed by a pair of muscles, located at either end of the shell, but in the oyster, there is a single muscle located near the center of the shell. The dark violet spot on the inside of an oyster shell marks the position of that muscle. In structure and habits the oysters are much like the clams. The water is strained through the gills and the minute food particles are thus separated. They are carried forward to the mouth by the action of cilia. The digestive and circulatory systems are fairly well developed. The nervous system consists of three chief clusters of nerve-cells with connectives and nerve fibers. Oysters were formerly distributed along the western Atlantic coast, from the gulf of St. Lawrence to the gulf of Mexico, but are now rare north of Cape Cod. The Chesapeake bay is the center of the oyster beds. There are two kinds—a rounded form, found north, and a more southern elongated form. They are found also on the coasts of England, Europe, Japan, Cape of Good Hope, and Australia. The oyster fisheries are very extensive, and the animals are protected by laws. From May to September they are not caught, as that covers the period of breeding. The United States leads the world in the production of oysters, and by far the largest supply comes from the coast of Maryland. In 1894, more than 29,000,000 bushels were taken on the coast of the United States, valued at more than $16,500,000. Oysters were used as food by the ancient Romans, and it is claimed that the Japanese engaged in oyster culture eighteen centuries before Christ. See Brook's *The Oyster* (1891).

Ozark' Mountains, a range of mountains in Missouri. They start from the Missouri river, and crossing a part of Missouri and Arkansas, enter the Indian Territory. The Black Hills and the Washita mountains of Arkansas are parts of the range. The highest peaks have an elevation of from 1,500 to 2,000 feet.

Ozone' is the active form of oxygen which is produced by the action of electricity upon ordinary oxygen and in other ways. It is not possible to convert oxygen gas entirely into this form, but by cooling a mixture of oxygen and ozone to a low temperature the ozone may be condensed to a deep blue liquid which is unstable and readily explodes. When mixed with air, as ordinarily obtained, ozone possesses a powerful odor resembling that of diluted chlorine, and it is the most powerful oxidizing agent known, attacking india-rubber, paper, and other organic substances, and corroding mercury at ordinary temperatures. It is unstable and gradually changes to ordinary oxygen upon standing, while it undergoes this change instantly upon heating. It has been shown that ozone gas is one and one-half times as heavy as oxygen, hence chemists believe that the particles or molecules of this gas are made of three oxygen atoms, while ordinary oxygen molecules are made of two atoms. Very minute quantities of ozone probably exist in pure air, particularly that coming from the sea. The popular notion that this ozone is beneficial to health is not based on any certain facts. H. L. WELLS.

P

Pacif'ic Ocean or **South Sea** is the largest of the divisions of the ocean, including about one-half of the water surface of the globe, and covering more than one-third of the whole earth. It is 9,000 miles long, and its greatest breadth is 10,000 miles, with an area of 76,000,000 square miles. It is deeper than the Atlantic, averaging about 2,130 fathoms. There are two trade winds, blowing almost constantly, one from the northeast and the other from the southeast, on which the surface currents of the ocean depend. Along the equator is a region of calms, and also north and south of the trade winds there are belts of calms. A cold current from the Antarctic ocean flows along the coasts of South America, and a warm current from the equator flows west, dividing into two branches; one known as the Japan or north equatorial current flows north past Alaska, resembling in its effects the Gulf stream in the Atlantic; the other turns south and flows along the shores of Australia and New Zealand.

The largest American river flowing into the Pacific is the Yukon, 2,000 miles long, emptying into Bering sea; besides this are the Fraser, Columbia, Sacramento, and Colorado rivers. The rivers of South America flowing into this ocean are only mountain streams, as the Andes mountains approach so closely to the coast. The rivers of Asia, however, that flow into the Pacific are among the largest in the world, including the Amur, Hoang-ho, Yang-tse-Kiang, Mekhong, and Menam. The coasts of America and Australia bordering on the Pacific are generally mountainous, though the shores of Alaska are low and swampy, and the southern part of South America is broken with bays and islands. The gulfs of California, Panama, and Guayaquil are the most important on the American coast. The coasts of Asia are low and fertile, with many gulfs and bays and groups of islands. Bering sea, Sea of Okhotsk, Sea of Japan, Yellow sea, and China sea are formed by the peninsulas and islands on the Asiatic coast.

The Pacific ocean is remarkable for its numerous small islands and groups of islands. On the American coast are Vancouver's, Queen Charlotte, Prince of Wales, and others, in British America; Terra del Fuego, and the islands on the coast of Chile, and the Aleutian islands; the islands of Japan, Formosa, Philippine islands, Borneo, Celebes, Sumatra, and Java, New Guinea, Australia, and New Zealand are Asiatic islands, while in mid-ocean are many groups of volcanic origin. The Sandwich (Hawaiian) islands, the Ladrone islands, Marshall islands, Gilbert islands, in the North Pacific, and the New Hebrides, Society islands, Fiji islands, and the Friendly (or Tonga) islands are the principal of these island groups.

The Pacific ocean was first seen by Europeans from a mountain in Panama, by Balboa, a Spaniard. Magellan, making his way through the strait of Magellan, was the first European to sail on it, in 1520. He named it Pacific, because of its quiet waters. The first English navigator that explored it for any distance was Sir Francis Drake. The northwest passage through the Arctic ocean into the Pacific was discovered by Sir Robert McClure in 1850, and the northeast passage, in 1874, by Nordenskjold.

Pack'ard, Alpheus Spring, an American naturalist, was born at Brunswick, Me., Feb. 19, 1839, graduated from Bowdoin in 1861, and became assistant to Agassiz at Cambridge. After taking part in several scientific expeditions, he became state entomologist of Massachusetts and professor of zoölogy and geology at Brown university. He is widely known as an entomologist and zoölogist. Besides many technical papers, his publications include, *Guide to the Study of Insects* (1869), *Our Common Insects* (1873), *Zoology* (1879), *Entomology for Beginners* (1888), *Text-Book of Entomology* (1898).

Paderewski (*pad-e-rŏ'ski*), **Ignace Jan,** a Polish pianist, was born in Podolia, a province of Russian Poland, in 1860. He began his musical studies when six years old, but with very imperfect teachers, and at the age of twelve went to the conservatory at Warsaw. He made his first musical tour through Russia at sixteen, and was made a professor of music in the conservatory. Subsequently, he gave himself still more devotedly to his art, studying at Berlin and Vienna, and was appointed a professor in the conservatory at Strasburg, in 1883. While here, visiting a summer resort, to amuse his friends he once extemporized upon a theme in the style of every great musical composer, sitting down to the piano in the evening, and playing until five in the morning. He made his first public appearance as a musician at Vienna in 1887, his wonderful reputation as a performer on the piano having been made since that time. He does not depend upon his genius, great as it is, but on practice and study, shutting himself up before a concert and practicing all night. He is particularly happy in his interpretations of the works of Rubenstein, Chopin, Liszt, and Schumann. His musical compositions were nearly all written before he was five and twenty; *Polish Dances*, *Song of the Voyager*, *Menuet*, and others are among those most valued.

Padilla (*pă-dēl'yă*), **Juan Lopez de,** a popular hero of Spanish history, was appointed military commandant of Saragossa by Charles V. Soon thereafter the great rebellion, on account of burdensome taxation,

broke out, and Padilla was called to the head of the movement by the people. He was fortunate in many movements, but on April 23, 1521, he was defeated at Villalar, taken prisoner, and beheaded. His wife gathered the remaining army and held Toledo for a long time, and upon its fall retired to Portugal.

Padua (*pad'ū-ä*), one of the oldest cities of Italy, was, in the 5th century, ruled by the Huns, then exchanged between the Goths and the Eastern empire, and from 1318 to 1405 was ruled independently by a lord. In the latter year, it was conquered by Venice, which held it until 1797, when it was given to Austria, which, except from 1805 to 1814, ruled it until incorporated into Italy in 1866. The old streets are dark and narrow, and a wall still surrounds the town. The most notable building is the municipal palace (1172–1219), whose roof, 267½ feet by 89, is the largest in Europe unsupported by pillars. It has also many old churches. The university, which dates from 1222, and has 71 teachers and 1,588 students, has long been celebrated. There is no manufacturing industry. Population 83,748.

Padu'cah, the county seat of McCracken county, Ky., stands on the Ohio river about 48 miles above its mouth, and enjoys a large river and rail trade. It has flour, saw and planing mills, foundries and manufactories of soap, ice, furniture, vinegar, and tobacco. Population 19,446.

Paganini (*pä-gä-nē'nē*), **Nicolo,** a famous Italian violinist, was a porter's son, born at Genoa, Feb. 18, 1782. He early devoted himself to his instrument, practicing sometimes ten hours at a stretch, and in 1793 gave his first concert. His professional tours began in Italy in 1805, extended through Germany and Austria in 1828 and 1829, and Paris and London in 1831. He reurned to Italy very wealthy and died at Nice, his violin in his hand, May 27, 1840. See Grove's *Dictionary of Music*, Vol. II., and Engle's *From Mozart to Mario.*

Page, Thomas Nelson, famous as a writer of stories and poems in the negro dialect, was born in Hanover county, Va., April 23, 1853. He studied at Washington and Lee university, and practiced law at Richmond. He wrote his first story, *Marse Chan*, in 1884, and a collection of his writings is published under the title, *In Ole Virginny. Meh Lady* and *Marse Chan*, are two of his most popular books.

Page, William, an American painter, was born at Albany, N. Y., Jan. 23, 1811. His genius for art showed itself at an early age, and overcame his efforts to study law and theology. He received a premium from the American institute in New York for a drawing in India ink, when eleven years old, and a medal from the National academy before he was seventeen. His first portraits were those of Governor Marcy for the New York city hall, and of John Quincy Adams for Faneuil hall at Boston. In 1849, he went to Italy, spending ten years at Florence and at Rome. Besides executing, while there, such works as *Moses and Aaron on Mount Horeb* and the *Flight into Egypt*, he made copies of Titian's paintings, one of which was prevented from leaving Florence by the public officers, who insisted that it was the original picture. His full-length portrait of Farragut at the battle of Mobile was presented by a committee, in 1871, to the emperor of Russia. His portrait of Christ, and his bust of Shakespeare, and the portraits from the bust, are among his later works. He died on Staten island, New York, Oct. 1, 1885.

Pag'et, Sir **James** (Baronet), a distinguished English surgeon, was born at Yarmouth, England, in 1814; and died at London, Dec. 30, 1899. He entered the Royal College of Surgeons in 1836, became an honorable fellow in 1843, member of the council in 1865, president in 1875, and Bradshawe lecturer in 1882. He was surgeon to Queen Victoria, and to the then prince of Wales, and consulting surgeon to St. Bartholomew's hospital. He was made a baronet in 1871, and also an LL.D. by the university of Edinburgh. His works are, *Lectures on Surgical Pathology*, and *Clinical Lectures.*

Paine, Robert Treat, an American statesman, was born at Boston, March 11, 1731. He was a graduate of Harvard, and a student of theology and law. He was chaplain in 1755 of the provincial army on the northern border, and became prominent in the contests preceding the Revolution, being a delegate of the convention called in 1768 at Boston, and in 1770 managed the prosecution of Captain Preston for firing on the people. He was a member of the general assembly of Massachusetts in 1773 and 1774, and of the Continental congress from 1774 to 1778, and also a signer of the declaration of independence. He was judge of the supreme court of Massachusetts and attorney-general of that state for ten years. He died at Boston, May 11, 1814.

Paine, Thomas, a writer and free-thinker, was born in Norfolk, England, Jan. 29, 1737, and became in turn a staymaker, marine, schoolmaster, exciseman, and tobacconist. In 1774, he sailed for America. In 1776, his pamphlet *Common Sense* appeared, followed a year later by *The Crisis.* While he was serving as a private at Trenton, congress gave him the position of secretary of the committee of foreign affairs, but he lost the post in 1779, and was appointed clerk of the Pennsylvania legislature, and in 1785 was given $3,000 and the New Rochelle farm by congress. He returned to England in 1787, and in 1791–92 published his *Rights of Man*, and the famous reply to Burke's *Reflections upon*

the French Revolution. This work caused much trouble and he fled to Paris, where he was elected to the national convention which tried Louis XVI. Favoring the king, he offended Robespierre, and was imprisoned for a period of eleven months. Before his arrest, he had written Part One of *The Age of Reason*, and Parts Two and Three appeared in 1795 and 1807. In this he decried atheism and Christianity and advocated deism. He returned to America in 1802, became a drunkard, and died at New York, June 8, 1809. See Leslie Stephen's *History of English Thought in the 18th Century.*

Pais'ley, a city in Renfrewshire, Scotland, is situate on the White Cart, three miles above the Clyde and six from Glasgow. It was first heard of in 1157, was burned by the English in 1307, and suffered in the reformation in 1561. It was made a free burgh in 1488. The chief public edifices are the municipal buildings, courthouse, the county buildings, and library and museum. The manufacture of "Paisley shawls" has become extinct, but the works of cotton thread, dyeing, bleaching, tartans, woolen shawls, chemicals, starch, corn flour, carpets, and distilling and brewing flourish. Population 78,258.

Palachy (*pä-läts'kē*), **Frantisek,** a Bohemian historian, was born in Moravia, on June 14, 1798, and studied at Presburg and Vienna. He was appointed Bohemian historian in 1829, and directed to write the *History of the Bohemian People to 1526*, which is one of the greatest Bohemian literary works. He took part in the political agitation of 1848, wrote a work on the Hussite period, and died at Prague, May 26, 1876.

Palatinate (*pa-lat'in-āt*), the name of two German states united before 1623. They were called the Upper and Lower Palatinate, the Upper being what is now the kingdom of Bavaria, and the Lower lying on both sides of the Rhine, and bounded by Mainz, Treves, Lorraine, Alsace, Baden, and Würtemberg. The capital was Heidelberg. The Rhenish Palatinate was established as an hereditary possession as early as the 11th century, and in 1216 it was granted to the duke of Bavaria, and this and the Bavarian territory were held by the Bavarian house. In 1559, the Rhenish territory and the electoral vote passed to Frederick III.; afterward it passed to Frederick V., and finally to his son. In 1801, France took possession of the western part and gave the eastern to Bavaria, Nassau, and Hesse-Darmstadt. The left bank was restored to Germany in 1815, the larger part going to Bavaria, the rest being divided among other provinces. To-day, two districts of Bavaria are known as the Palatinate proper (Rheinpfalz), with an area of 2,288 square miles (population 765,991), and Upper Palatinate (Oberpfalz), with an area of 3,728 square miles (population 546,402). The capital of the latter is Ratisbon, on the Danube, population 41,471.

Pal'atine Hill. See ROME.

Paleobot'any, the science which deals with fossil plants. It is the correlative of paleontology, which deals with fossil animals. It is the function of paleobotany to work out the history of plant life on the earth. This involves the determination, as far as possible, of plants which have lived in successive ages, and the relations of those of one age to those of previous and succeeding ages. The science is as yet but poorly developed.

Paleontol'ogy, the science which deals with fossils. Vertebrate paleontology deals with the fossils of vertebrates; invertebrate paleontology, with the fossils of invertebrates; paleobotany, with the fossils of plants. All systems of rocks younger than the Archean contain fossils. Roughly speaking, they are more abundant in the later systems than in the earlier, and but few have been found in the Algonkian. The animal and plant fossils of a given system of rocks represent the fauna and flora, respectively, of the period when the system was formed. It is customary to speak of the fossils themselves as the fauna and flora; the Cambrian fauna consists of the fossils of the Cambrian system; the Lower Cambrian fauna of the fossils of the lower division of the Cambrian system; the Middle Cambrian fauna of the fossils of the middle division of the Cambrian system; and so on. It is the province of paleontology to determine (1) what fossil forms occur in the rocks of each system and in the rocks of each part of each system; (2) to determine the origin of each fauna; and (3) the relations of each fauna to its successor. The first point mentioned above involves a knowledge of the geographic diversity of animals at each stage of the earth's history. For example, there have been times when faunas were essentially cosmopolitan, that is, when the same species were essentially worldwide in their distribution. There have been other times when the faunas were colonial, that is, when geographic diversity was very great. These facts and their explanation belong to paleontology. Paleontology also involves the study of the fossils in the earlier and later parts of a system. The second point mentioned above involves the determination of the question as to whether the fauna of a given system or part of a system originated from the fauna which lived in the same region at an earlier time; or whether it represents immigrants into the region where it occurs; or, lastly, whether it resulted from the commingling of resident forms with immigrants. The third point mentioned above is akin to the second. It considers a fauna in connection with its successors and descendants, instead of in connection with its predecessors and ancestors. A complete knowledge of paleontology would

involve a complete knowledge of the living forms of each stage of the earth's history. It would do for all forms of life what history essays to do for the human race.

Paleontology is of great service in determining, or helping to determine, the age of rock formations, when their age could not be determined by other means. After the study of fossils has progressed so far as to make known the faunas of successive periods, the finding of the fossils of any one of these faunas in a given bed of rock determines the age of the bed. In making such determinations the general character of the fauna as a whole, rather than any single species, is to be relied on. Those phases of paleontology which involve the study of fossils for determining the age of formations, or for determining the relations of land and water at successive periods, or for the determination of geologic conditions of any sort are sometimes called *paleontologic geology*. Paleontologic geology, therefore, involves the study of fossils for the light they may throw on earth history. Paleontology also affords one of the chief lines of investigation for the solution of many of the problems of biological evolution. Those phases of paleontology which involve the study of fossils for the light they may throw on the history of the animal life of earth are *paleontologic zoology*. The term *paleontologic botany* would have a corresponding meaning in connection with plant life.

In a general way it is true that the animals and plants of any period are, on the whole, of higher types than those of preceding periods; but, while this is true as a general statement, it does not follow that the representatives of any class of animals in any given period are of higher type than any of the representatives of the same class at an earlier time. For example, trilobites became extinct at the end of the Paleozoic era. (See GEOLOGY.) The last of the trilobites were not higher in type than earlier representatives of the same group. The living representatives of some types of animals are less highly organized than ancient representatives of the same type. Paleontology seems to show that evolution is primarily *differentiation*, not *ascent*. Differentiation, in this connection, means the derivation of various types from a single type. Some of these derivative forms may be higher than the ancestral form, while others are lower. In the struggle for existence, the higher types, on the whole, seem to have got the better of the lower, not to the extent of annihilating the latter, but to the extent of allowing the former to dominate them. While the succession of fossils supports, in a general way, the doctrine of evolution, it has, in few cases, afforded the specific forms which demonstrate a connected line of ancestry between living forms and very ancient ones.

It is probably true that many forms of life which have lived in the past were never fossilized. It is probably true that very many forms which have been fossilized have not been found. Most fossils which are now known are the fossils of species which lived in shallow water, or in marshes and lakes. Relics of those forms of life which lived on dry land are rarely preserved. The relics of animals which live in the deep sea are likely to be preserved, but have rarely become accessible, for the fossiliferous formations of the land were, for the most part, made in shallow water. Present knowledge of ancient life is, therefore, very far from complete, and must always remain so. R. D. SALISBURY.

Palermo (*pa-ler'mō*), a seaport, archbishopric, former capital of Sicily, now the fifth city of Italy, stands on the northwest corner of the island in a valley before Mount Pellegrino. The city was first known as the Phœnician Panormus. It was successively conquered by Pyrrhus (276 B. C.), by the Romans (254 B. C.), by the Vandals (440 A. D.), by Belisarius, the Saracens, the Pisans, and the Normans. In the earthquakes of 1693, 1726, and 1823, the city suffered much. It revolted against the kings of Naples in 1820 and 1848, and was freed by Garibaldi in 1860. The streets are lined with old and picturesque buildings, of interesting architecture, the most conspicuous being the Cathedral of St. Rosalie, the royal palace, the churches of Martorana, St. John of the Hermits, and San Cataldo, the archbishop's palace, town house, and arsenal. A state university founded in 1805, has its seat at Palermo, with a teaching faculty of 61, and 1,222 attending students. The industries are insignificant, but the shipping of oranges, lemons, dried fruits, sumac, tartar, grain, oils, manna, sulphur, wine, and lemon juice are very large. Population 292,799. See Freeman's *History of Sicily*.

Pal'estine, the land of Canaan, the land of promise, the Holy Land, and the land of Israel of the Bible, was at the time of the conquest inhabited by six nations: the Canaanites, Hivites, Hittites, Ammonites, Perizzites, and Jebusites. The invaders settled in allotted lands, and the struggles for possession followed for some years, although no tribes were dispossessed. In early times the tribal distinctions were strongly preserved, but later, as spoken of in the book of Judges, the cities rose and fell, and Jerusalem became the capital of David and Solomon; but on the founding of the northern kingdom Shechem, Tirzah, and Samaria became in succession the capital. On the return of the Jews from captivity, they inhabited the territory between Jerusalem and Beersheba, and Jericho and Læchish, while the Philistines retained their lands undisturbed. Under Herod the Great, who governed the entire country, the kingdom included Galilee, unknown in the Old Testament, Samaria, Judæa, Idumæa, Peræa, Gaulonitis, Auranitis, and Trachonitis. The most populous and fertile of these provinces was Galilee. The prosperity fostered by the

Roman rulers disappeared on the conquest by Vespasian and the destruction of the temple by Titus. The second time the Jews rose in revolt, led by Bar-Cochba, the pretended Messiah, led to the bloodiest of all wars, including the siege of Jerusalem, but the revolt was put down before the fortress of Bether.

For the next hundred years the progress of Christianity was rapid, and after the conversion of Constantine and the building of the Church of the Holy Sepulchre, the history for three hundred years is the story of the church. In 614 A. D., King Chosroes, of Persia, entered Syria and was joined by the Jews, who looked to him for deliverance. They massacred 90,000 Christians in Jerusalem and burned all the buildings. Fifteen years later, the country was retaken by Heraclius, only to have it fall into the hands of the Mohammedans, in whose control it remained for four hundred years. About 640, the Mosque of Omar, the most beautiful building in the world, was built by Byzantine architects. The crusades failed to relieve the oppression, and the country went from bad to worse as regards progress, and the ruins crumbled further.

Palestine covers an area of about 6,000 square miles, is bounded on the north by the river Kasimiyeh, on the east by the Jordan, and on the west by the sea. Ranges of hills run over the entire country from east to west and, as the Bible says, it consists of desert, hills, plains, and valley. The principal elevations are Jebel Jermûk, 3,934 feet; Mounts Carmel, Ebal, Gerizim, Tell Asûr, and Râsesh Sherifeh. The valley of the Jordan begins near the Mediterranean and runs from 5 to 13 miles wide to the plain of Jericho. The country has few rivers, the Mefshukh, Namien, El Mukatta, and a few others flow into the Mediterranean, and the Yarmuk, Rukkad, Zerka, and Mojib, flow into the sea of Galilee. The summers are extremely warm and the winters cold and wet. At present, the modern spirit of improvement is at work in Palestine, roads are being built, railroads run from Jaffa to Jerusalem, and new colonies with new buildings are scattered over the entire land. The ruins are disappearing, and a modern country is springing up from the ashes. See E. Hull's, *Physical Geology and Geography of Arabia Petræa, Palestine*, etc.

Palestrina (*pă-lĕs-trē'nă*), **Giovanni Pierluigi da**, the greatest Italian composer, was born, in 1524, at Palestrina, studied at Rome and, in 1551, was made musical director of the Julian chapel of St. Peter's by Pope Julius III. In 1554, he published a collection of masses and became one of the singers of the Sistine chapel, which position he lost upon the accession of Paul IV., but in 1555 became choir master of the Lateran, and in 1561 was given a similar position in St. Maria Maggiore, which he held to the year 1571, when he returned to the Julian chapel. He reconstructed the musical service of the church, combining musical science with art, and takes a front rank in musical history. All his numerous compositions are sacred music. He died at Rome Feb. 2, 1594. See *Life*, by Baini.

Pal'et (in plants), the prominent bracts associated with the inflorescence of grasses are called "glumes," and those immediately about the individual flowers are called palets. See GRASS.

Pal'impsest, the name given to ancient parchments which have been used more than once for writing purposes. The conquest of Egypt by the Saracens cut off from Europe the papyrus which was used to write upon, and parchment could be had only in limited quantities. So, through the dark ages, old manuscripts were used, after removing the first writing upon them. Sometimes the writing was washed off with a sponge, and the parchment smoothed with pumice stone; at other times the letters were scraped away with a sharp blade. Nearly all ancient manuscripts, however, were written with an ink which could not be entirely removed, and traces of a former writing could be seen beneath the new copy. In modern times, there have been various efforts to restore these ancient writings by some chemical treatment. In this way have been found copies of the *Republic* of Cicero, the *Institutes* of Gaius, a part of the Epistle to the Romans, and other parts of the Old and New Testaments. The *Republic* of Cicero was covered by a commentary on the Psalms, written by St. Augustine.

Pal'las. See MINERVA.

Palissy (*pă-lē-sē'*), **Bernard,** the great French potter, was born near Agen, in 1509, and wandered as a glass and portrait painter until he married and settled in Saintes in 1538. While working here as a surveyor, his attention was attracted by an enameled cup, and he determined to discover the process, and, after sixteen years of continuous labor and experiment, in which he used all his resources and burned the tables and floors for fuel, he succeeded, and though imprisoned in 1562 as a Huguenot, he was released by royal edict and appointed "inventor of figulines" to the king. He removed to Paris in 1564, and, through the aid of Catherine de Medici, was saved from the massacre of St. Bartholomew. From 1575 to 1584, he gave a course of lectures on physics and natural history, demonstrating the origin of springs, the formation of fossil shells, and the best method of purifying water. In 1585, however, he was again arrested as a Huguenot and imprisoned in the Bastille, where he died in 1589. See H. Morley's *Pallissy the Potter*.

Palm, species of the great tropical family *Palmaceæ*. Palms are the tree monocotyledons, and there are more than 1,000 species. The palmetto of the Gulf states is a diminutive representative of the group. The body consists of a tall, unbranched, columnar trunk bearing at its summit a crown of immense leaves, which are pinnately or palmately veined, and often splitting so as to appear lobed or compound. The flower clusters arise from the leafy crown and are usually very large and pendent. Aside from their ornamental purposes, the palms are very useful. Notable among the useful forms, are the date palm with its pulpy fruit, the cocoanut palm with its huge seeds full of edible endosperm, the sago palm whose pith yields the starchy sago, the ivory palm whose hard endosperm is the vegetable ivory, etc. Palm honey, palm-wine, and palm-oil are also well known products. The leaves of many of the species are used for making hats, baskets, fans, etc. The palm of history and of the Bible is the date palm, while the most prized ornamental species is the royal palm.

PALMYRA PALM.

Palm'er, Edward Henry, an English orientalist, was born at Cambridge, Aug. 7, 1840, and while a boy learned the gypsy language. Afterward he acquired Italian and French. In 1860, he began the study of the Orient at Cambridge, and in 1867 graduated with third-class honors in classics. In 1868–1870, he was working for the Palestine exploration fund in surveying Sinai, and in 1871 became professor of Arabic in Cambridge, and published *The Desert of the Exodus*. In 1882, he was sent by the government to win the Sinai tribes over to Britain, and prevent the destruction of the Suez canal by Arabs, and made two expeditions, on the second of which, from Suez with Captain Gill and Lieutenant Charrington, he was betrayed and murdered at Wady Sudr, near Suez, Aug. 11, 1882. His remains, and those of his companions now repose in St. Paul's, London. See his *Life*, by Sir Walter Besant.

Palm'er, Erastus Dow, an American sculptor, was born at Pompey, N. Y., April 2, 1817. He was a joiner by trade, and made carvings first of animals and leaves in wood. Seeing a cameo head, he cut on a shell a portrait of his wife, and his success induced him to try working in marble. Two bas-reliefs, *Morning* and *Evening*, *The Sleeping Peri*, *The Angel at the Sepulchre*, in the cemetery at Albany; *Immortality*, *Faith*, and *Sappho*, also bas-reliefs, are some of his best-known works. He has executed busts of Alexander Hamilton, Washington Irving, Commodore Perry, and others, and a statue of Robert Livingstone, for the state of New York, cast in bronze. *The Landing of the Pilgrims*, in the capitol at Washington, is one of his largest works.

Palm'er, John M., a soldier and statesman of Illinois, was born at Eagle Creek, Ky., Sept. 13, 1817. He removed to Illinois when fourteen years of age and made his home at Carlinville in that state. He was admitted to the bar in 1839, and from the first took an active part in politics. He was a state senator in 1852–55, and was prominent in the organization of the Republican party in 1856. He was a member of the peace convention at Washington, Feb. 4, 1861, when it was hoped to avert war between the Federal government and the seceding states. At the outbreak of the war, he was given command of the 11th Ill., and he took part in General Fremont's Springfield expedition. He became brigadier-general in the same year, and major-general in 1862. He took part in the battles of New Madrid, Island No. 10, Corinth, and Murfreesboro. In Sherman's campaign in 1864 General Palmer had command of the 14th corps. In 1866, he had command of the military department of Kentucky. In 1868, he was elected governor of Illinois by the Republican party and served two terms. He took part in the movement to elect Horace Greeley to the presidency, and afterward acted with the Democrats. He was United States senator in 1891–97. In 1896, he was the candidate for the presidency upon the ticket of the "sound money" Democrats. He died Sept. 25, 1900.

Palm'er, Ray, an American clergyman, was born at Little Compton, R. I., Nov. 12, 1808. He graduated at Yale college, and studied theology, entering upon his pastoral work at Bath, Me. Most of his life was spent at Albany, N. Y., where he was one of the most prominent clergymen of the Congregational church. He is best known by his hymns, some of which are found in nearly every church collection, and one of which, *My Faith Looks Up to Thee*, is widely used and very popular. Besides many hymns, he has written *Closet Hours; Remember Me, or the Holy Communion; Home, or the Unlost Paradise*, a poem; and *Earnest Words*. He died at Newark, N. J., March 29, 1887.

Pal'merston, Henry John Temple, Viscount, was born near Romsey, Hants, in England, on Oct. 20, 1784, and went to the University of Edinburgh in 1800, succeeded his father as viscount in 1802, and graduated

from Cambridge in 1803. Of great ability, he was the candidate of the Tories from the college in 1806; he was defeated then and in 1807, but gained a seat in parliament in that year from the Isle of Wight. In 1811, he was elected from Cambridge and held his seat for twenty years, until he supported the reform bill. Then he successively represented Bletchingly, South Hampshire, and Tiverton. In 1809, as a tory, he was made junior lord of the admiralty and secretary of war, without a seat in the cabinet, and held the office until 1828. He left the Tory party in 1828 and entered the reform ranks, and under Earl Grey in 1830 became minister of foreign affairs, and as such adopted a policy which made England and France friends. He assisted in securing the independence of Belgium and in placing the thrones of Spain and Portugal on a constitutional basis. In 1841, he went out of office with the whigs, but returned in 1846 as foreign minister and stirred up various difficulties through his policy. In 1850, a resolution of censure was introduced in the house of lords and a resolution of confidence in the lower house, and after a debate of four days the latter was carried. In December, 1851, Palmerston was asked to resign on account of the expression of his opinions regarding the actions of Louis Napoleon, but defeated the prime minister, Lord Russell, on the militia bill in the following February. He became home secretary in 1852 and in 1855 was made prime minister, and although his government was defeated in 1857, on an appeal to the country, it stood until February, 1858, when it fell before the conspiracy bill. In June, 1859, Palmerston was made first lord of the treasury, which post he retained until his death. Among the principal events of his official career, were the American Civil war, Napoleon's war with Austria, and the Austro-Prussian war with Denmark. He died at his country seat, near Hatfield, Hertfordshire, Oct. 18, 1865. His prevailing characteristics were oblivion of self and the ardent desire to be the head of a people, not of a political party, and intense patriotism. See *Lives*, by Anthony Trollope, and the Marquis of Lorne, now Duke of Argyle.

Palmyra (*pal-mī'rä*), from 100 to 1300 A. D., a rich and beautiful city of Syria, stands in an oasis on the northern line of the Arabian desert, about 150 miles from Damascus on one side and the Euphrates on the other. It was supposed to have been founded by Solomon, but probably was a caravan station of the Arabs. During the wars between Rome and Parthia, the city acknowledged Roman supremacy and gained much by it, inasmuch as it was made the object of many favors by the Roman emperors. In 272, the attempt to found an independent empire was crushed by Aurelian, and it remained a Roman dependency until it submitted, with the rest of Syria, to the Moslems. It began its retrograde career in the 15th century, and now is but a city of ruins. The ancient inhabitants tanned leather, controlled the desert caravan trade, and mined salt, gold, and silver. See *Ruins of Palmyra*, by Wood and Dawkins.

Palo Alto (*pă'lō ăl'tō*), **Battle of,** an engagement between American troops under General Taylor, and the Mexicans led by General Arista. It took place (May 8, 1846) in the woods in the southern part of Texas, about eight miles northeast of Brownsville. The battle lasted five hours, and the Americans were victorious. Palo Alto is from the Spanish, meaning "tall timber."

Pa'lo Al'to, a town of Santa Clara county, in California, 30 miles from San Francisco, is the seat of a university founded by Leland Stanford in memory of his son. It is intended to provide education entirely free, from the kindergarten stage to the highest post-graduate work, with schools of law, medicine, and music. Several of the buildings are finished in Moorish architecture of yellow sandstone. The university, which was opened in 1891, has a faculty of 130 instructors, with about 1,400 students; has already received $20,000,000 from Senator Stanford, and has an annual income of about $600,000.

Pamir (*pă-mēr'*), the center of the central Asian highland system, is a lofty plateau with an average elevation of 13,000 feet, and unites the western ends of the Himalayas and Tian Shan mountains with the Hindu-Kush. It is crossed by mountain ranges, many peaks rising to enormous heights; and although exposed to great extremes of heat and cold and to severe snow and sand storms, the Kirghiz shepherds tend their flocks there and it is often crossed by travelers. It is full of animal and bird life, and has large rivers and lakes, including Karakul, 120 square miles, and Shivakul, 100 square miles. The Pamirs are often referred to as "the roof of the world," from their high elevation.

Pamlico (*pam'lē-kō*) **Sound,** a small arm of the Atlantic ocean on the coast of North Carolina, is separated from the ocean by long, narrow islands of sand. It is very shallow, and is about 75 miles long by from 10 to 25 miles wide.

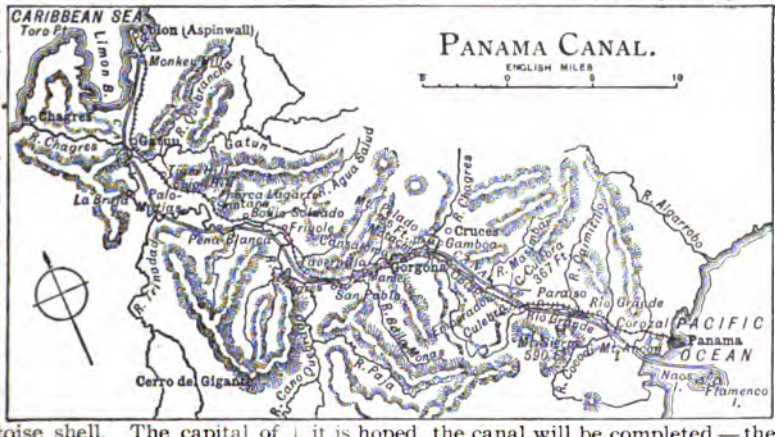
Pam'pas, a name properly applied to the large treeless plains of the Argentine Republic in South America. They rise in a series of terraces from the coast to the foot of the Cordilleras, and extend about 2,000 miles long by 500 miles broad. In the northeastern portion it is very fertile and the pampas are used almost exclusively for grazing purposes, but the rest is barren and dry, abounding in strips of desert, the soil being of sandy clay. The level districts of Peru, 180,000 square miles in extent and covered by trees, are also called pampas.

Pampas Grass, covering the pampas of the Argentine, is very hardy, beautiful in appearance, and often used for ornament. The leaves are from six to eight feet long, and the flowering stems, with large spikes of silvery-white flowers, are from ten to fourteen feet in height. The plant is now cultivated in California for the flower plumes, which are used in decorations by florists.

PAMPAS GRASS.

Pan, according to the Greek story, is considered the god of pastures, forests, and flocks and is represented as having horns, a goat's beard, a crooked nose, pointed ears, a tail, and goat's feet. The worship of Pan began in Arcadia, and in time extended all over Greece, reaching Athens last. He was worshiped by offerings of cows, goats, lambs, milk, honey, and wine. He was also supposed to have been very fond of music, being credited as the inventor of the syrinx, or pandean pipes. The Romans have identified him as their god Faunus. The story of his death, coincident with the birth of Christ, is finely treated by Milton, Rabelais, Schiller, and Mrs. Browning.

Panama (*pä-nä-mä'*), **Isthmus of,** is the narrowest part of Central America and connects Costa Rica with Colombia. It is 35 miles wide, has an area of 31,571 square miles, and now forms part of the department of Colombia. The population is 285,000. The isthmus is traversed by a range of mountains running between the Atlantic and the Pacific, and many streams, some of considerable size, notably the Tuira (160 miles), flow into both oceans. The trading ports are Aspinwall, or Colon, and Panama, and the exports are hides, tallow, indigo, caoutchouc, coffee, vanilla, gold dust, and tortoise shell. The capital of the department is Panama (population 30,000).



Panama' Canal. The plan of uniting the Atlantic and Pacific by means of a canal across the Isthmus of Darien, now Panama, was first talked of as early as 1520 and was much discussed during the 16th century. Two centuries ago definite and complete drawings were made by the Dutch, but nothing was done until Ferdinand de Lesseps called a congress of nations at Paris, in 1879, to discuss the feasibility of cutting through Panama. A concession was bought and on Feb. 28, 1881, the first force of workers landed at Colon. The canal commission estimated that the entire cost would be 800,000,000 francs, or about $160,000,000, but de Lesseps cut this down to $120,000,000 and the work proceeded. Up to 1888 immense sums of money had been borrowed and the work was not one-fifth completed, so at that year when further borrowing became impossible and the company was burdened with interest charges on the capital loaned it, owing at that time almost $370,000,000, it went into liquidation. The Colombian government granted an extension of ten years from 1893 in which to finish the work, provided that it was resumed before February, 1893. But the natural obstacles of floods, tide levels, and the death of the laborers through fevers and pestilences, on account of the climate, served to retard the work. Much of the money subscribed and borrowed, it is alleged, was foolishly spent and squandered, besides a large amount that was paid into channels that diverted it from the sources for which it was intended; so in December, 1892, a commission was appointed in France to investigate the actions of the officers and projectors of the company. As a result, certain government officers were involved in the scandal, and this led to the overthrow of the ministry. In March, 1893, a further extension of time was granted for the formation of a new company to construct the canal. According to a report (1899), this time-limit will expire in 1910. By that year, it is hoped, the canal will be completed — the cost of the revived project being put at $100,000,000. See Dr. W. Nelson's, *Five Years at Panama.*

Pan-American Exposition, a fair for the exhibit of the resources and products of the two Americas and their outlying islands, which was incorporated by the legislature of New York and endorsed by the Federal congress. According to its charter, the exhibition was held between the months of May, 1901 and Nov. of the same year, the site being Buffalo, N. Y. Congress voted $500,000 in aid of the project, and voted to loan interesting exhibits from the Smithsonian institution, the National museum, and other departments of the government. About $2,500,000 was raised in Buffalo for the purpose of equipping the exposition, and the state made a considerable appropriation. The grounds selected covered 350 acres. Power was conveyed from Niagara Falls by means of electric wires, and the exposition was successful in displaying many important electrical inventions down to date. Its main court, the Court of Fountains, was 500 feet wide by 2,000 long. The Fair was designed to embrace the main features of the Columbian Exposition which was held at Chicago, so far as they relate to the Western hemisphere. The Stadium, in which were held athletic games, seated about 10,000 persons. The president of the Exposition company was Mr. John G. Milburn, and the director-general, Mr. W. I. Buchanan, formerly minister to the Argentine Republic. A tragic incident happened early in September at the Exposition, in the attempt on the life of President McKinley, by an anarchist, named Czolgosz, which unhappily proved fatal, early on the morning of Sep. 14, 1901. In other respects the Exposition proved highly successful.

Pandora (*pan-dō'rä*), according to the Greek legend, was the first woman on earth. When Prometheus stole the fire from heaven, Zeus caused a woman to be made to bring trouble to man, and sent her to Prometheus' brother, Epimetheus. A later story relates that Pandora possessed a box in which were all the ills and troubles, which escaped on the box being opened. Still another story has it that the box contained all blessings, and Pandora, on opening it, allowed all to escape but hope.

Pan'golin, the name given to any one of the scaly ant-eaters belonging to the genus *Manis*. They are mammals, but the shape of their bodies and the presence of scales give them the appearance of reptiles. The scales are formed of cemented hairs. In some forms the tail is longer than the head and body. They inhabit Asia and western Africa and vary in length from one to five feet. They are burrowing animals and feed mainly on white ants.

Pan'icle, an open spray-like cluster of flowers, consisting of a compound raceme chiefly branching below. See INFLORESCENCE.

Pansy. See VIOLET.

Pantheon (*pan'the-on*), a temple dedicated to all the gods, has a great arched roof, lighted through one opening in the center of the dome. The Pantheon in Rome is the only ancient building that has been completely preserved. It was built by Agrippa in 27 B. C. It was consecrated as a church in 610, and is used as a burying place for eminent Italians. The Pantheon of Paris was built in 1764, and called the Church of St. Genevieve. It is also used as the mausoleum of famous men.

Panther, the name loosely applied to the leopard, but more correctly used for the stouter varieties of that animal. The puma is also called panther in America.

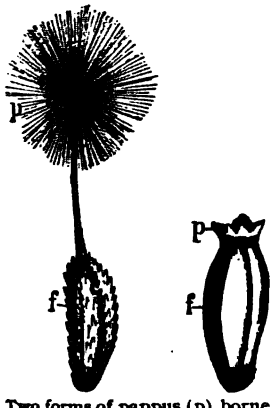
Paoli (*pä'ō-lē*), **Pasquale,** a Corsican patriot, was born in Corsica in 1726; was taken to Naples by his father in 1739, but returned to his own country to become the leader of the struggle for independence in July, 1755. He would have succeeded but that Genoa sold Corsica to France in 1768. He held out for a year against the French, but on being defeated escaped to England, where he was given a government pension. On the breaking out of the second revolution in France, he returned, became lieutenant-general and governor, and set on foot a second rebellion, hoping to form a union with England, but failed, and returned to England in 1796. He died near London, Feb. 5, 1807. See Boswell's *Account of Corsica.*

Paper takes its name, probably, from that which was first used in its place and from which it was first made — Egyptian papyrus. It was first made by laying thin slices of the cellular tissue across others, the whole moistened with Nile water and pressed, then smoothed down with ivory or shell. In the 10th and 11th centuries it was made of other fibrous matter. The Chinese encyclopedia says that the Chinese first wrote on thin strips of bamboo board, but for 300 years before and after Christ silk waste was used. The Chinese statesman, Ts'ai Lun, was the inventor of paper made of vegetable fiber. In 105 A. D. he had made paper of bark, hemp, rags, and old fishing nets. The first manufacture of rag paper in Europe was in Spain under the Moors in 1154, but soon afterward it was made in Italy, France, and Germany. It came into universal use in the 14th century. The vegetable fibers from which paper can be made are wood, bamboo, jute, straw, cornstalk, flax, hemp, besides linen and cotton rags for white paper. The pulp is ground fine and mixed with a slightly mucilaginous water in a large mash tub or drum. From the orifice in this drum the pulp or mash is slowly run into a series of very hot rollers of polished steel. The flowing of the mash is continuous, and as the sheet of pulp passes through the rollers, the rollers are tightened from time to time until the paper is thoroughly pressed, dried, and reduced to the proper thickness. The first mill in the United States was built in 1690, where Philadelphia now stands, and

to-day the paper output in America is the largest in the world, being about 2,000,000 tons a year. Next in order is England, then come France, Germany, Austria, and Italy. See works on *Paper and Paper Making*, by Hoffman, Munsell, Archer, and Dunbar.

Papier-mache (*pā-pyā'-mā-shā'*), a name applied to paper pulp, pressed and treated to resemble wood or plaster. Articles made of the pressed-pulp or of sheets of paper pasted together on a mould were first made in Persia and Cashmere in the shape of small cases, boxes, and trays. In Japan, helmets were often made in the same way. In the 18th century, one Martin began the manufacture of peculiarly varnished papier-maché snuffboxes in France, and in 1772 Henry Clay, an Englishman, received a patent for the preparation of sheets pasted together, forming door panels, tables, cabinets, and trays. The tray of sheets is formed on the mould, heated and dipped into a mixture of linseed oil and tar, then placed in the stove and afterward planed and filed. Then it is given several coats of tar and lampblack, after which it is varnished and polished by hand. The papier-maché combination has been used for doors, water pails, and even for car wheels, with success.

Pappenheim (*pāp'en-him*), **Gottfried Heinrich,** Count von, a great imperialist general in the Thirty Years' war, was born May 29, 1594, at Pappenheim, Bavaria, and at the age of twenty went over to the Catholic church. He served under the king of Poland against the Russians and the Turks, and then joined the Catholic league, defeating the Bohemians at Prague in 1620. Again, in 1626, in the Austrian service, he suppressed the peasant revolt, in which 40,000 peasants died, and then fought against the Danes, Swedes, and Saxons of the Protestant league. At Lützen, in 1632, he arrived in time to save Wallenstein from defeat by the Swedes, but was mortally wounded in the second charge and died at Leipsic, Nov. 17, 1632, pleased that Gusavus Adolphus had died just before him.



Two forms of pappus (p) borne at the summit of akenes (f).

Pap'pus (in plants), the highly modified calyx of the flowers of the *Compositæ*. As the flowers are epigynous (which see), the pappus appears to rise from the summit of the seed-like fruit ("akene"), and occurs in a great variety of forms. Sometimes it is a tuft of delicate hairs, as in the thistle and dandelion; sometimes two or more tooth-like and often barbed processes, as in tick-seed, beggar's ticks, and Spanish needles; sometimes beautifully plumose bristles, as in the blazing star; sometimes simply a cup or crown; and sometimes wanting altogether. In general, the pappus is developed to aid in the transportation of the akenes by wind or animals.

Papua (*pap'ō-ä*). See NEW GUINEA.

Papy'rus, a species of the genus *Cyperus*, which belongs to the sedge family, and contains over 600 species distributed throughout the temperate and tropical regions. The papyrus is *C. papyrus*, and is native to Egypt and Palestine. It is of interest in connection with its ancient use by the Egyptians. "The pith-like tissues of the larger flowering stems were cut into thin strips, united together by narrowly overlapping margins, and then crossed, under pressure, by a similar arrangement of strips at right angles, constituted the papyrus of antiquity." It is commonly cultivated in aquaria or in damp soil. The stem is tall and stout, from four to eight feet in height, and bearing at the summit a rosette of drooping leaves.

Para (*pä-rä'*), a city of Brazil, is 70 miles from the mouth of the river Pará. It has a fine harbor sheltered by wooded islands, which admits large vessels. It is closely built, with narrow streets, well shaded by mangoes and palms. It has street cars and telephones, and among its public buildings, a theatre, custom house, and cathedral. Here are the headquarters of the Amazonian Steamboat company, which has most of the Amazon river trade, supplying the interior towns with foreign goods and exporting india rubber, cacao, Brazil nuts, etc. The rubber exported from Para in 1898 amounted to 22,218 tons. Para is also a state or district in Brazil, with an area of 443,790 square miles, and a population of 328,455. See *Around and About South America*, by Vincent.

Paraffin (*par'a-fin*), the name given by Baron Reichenbach to a white, transparent substance obtained by him from wood tar in 1830. An English chemist, Christison, obtained the same substance, about the same time, from petroleum and called it petroline, and the French chemist, Dumas, obtained it from coal tar in 1835. Not until 1850, however, was it manufactured, and it is now used almost entirely for the making of candles, and in some branches of the arts and surgery. It is made largely from petroleum shale by the following process: The shale is broken and placed in a retort, is then distilled and treated with chemicals, after which it is cooled, when the paraffin separates as a solid and the heavy oil mixed with it is pressed out. Then the crude paraffin is treated with naphtha and the naphtha removed by further pressing after it has cooled. The paraffin is then melted and allowed to run through filters into

convenient shapes. Paraffin is obtained also from mineral wax and from the higher boiling portion of ordinary petroleum.

Paraguay (*pä-rä-gwā'*), a republic of South America, is divided by the river of the same name into eastern, or Paraguay proper, and western, or Chaco. The eastern part is bounded on the north by the Apa and Estrella rivers, on the east by the Amambay mountains and the Paraná river, and on the south by the same river. The boundaries of western Paraguay have not been fully determined. The total area is about 157,000 square miles, and the estimated population, made up of white descendants of the Spanish, Indians, and negroes, and mixtures of all, is about 432,000. The Amambay range runs from north to south, and divides the basins of the Paraguay and Paraná, whose small tributaries frequently overflow. The northern portion of the country is hilly and broken by palm-dotted plains, but the southern part is one of the most fertile regions of South America. The great forests along the rivers furnish dyewoods, valuable juices, india rubber, and a shrub known as Paraguay tea, which is in general use in South America. The crops raised are those of corn, coffee, rice, cocoa, indigo, tobacco, manioc, and sugar cane. The climate, although temperate for this region, gives life to many tropical animals and snakes. The commerce of the country, until 1880, was insignificant, but it began a steady increase in that year, and by 1899 the export of yerba-maté (Paraguay tea), tobacco, hides, oranges, timber, tanbark, and lace, had more than doubled, while the manufacture of pottery, bricks, laces, ponchos, soap, food pastes, and brandy, and tanning of leather, also increased greatly. On the grazing lands of the republic, in 1899, were 2,500,000 horned cattle, 370,000 horses, mules and asses, 300,000 sheep, goats, and pigs. The established religion is Roman Catholic, and education is free and compulsory, but of the adults only one in five can read and write.

The country was discovered by Juan Diaz de Solis, in 1515, and the first colony founded by De Mendoza, in 1535, who built the city of Asuncion and made Paraguay subject to Peru. It fell into the hands of the Jesuits, who administered its affairs until 1768, when they were expelled. In 1810, it declared its independence and elected a dictator, who held office from 1814 to 1840. Under the new constitution of 1844, Don Carlos was elected president and was succeeded by his son in 1862. This son led the war with Brazil, Argentine, and Uruguay, and was killed in battle, March 1, 1870. A new constitution, providing for two houses of congress, was proclaimed Nov. 25, 1870, upon which was begun the new presidential term of four years. The capital is Asuncion (population 45,000), and the next largest city Villa Rica (population 25,000). From Asuncion there is now a railway (156 miles in length), to Pirapó. At Asuncion there is, besides a state college, an agricultural school and model farm. See *History of Paraguay*, by Washburn, and Vincent's *Around and About South America*.

Par'aguay', a river of South America, rises in the Brazilian state of Matto Grasso, and flows southwesterly into the Paraná. Its largest tributaries are the Jauru, Cuyabá, Tacuary, Mondego, Apa, Pilcomayo, and Vermejo. The river is 1,800 miles long, and is navigable to the mouth of the Cuyabá. It was declared open in 1852, and now has steamers running upon it, carrying mail from Rio Janeiro to Cuyabá.

Parallax (*pär'al-lăks*), an optical and astronomical term used to denote the change in direction of an object due to a change in the position of the observer. This phenomenon is, perhaps, most easily observed in viewing a landscape from a railway train. When one's attention is concentrated upon any point in the landscape, all the more distant points appear to move in the same direction as the train, while the nearer points appear to move in a direction opposite that of the train. Thus, as the observer continually changes his position, being on the moving train, the direction of the point to which his attention is directed is continually changing. In the same way, if one could suddenly step from Chicago to New York, on any moonlight night, the position of the moon among the fixed stars would also suddenly change. And since the earth is rotating and carrying the observer with it, the position of the moon, or of one of the planets, among the fixed stars, depends upon the hour of the day at which the observation is made, as well as upon the latitude and longitude of the observer. Accordingly, astronomical observations of this kind are all "reduced" to the center of the earth; that is, the position of a heavenly body is given as that which it would appear to have for an observer situated at the center of the earth. Parallax of this kind is called *diurnal*. There is also a parallax due to the motion of the earth in its orbit about the sun; this is known as *annual* parallax, because it goes through all its changes in the course of one year. The principle of parallax is one of great usefulness in adjusting certain optical instruments, and in making certain optical measurements. See Young's *General Astronomy*.

Paramaribo (*par-a-mar'i-bō*), the capital of Dutch Guiana, lies on the Surinam, about ten miles from its mouth. It has broad streets, wooden houses, a governor's palace, a court of justice, two forts, and a park. Almost all the trade of Dutch Guiana is centered here. Population 31,200.

Parana (*pä-rä-nä'*), a large South American river, rises as the Rio Grande about 100 miles northwest of Rio de Janeiro. Flowing northwest and west, it unites with the

Paranahyba, and receives its name and flows southwest and south to where it is joined by the Paraguay. It then flows through Argentine, uniting with the Uruguay to form the Rio de la Plata. Its total length is nearly 2,000 miles, and it drains over 1,100,000 square miles of territory. Its longest tributaries are those named and Mogy Guassu, Tieté Paranapanema, Ivahy, Iguassu, and Salado. It is navigable for 705 miles, and has rapids over 100 miles in length immediately above the junction with the Iguassu. Paraná is also a state or department of Brazil, area 85,430 square miles, with a population of 250,000.

Parasites (*păr'ā-sīts*), among plants those which obtain food by attacking living plants or animals. The majority of parasitic plants are fungi (which see). Many of them have cultivated a very selective habit, restricting themselves to certain plants or animals, or even to certain organs. Some of the highest plants are also parasitic, as, for example, the dodder, whose thread-like body is often seen enwrapping tall herbs like skeins of yellow yarn; and the mistletoe, growing in tufts on the branches of trees. In every case the plant or animal attacked is called the "host." Sometimes the attacks are harmless, but often they are very destructive. The results of the most destructive parasites have come to be spoken of as diseases, and among them are some of the common contagious diseases.

Parch'ment, the prepared skins of sheep, goats, and calves, generally used to record wills, deeds, etc. The coarser kinds are used for drumheads and tambourines. After the hair is removed from the skin, it is stretched over a board and scraped on both sides, powdered chalk is spread on the flesh side, and then it is gone over with a pumice stone and rubbed until smooth. Unsized paper is sometimes dipped for a few moments in a solution of sulphuric acid, which renders it transparent, tough, and impervious to water. This is called vegetable parchment, and is much used. Vellum is a fine parchment made from the skins of kids, lambs, and young calves. Parchment has been used for writing upon since the earliest periods, and from the 10th to the 14th century was almost the only material that could be used for that purpose.

Pare (*pā-rā'*), **Ambroise,** the first practitioner of modern surgery, was born at Laval, France, about the beginning of the 16th century, and received his training at the Hôtel Dieu in Paris. In 1536, he joined the army, going to Italy as surgeon, and in a later campaign improved the then treatment of gunshot wounds by tying the broken arteries, instead of burning them with a red-hot iron after amputation, and made many other changes. In 1552, he became surgeon to Henry II., and afterward to Charles IX. and Henry III. His principal writings, *Five Books of Chirurgy*, have been a great aid to modern surgeons. He died at Paris, Dec. 22, 1590. See his *Life*, by Paulmier.

Parenchyma (*pa-rĕn-kĭ-ma*), the tissue in plants whose cells have thin walls, and their three dimensions approximately equal. They are the working cells of a plant, as distinct from the mechanical tissues. Parenchyma is the original tissue of every plant, and by its various modifications new tissues arise. Ordinary pith is a good illustration of dead and empty parenchyma cells.

Par'is, the capital of France and the second city in Europe, is situated on the river Seine, about 110 miles from its mouth. It is the center of a network of rivers, canals, and railroads. It is divided into two parts by the river Seine, and surrounded by a range of hills from two to five miles distant. The fortifications consist of a rampart, over 22 miles in length, with 57 gates, which it took twenty years to build, and beyond are 16 forts. The houses are built of a light-colored limestone, six or seven stories high, each floor making a distinct dwelling. Some of the finest streets are the Rue de Rivoli, Rue de Faubourg, St. Honoré, and the Rue Royale. The boulevards, or broad streets, extending in a semicircle, on the right side of the Seine, are lined with trees, seats, and stalls, while restaurants, shops, and places of amusement succeed each other for miles. The city has many beautiful squares, called places, among the finest being the Place de la Concorde, the Place de Carrousel, Place de la Bastille, and the Place Royale. In the Place de la Concorde is the obelisk of Luxor, brought from Egypt, 73 feet high, and covered with hieroglyphics. Here also was the site of the guillotine during the revolution. On the Place Vendôme stands Napoleon's column of victory. There are a number of fine triumphal arches in Paris: the Porte St. Denis, erected by Louis XIV., is adorned with basreliefs representing his victories, and the Arc de l'Etoile (Arch of the Star), begun by Napoleon in 1806, and costing $2,000,000, has the names of 384 generals and 96 victories inscribed on its walls. Ten avenues lead from this arch, one of them, the Avenue Bois de Boulogne, bordered by gardens and leading to the Bois de Boulogne park, considered one of the finest streets in the world. Another fine avenue, more like a park than a street, is the Champs Élysées (Elysian Fields). The river Seine is crossed in Paris by over 30 bridges, which communicate with spacious quays, planted with trees, affording fine walks along the banks of the river. Of these bridges, the recently-constructed Alexander III. bridge cost over a million dollars.

The Louvre, the finest modern palace in Paris, is built on the site of an old castle of the 13th century, and is connected with the palace of the Tuileries by a great picture gallery. It is filled with sculptures, paintings, and collections of Greek, Roman, and Egyp-

tian antiquities. The Tuileries was burned by the commune during the siege of Paris. The Palais Royal, the palace of the Luxembourg, the Hotel de Ville, the Palais de Justice, and the old prison, the Conciergerie, are all noted buildings. The Cathedral of Nôtre Dame, begun in the 12th century, is one of the finest specimens of Gothic architecture in the world. The Sainte Chapelle was built by Saint Louis to contain the crown of thorns and a piece of the true cross, brought by him from the Holy Land. St. Germain des Près, finished in 1163, and probably the most ancient church in Paris, contains the tomb of St. Genevieve, the patron saint of Paris. The Madeleine, the Pantheon, and l'Oratoire are some of the best known of the modern churches. The Grand Opéra is one of the most sumptuous of continental theatres.

The institutions connected with the University of France are in the Latin quarter of the city. There are found the Sorbonne, with its lecture rooms and class rooms and large library open to the public; the College of France; and a large number of colleges and lyceums, and schools of engineering, roads and bridges, charts, fine arts, etc.; and also the observatory and botanical gardens. The national library has the largest collection of books in the world, except that of the British museum. The art galleries and historical collections of the Louvre, historical museum, Hotel Cluny, the palace of fine arts, and museum of artillery, are among the richest collections in Europe.

The business of Paris is largely in articles of luxury, such as jewelry, bronzes, artistic furniture, gloves, watches, and perfumery. It is a great financial center, the Bank of France having the privilege of issuing all the banknotes in France, and the mint being located here. Paris is divided into 20 districts, governed by the préfect of the Seine, appointed by the government, and a council elected by the people.

Paris is named after the Parisii, a tribe of Gauls, whose collection of mud huts stood upon its site when conquered by the Romans. In 53 B. C., Lutetia, as it was then called, was an important Roman town; an amphitheatre of that period, capable of holding 10,000 people, has been laid bare by excavations. In the 4th century the city was called Paris, and in the 6th century it was chosen by Clovis as the seat of government, though it did not become permanently the capital of France until the 10th century. In the reign of Philip Augustus, from 1180 to 1223, Paris was, next to Constantinople, the greatest city in Europe; with its university attracting crowds of students, its churches of Nôtre Dame (partly built) and St. Chapelle, and the castle of the Louvre, the citadel of Paris. Louis XI., Henry IV., and Louis XIV. improved the city, organizing its police, drainage and sewerage systems, public schools and charities. Napoleon not only removed the marks of the terrible destruction of the revolution, but built up the city on a grander scale, with new bridges, streets, squares, arches, and public gardens, spending on its restoration more than $2,000,000 in twelve years. Yet, as late as 1834 the gutters ran through the middle of the streets; there were scarcely any side pavements, and the city was lighted by oil lamps suspended on cords across the streets. Modern Paris owes its beauty to Napoleon III. Under the direction of Haussmann his plans were carried out, broad, straight streets were built through the labyrinth of dark and narrow ones, boulevards constructed connecting all the public squares, and in place of the old houses in the heart of the town, torn down to make way for his improvements, a new city was built. Water was freely supplied, and trees and gardens and fountains sprang up everywhere, making Paris one of the greenest and shadiest of modern cities. In 1867, when the international exhibition was opened, and especially in 1900, when the exposition of that year was held, Paris was the most splendid city in Europe. The siege of Paris by the Germans in 1870, followed by the terrible destruction made by the commune, destroyed many of the finest buildings and historical monuments that can never be replaced. Under the republic, new streets have been opened; the Champs de Mars (field of Mars) changed into a beautiful garden, in which rises the Eiffel tower; a system of city railroads planned which connects the railroad stations with the heart of the city, and also the deepening of the Seine, making Paris a seaport, which will do much to make Paris the center of the world's commerce. Population 2,536,834. See *Paris in Old and Present Times*, by Hamerton.

Par'is, a Greek legendary character, sometimes called Alexander, was the second son of Priam and Hecuba, rulers of Troy. Before his birth his mother dreamed that she was to bear a firebrand which would burn the city. So his father took him to Mount Ida, where he was found after five days by Agelaus, a shepherd, after having been fed by a bear. He became reconciled to his father and afterward was made umpire by the three goddesses Juno, Minerva, and Venus as to which one was entitled to the golden apple of discord. Venus bribed him by offering him the most beautiful woman as a wife and he decided in her favor. He thereupon carried away Helen, the wife of Menelaus, and caused the Trojan war. In it he killed Achilles and was himself wounded by a poisoned arrow from which he died.

Par'is, Count de (Louis Philippe Albert d'Orleans), a descendant of the French Bourbons, son of the Duc d'Orleans, grandson of King Louis Philippe and claimant to the throne of France. He was born at Paris, Aug. 24, 1838; educated in England and

acquired considerable military experience during the Civil war in America as a member of the staff of Gen. George B. McClellan. When a boy of ten he appeared in the French chamber of deputies with his mother, but his claims were repudiated by those who came into power during the revolution of 1848. He traveled extensively in the east and in northern Africa, acquitted himself honorably in arms, and won considerable reputation as an author. He married in 1864 his cousin, the daughter of the Duc de Montpensier, by whom he had six children. He was admitted to the national assembly in 1871, at the close of the Franco-Prussian war; and that body voted the restitution of the property of his family. In 1873, he acknowledged the Comte de Chambord as the representative of the royal house of France, but on the death of that person in 1883 he united in himself the claims of both branches of the Bourbon claimants and was forced to leave France in 1886 by reason of the Expulsion act. After this he lived in England in retirement until his son tried in 1890 to enlist in the French army in violation of the law of exile. This being detected, some excitement was caused by the apparent revival of his claims. His printed works are two, one the *History of the Civil War in America*, and the other the *Condition of the English Workman*. He died at Stowe House, Buckinghamshire, England, Sept. 8, 1894.

Park, Mungo, an African traveler, was born in Scotland, Sept. 20, 1771, became an apprentice to a surgeon at Selkirk, and then studied medicine at Edinburgh, until 1791. He then became assistant surgeon on the *Worcester* and on his return offered his services to the African association and sailed from England, May 22, 1795. After learning the Mandingo language at Pisania he set out, but soon fell into the hands of a Moorish king, who made him prisoner, and from whom he escaped in 1796. In the third week of his flight he reached the Niger, which he followed to Silla and there crossed the mountains into the kingdom of Mandingo, where he lay ill for some time. He was taken back to Pisania and wrote an account of his travels in a work, *Travels in the Interior of Africa*. In 1799, he married at Selkirk, but the life of a country surgeon was too quiet for him, so in 1805 he sailed for the Niger country, in Africa, on behalf of the government. He worked up the Niger river, and with four Europeans embarked in a canoe, which was caught in the rocks at Baussa and attacked by the natives. He and his companions were drowned before any of them could escape. His account of the second voyage was published in 1815, and has been of much value to subsequent explorers. See Joseph Thomson's *Mungo Park*.

Parke, Edwards Amasa, an American theologian, was born at Providence, R. I., Dec. 29, 1808. He was a graduate of Brown university and of Andover Theological seminary. He was appointed professor of philosophy at Amherst college in 1836, going from there in 1847 to Andover seminary, where, as professor of rhetoric and afterward of theology, he spent the remainder of his life. Besides his great work as a theological teacher, he has written extensively for magazines, and edited with others the *Bibliotheca Sacra*. He has edited also several volumes, such as the *Writings of Professor B. B. Edwards*, and *Discourses on the Atonement;* and with Lowell Mason and Dr. Phelps he prepared the *Sabbath Hymn Book*.

Parke, John Grubb, General, was born near Coatesville, Penn., Sept. 22, 1827. He studied at West Point, graduating in 1849. He then began his career as topographical engineer, and his chief work was on the survey of the northwest boundary until the Civil war broke out. In November, 1861, he was appointed brigadier-general of volunteers, and went with Burnside into North Carolina, and in August following joined the army of the Potomac with his chief. He was Burnside's chief of staff at the battles of South Mountain and Antietam, and also when he took command of the whole army. General Parke commanded the ninth corps in its march to Vicksburg, after the battle of Fredricksburg. Later he had command of the left wing of General Sherman's army at Jackson, July 12, 1863, and afterward at the head of a division, he led in the defense of Knoxville. In the campaign of 1864 against Richmond he again took command of the ninth corps until Lee's surrender. In 1864, he was made major in the engineer's corps, rose to the rank of colonel in 1884, and was made superintendent of the West Point Military academy in June, 1887. Two years later he retired. He has written several works relating to his explorations and surveys, etc.

Park'er, Gilbert, Anglo-Canadian novelist and English member of parliament, was born in Canada, Nov. 23, 1862, and educated at Trinity university, Toronto, from which he holds the degree of D. C. L. He was trained to journalism in Australia, and there first began his literary and dramatic work. His novels include *Pierre and his People*, *Mrs. Falchion*, *The Trespasser*, *When Valmond came to Pontiac*, *The Seats of the Mighty*, which has also been dramatized, *The Pomp of the Lavilettes*, *The Battle of the Strong*, and *The Right of Way*.

Par'ker, Theodore, a great American preacher, was born Aug. 24, 1810, at Lexington, Mass., and graduated from Harvard Divinity school in 1836, and the next year became a Unitarian minister at West Roxbury. He was somewhat separated from the conservative Unitarians, as shown by his *The Transient and Permanent in Christianity*, and his *Discourses of Matters pertaining*

to Religion, followed by *Sermons of the Times*, all of which attracted widespread notice and comment. His complete works, in 12 vols., edited by F. P. Cobbe, were published in 1863–65. After a trip to Europe for his health, he returned in 1844 and for years preached to immense congregations at Melodeon and Music halls, Boston. He also lectured throughout the country and became an ardent anti-slavery agitator, but was stricken with bleeding of the lungs in 1859, and from Mexico went to Italy, where he died at Florence on May 10, 1860.

Par'kersburg, W. Va., the capital of Wood county, at the junction of the Ohio and the Little Kanawha rivers, 12 miles southwest of Marietta, O., and 95 miles below Wheeling, W. Va. It is on the lines of the Baltimore and Ohio, the Baltimore and Ohio South Western, and the Ohio railroads. The region about is rich in oil and natural gas, and has a considerable trade in petroleum, as well as in lumber. Its industries include oil refineries, iron foundries, boiler and machine shops, barrel factories, lumber mills, and chemical works. It has many public buildings, with a fine post office, courthouse, high and public schools, churches, banks, etc. Population 11,703.

Park'man, Francis, an eminent American historian, was born at Boston, Mass., Sept. 16, 1823. He graduated at Harvard in 1844, and after studying law two years made a journey to explore the Rocky mountains. His life among the Dakota Indians and other tribes was full of hardships, from the effects of which he suffered all the remainder of his life. His first publication was an account of this journey, called *The Oregon Trail*. His historical writings have been chiefly connected with the French power in America, beginning with *The Conspiracy of Pontiac*, (in historical order, the latest) published in 1851. After visiting France, in 1858, to study French documents on the subject, he wrote in 1865 *Pioneers of France in the New World; Jesuits in North America* in 1867; *Discoveries of the Great West* in 1869; and *The Old Régime in Canada* in 1874; *Count Frontenac and New France under Louis XIV.* in 1877; and *Montcalm and Wolfe* in 1884; and *A Half Century of Conflict* in 1892. This large amount of historical writing, done at great disadvantage from defective eyesight and feeble health, has been carefully and accurately worked out, his first visit to France being followed by several others for purposes of research. His literary style is picturesque and fascinating. He died at Jamaica Plain, near Boston, Nov 8. 1893.

FRANCIS PARKMAN.

Parks, National, a term used in the United States to designate lands set aside by the authority of the national government for public use, is applied both to historic battle fields which have been purchased, and to picturesque regions withdrawn from settlement. The most celebrated battle parks are those of Gettysburg and Chickamauga; the first of which embraces 800 acres and the second about 15 square miles. Roads have been built all through these grounds, and beautiful monuments erected to commemorate especially brave exploits or critical moments in the battles fought upon the ground. In 1895, the battle field of Shiloh, embracing 3,000 acres, was set aside by congress; but as yet this park is in its incipiency. Of the natural parks, the chief are the Yosemite and the Yellowstone. The Yellowstone Park covers about 4,480 square miles, and is 6,000 feet above the level of the sea. The mountains about it rise to a height of from 10,000 to 12,000 feet. In it are found many of the greatest natural wonders of the continent, if not of the world; geysers, hot springs, ice-cold fountains, and noble forests all conspiring to make it a "wonderland." The Yosemite Park, including the Mariposa Grove, is one of the most picturesque valleys conceivable, lying in a trough of the mountains 4,000 to 6,000 feet deep, six miles long, and from half a mile to a mile and a half wide. Through it flows the beautiful Merced river, fed by glaciers and snow fields. The Mariposa Grove is noted for its Giant Trees, the Sequoias, some of which attain a height of 275 to 375 feet and a girth of from 75 to 125 feet. All these parks are patrolled by United States troops and both flora and fauna are protected from injury.

Par'liament, the name given in England to the national assembly, and meaning a gathering for discussion, from the French word *parler* "to talk." It consists of two bodies, called the house of lords and the house of commons. The house of lords is composed of the lords spiritual or the clergy, represented by the archbishops of Canterbury and York and 32 bishops; and the lords temporal, who represent the noble families of England, Scotland, Ireland, and Wales. The titles used are duke, marquis, earl, viscount, and baron, and they are commonly called peers. The crown has the right to make new peers in addition to those who inherit their titles. In 1900, there were 593 peers on the roll of the house of lords. The chief officer of the house of lords is the chancellor, or keeper of the great seal, who acts as speaker, but does not keep order. The house of commons consists

of members elected by the people, representing counties, towns, and the universities. The larger counties and towns (or boroughs) are divided into districts, each one being entitled to a representative. There are now (1901) 670 members in the house of commons, 30 from Wales, 72 from Scotland, 103 from Ireland, and 465 from England. The chief officer of the house of commons is the speaker, chosen by the members. The members receive no salary, but have certain privileges. Parliament is called or dismissed by the government, but by law there cannot be more than three years between the closing of one parliament and the calling of a new one, and no parliament can hold its sessions longer than seven years. The decisions of parliament cannot be changed by any court of law. The houses of parliament are in Westminster, a part of London. The acts of parliament must receive the approval of the reigning sovereign, which is obtained through the ministers or members of the cabinet council. The royal assent has been given to every bill which has passed the two houses since the time of Queen Anne. The name parliament dates back to the 13th century, and the conflicts between the people and the throne, which have gradually increased the powers of parliament, are the chief theme of English history.

Par'ma, an Italian town, the former capital of the duchy of Parma, lies on the river Parma, 12¼ miles from the Po, on the Emilia road. The town is still surrounded by walls and is guarded by a citadel. Of more than 60 churches, the most noted are the cathedral, the baptistry, Madonna della Steccata, and St. John the Evangelist. Other notable buildings are the ducal palaces, library, university, music school, and museum. The principal manufactures are pianos, silks, cast iron goods, woolens, earthenware, paper, soap, etc. A state university, founded in 1512, has its seat here. Population 55,205.

Parnas'sus, a mountain in Phocis, Greece, upon whose highest peak (8,036 feet) occurred the worship of Bacchus. The mountain was the seat of Apollo and the Muses and at its base lay the seat of the oracle of Delphi and the fountain of Castalia.

Par'nell, Charles Stewart, an Irish politician, was born June 28, 1846, at Avondale, Wicklow county, Ireland, educated at Yeovil and Cambridge, and in 1874 became high sheriff of his county. In 1875, he entered parliament for County Meath as a home ruler, and in 1877–78 became notable as an obstructionist. In 1879, he was elected president of the Irish National Land league, and in 1880 visited the United States, making speeches in behalf of the movement and collecting $350,000 in its aid. On his return he was elected from counties Meath and Mayo and the city of Cork, and chose to represent the latter. On Sept. 19, 1880, at Ennis, he originated the system of boycotting an unpopular person. Gladstone caused the arrest and trial of the leaders of the party, but upon a disagreement of the jury they were set free. Then Parnell's opposition to the coercion bill caused him to be ejected from the house of commons, and the passage of the land bill almost deprived him of power. On Oct. 13, 1881, Gladstone put him in Kilmainham jail, where he remained until released through the aid of Captain O'Shea, May 2, 1882. After the land league was declared illegal, the national league arose from its disruption, and Parnell was elected its president, and began to manœuvre to throw his parliamentary strength to the conservative side. Failing in this, he carried 86 votes over to the liberals. To a great extent Gladstone's views on home rule had changed, and this brought Parnell politically close to him, but they together failed to carry the home rule bill. Thereupon the London *Times* printed its series of incriminatory articles, which caused the famous trial of 128 days, in which Parnell was cleared. He was now immensely popular and powerful, but the presentation of the freedom of the city of Edinburgh was quickly followed by disgrace on the publication of the application for divorce by Captain O'Shea, in which Parnell was made co-respondent. A decree taxing him with the costs was entered Nov. 17, 1890. The Gladstone party then demanded his retirement from politics, and gave the Irish their choice between it and Parnell. They re-elected Parnell leader, but his disgrace caused great defection in the ranks of his followers, the city of Edinburgh erased his name from the rolls, and many of his nominees were defeated. Some time after the entering of the decree of divorce, Parnell married Mrs. O'Shea. He, however, never regained his political power, and died at Brighton, England, Oct. 6, 1891. See *Parnell Movement*, by T. P. O'Connor, and *England under Gladstone*, by Justin H. M'Carthy.

Pa'ros, one of the largest islands of the Greek Archipelago of the Cyclades division, is of pyramidal shape, has an area of about 64 square miles, and a population of nearly 7,000, of which its capital, Parœkia, shelters 2,200. Its exports are wine, wool, and figs, and the quarries of celebrated Parian marble near the top of Mt. St. Elias are still worked.

Parrhasius (*par-rā'shi-us*), a great painter of ancient Greece, lived in Athens, as early as the 4th century B. C. He excelled in design, accuracy, force, and expression, and was said to be as vain and proud as he was talented.

Par'rot, a tropical bird, with short hooked bill, a thick fleshy tongue, and usually brilliant plumage. The parrot family is a large one, embracing about three hundred and fifty species. It includes macaws, cockatoos, love birds, true parrots, and parrakeets. They live usually in flocks, either in forests or on

grassy plains. Their food is mainly vegetable, consisting of fruits, seeds, buds, leaves, and the like. The Macaws, inhabiting South America, are the largest parrots. They have long pointed tails. The red and blue colors of their plumage often make inharmonious contrasts. They are noisy birds and do not talk well. The cockatoos (which see) are crested. The parrots proper have short square tails and are birds of moderate size. The parrakeets are the smaller green parrots, like the Carolina parrakeet of the southern United States. The voice of parrots is naturally harsh, but many can be taught to speak. They vary much individually in their capacity for imitating sounds. The Jako, or gray parrot of Africa, has the capacity for speaking best developed, and the yellow-headed green parrot of Mexico stands second in the list.

Par'rott, Robert Parker, an American inventor, was born at Lee, N. H., Oct. 5, 1804. He graduated from West Point, and was professor of mathematics and also of natural philosophy there. His active service in the army was in the war against the Creeks in 1834. In 1836, he was put in charge of the West Point iron and cannon foundry, and while there invented the system of rifled-guns and projectiles which bears his name. These guns were first used at the battle of Bull Run, in 1861. He died at Cold Spring, N. Y., Dec. 24, 1877.

Par'ry, Sir **William Edward,** an Arctic explorer, was born at Bath, England, Dec. 19, 1790, and entered the navy in 1806. In 1810, he commanded a ship sent to the Arctic to protect the whale fisheries, and afterward commanded five expeditions; in 1818, to find the Northwest passage; in 1819, exploring Barrow strait, Regent's inlet, and Wellington channel; in 1821 and 1824, with no results; and in 1827 with an attempt to reach the pole in sledges from Spitzbergen. He was knighted in 1829, became rear-admiral in 1852, and in 1853 was appointed governor of Greenwich hospital, which office he held to the day of his death, July 8, 1855, at Ems, Germany. See *Life*, by his son.

Par'sees is the name of the few remaining followers of the Persian religion of Zoroaster. When Zoroaster lived, or whether he lived at all, is a question, but that which remains of the alleged teachings shows that at first the belief centered in a single god, but that the god had two spirits, a reality and a non-reality, which soon led to the worship of two gods, a god of good and one of evil. The religion flourished up to the time of Alexander the Great, but after his death it declined until 212 A. D., when Artaxerxes caused the book (Zend) to be restored, and spread it throughout the land. The priests, of whom there were 40,000, became very powerful, and the religion flourished again until the defeat of the Persians in the battle of Nahavand by Omar in 641 A. D. Thereupon the greater portion became Mohammedans, but many fled, some going to India, where they now live under English rule and are much respected. In 1891, there were 89,904 Parsees in British India; and in Persia there are about 9,000 Parsis or Guebers. They eat nothing cooked by a person of another religion, and no beef or pork; prohibit polygamy, and do not bury their dead, but expose the bodies upon an iron grating. The symbol of their god is the sun and the worship is by a perpetual fire upon the altars. See Monier Williams, *Modern India.*

Par'sons, Father **Robert,** once head of the English Jesuits, was born in 1546 in Somersetshire, and went from Oxford to Baliol college, where he took his degrees and became a tutor, twice taking the oath abjuring the pope, but never taking orders in the English church. He was forced to retire from Oxford and shortly afterward, becoming a Roman Catholic, he went to Padua to study medicine, but changed his mind and went to Rome, where he offered himself to the Jesuit society in 1575 and became a Jesuit priest in 1578. In 1580, he was selected, with Campion, to do Jesuit missionary work in England, and landed there in disguise on June 11, immediately beginning vigorous, secret, and highly successful work. For a year he continued, but when Campion was taken, Parsons escaped to the continent and never returned to England. Although cautioned not to interfere in matters of state, he began to formulate plans for a Catholic invasion of England which terminated in the unsuccessful Armada, after which he organized theological seminaries at Valladolid, St. Lucas, Seville, Lisbon, and St. Omer. He died at Rome on April 18, 1610. Some of his best-known writings are *The Conference on the Next Succession to the Crown*, in which he advocated the right of the people to depose the natural heir for religious reasons, and the possession of a copy of which Parliament regarded as treasonable; *Reply to the Edict of Elizabeth; Memorial for the Reformation; His Apology* and *Manifestation of the Great Folly and Bad Spirit of Certain in England Calling Themselves Secular Priests.*

Parthenogenesis (*pär'the-no-jĕn'e-sis*). (in plants), the name applied to the production of a new plant by an egg which has not been fertilized. It is a common phenomenon in certain of the lowest plants (Thallophytes), but is very rare in the higher plants. The term is often wrongly used among seed-plants to include the formation of embryos within seeds without the presence of pollen. In most of these cases it has been proved that the embryo has not come from an unfertilized egg, but has arisen by a budding process from other cells.

Parthenon (*par'thĕ-non*), (Greek, "maiden's chamber") is the name of the temple of Athena (Pallas) in Athens, as it stands, the most perfect example of Greek architecture. Its

erection was superintended by Phidias and is built of Pentelic marble, with eight pillars in breadth and fifteen in length, being 228 feet long and 64 feet high. It stood uninjured until 1687, when it was being used as a Turkish magazine and an exploding Venetian bomb reduced it to its present state of ruin. See the Dilettanti society's *Athenian Architecture.*

Par'ties, Polit'ical, in the United States, began as early as 1787, with the discussions as to framing the national constitution. When the delegates, chosen from the several states, had agreed unanimously upon a form, there was a difference of opinion as to its merits. Prominent among its friends were Washington, Hamilton, Jay, and Madison. A series of able papers in its favor (eighty-two in number), prepared by Alexander Hamilton, of New York, were published in the *Federalist.* At once, those who sided with this view were called Federalists, and the opponents, Anti-Federalists. When Washington became President, April 30, 1789, the Federalists came into power, and Alexander Hamilton, as secretary of state, rescued the country from bankruptcy by his splendid financiering. During Washington's second term, there was a split in his cabinet, and at its close the Anti-Federalists, headed by Thomas Jefferson and Edmund Randolph, elected their candidate, Thomas Jefferson, as Vice-president, although the Federalists elected John Adams as President. Such a combination was embarrassing; but as the electoral law has been changed, it cannot again occur. The result was the defeat of Adams for a second term and the election of Jefferson to the presidency. In 1801, the Anti-Federalist administration began and the party name was changed to Democrat. This party held power until 1840, although in the election of 1824 there were four candidates in the field — all claiming to be Democrats. They were John Q. Adams, Andrew Jackson, Henry Clay, and W. H. Crawford. As no one of them was elected by popular vote, the matter was decided by the house of representatives, which placed Mr. Adams in the presidential chair. Four years later, General Jackson, the "hero of New Orleans," was elected and his administration was noted for opposition to the United States Bank, and putting into practice the doctrine that "to the victor belongs the spoils." The Whig party, which was formed in opposition to the Democratic party, and took ground in favor of a protective tariff and internal improvements, led by Daniel Webster and Henry Clay, gained its first success in the election of William Henry Harrison in 1840, but the slavery question and the death of Clay and of Webster, both in 1851, weakened the Whigs so that General Winfield Scott, in spite of his splendid military record, was defeated by Franklin Pierce, and the party ceased to exist in 1852. Several other parties arose: the Anti-Masonic party in 1826; the Liberty party in 1840, which was merged in the Free Soil party in 1848; the American party or Know-Nothings in 1854; the Republican party, made up of the Free Soil and Anti-Slavery wings of the old Whig in 1856; the Greenback party in 1866; the Constitutional Union party in 1860; the Prohibition party in 1872, and the Union Labor party in 1888. In 1856, the Democratic candidate, James Buchanan, was elected, and during his administration the Civil war began. In 1860, Abraham Lincoln was elected by the Republican party, which remained in power until 1884, when Grover Cleveland, Democrat candidate, was elected. In 1888, the Republicans elected Benjamin Harrison, and in 1892 Grover Cleveland was again elected by the Democratic party. In 1896, the Republicans elected to the presidency William McKinley, of Ohio, and in 1900 he was given a second term in the presidential chair. His chief opponent in both years for the high office was William J. Bryan, of Nebraska, the nominee of the Silver Democrat and Populist parties. The other factors in both elections were those marshaled under the banners of the Gold Democrats, the Prohibitionists, the Social Democrats, and the Socialist Labor party. In the contest of 1896, John M. Palmer, of Illinois, led the forces of the National Democrats. For Vice-president the winning men were Garret A. Hobart, of New Jersey, in 1896, and Theodore Roosevelt, governor of New York, in 1900, and now (1901) President of the United States.

Par'ton, James, an American author, was born at Canterbury, England, Feb. 9, 1822, coming to New York when five years old. He began literary work on the *Home Journal* of New York. His works are lives of Horace Greeley, Franklin, Jefferson, and Burr; *Famous Americans of Recent Times, Triumphs of Enterprise, Captains of Industry, Noted Women of Europe and America,* and a collection of the *Humorous Poetry of the English Language.* He died at Newburyport, Mass., Oct. 17, 1891.

Par'tridge, a game bird belonging to the

PARTRIDGE.

grouse family. The true partridges are Old World birds. Nevertheless, the name is

loosely applied in the United States to the ruffed grouse, which is called partridge in the north, and to the bob-white, called partridge in the south. The common partridge of England and Europe is about a foot long, of a mottled-gray color. The red-legged partridge of Europe and Asia is larger and is one of the finest game birds.

Pasade'na, a beautiful country resort of southern California, is ten miles east of Los Angeles. Its large hotel accommodates 500 people, who frequent the place as a winter resort. Population 9,117.

Pascal (*pȧs'kal*), **Blaise,** a great writer and deep thinker of France, was born June 19, 1623, in Auvergne. In 1630, he was taken to Paris by his father and carefully trained, working out difficult problems in geometry without any help, and, before he was sixteen years of age, writing a treatise on conic sections that still forms the basis of the modern treatment of the subject. Taken to Rouen in 1641, he gave himself to study and devoted much time to religion. He published his *Nouvelles Expériences sur le Vide* in 1647, and in the next year made his famous experiment in atmospheric pressure. Besides this, he invented a calculating machine. He returned to Paris in 1647, and in 1654, after the death of his father, he became converted to the Jansenists, and wrote letters in the form of tracts, which were widely distributed. His best known work is entitled, *Pensées* (Thoughts) *sur la religion.* This brought upon his head the hatred of the Jesuits. This continued until 1657, when, his health failing, he suffered until his death, at Paris, Aug. 19, 1662. See Tulloch's *Pascal* in "Foreign Classics" series (1878).

Paskevitch (*pȧs-kye'vitch*), **Ivan Feodorovitch,** count of Erivan and prince of Warsaw, a Russian general, was born May 19, 1782, at Poltava, educated in the pages' school, and, entering the army, served against the French in the war which ended in 1805. In the battles of Smolensk, Borodino, and Leipsic, and at the taking of Paris, his conduct placed him in the position of commander-in-chief against the Persians, whom he defeated in 1826–28. For this he was made count of Erivan, and afterward waged two successful campaigns against the Turks. In 1831, he suppressed the uprising at Warsaw, and was made governor. Under his rule Poland was made part of Russia. He was sent to aid Austria against the Hungarians in 1848, and in 1854 was in command of the Russian army on the Danube, but, being wounded at Silistria, he retired to Warsaw, where he died Feb. 1, 1856. See *Life*, by Tolstoi.

Passa'ic, a New Jersey city, lies on the Passaic river, eleven miles from Jersey City. It has foundries and print works and manufactories of woolens, shoddy, whips, chemicals, and india rubber. Population 27,777.

Passamaquod'dy Bay opens from the bay of Fundy on the North American coast between Maine and New Brunswick, at the mouth of the St. Croix river. It is about 15 miles long by 10 wide, and hemmed in by a cluster of islands which make an excellent harbor.

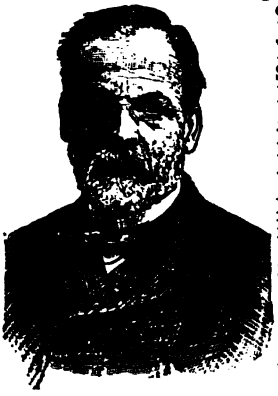
Pas'sion Flower, a species of plant almost exclusively found in the warmer parts of America, has a flower, shading from purple into light heliotrope, of five parts, with narrow lines of white from the edge of the petals meeting at the center. It received its name from the early Spanish settlers, who saw in it the crown of thorns and the five marks of the wounds of the Lord. It is a shrubby, climbing plant with lobed leaves, and some species are cultivated for the fruit, particularly the sweet calabash of the West Indies, the root of which is poisonous and acts like morphine. The roots, leaves, and flowers of some species are used as medicine.

Pass'o'ver, an annual feast of the Jews, an account of whose origin is given in Exodus xii., is the feast of unleavened bread, and originated probably when the Jews were still a wandering tribal race, and offered thanks for the year's prosperity (Gen. iv., 4). With the settlement of the Jews in Canaan, the feast and sacrifice became a fixture of the harvest time in the spring, when, after the offering of the first sheaf, the people enjoyed their corn without waiting to have their bread leavened. The celebration is accompanied by many rites spoken of in Chronicles, Ezra, and Psalms cxiii., cxviii., and in I. Cor. v., 7, and John xix., 36. See Wellhausen's *History of Israel.*

Pass'port is a paper given by a government to an individual authorizing him to leave the country, or allowing him to travel through or reside in it, affording the traveler protection. The rule has become somewhat relaxed of late, but Russia and Turkey still insist on them, while Germany requires a passport from a foreigner who wishes to reside in one place for any period of time. In England and the United States, no passports are required, but they may be obtained as a precautionary measure.

Pas'ta, Giuditta (*gwē-dēt'tȧ*), an opera-singer, was born at Como, Italy, April 9, 1798, of Jewish parents, and received her musical education at the Milan conservatory. Her first appearances on the stage were failures, and it was not until 1822, seven years later, that she scored any success. This she did at Verona, and the following year at Paris, and later at London. Her voice ranged from deep contralto to high soprano, and her chief rôles were "Medea," "Desdemona," "Semiramide," *La Sonnambula* (written for her by Bellini), "Camilla," and "Juliet" in *Romeo and Juliet.* In 1834, she retired to Lake Como, where she died April 1, 1865.

Pasteur (*päs-tür'*), **Louis,** a distinguished French chemist and biologist, was born in the department of Jura, Dec. 27, 1822. He graduated (D. Sc.) from the École Normale, in 1847, and, after holding several teaching positions, became, in 1867, professor of chemistry at the Sorbonne. He began as a chemist, but turned into microscopical work, especially along the line of bacteriology, and also ranks as a biologist. He made many discoveries of especial benefit to mankind. About 1857, he showed the process of fermentation to be due to the growth of microorganisms. In 1859, he engaged, against Pouchet, in the controversy on the spontaneous generation of life, and showed, by public experiments, the falsity of Pouchet's position, and that spontaneous generation does not occur. In 1865, he turned his attention to the diseases of the silk-worm, and, in two years, was able to arrest the ravages of a disease among them. His discoveries resulted in saving millions of dollars annually to the silk industry. His further work helped in establishing the germ-theory of disease (which see). He studied profoundly the methods of using attenuated virus for vaccination against splenic fever, hydrophobia, and other diseases. In 1888, the Pasteur institute was formally opened at Paris for the cure or prevention of hydrophobia. He received many honors, both at home and from learned societies all over the world. He died Sept. 28, 1895. See *Louis Pasteur; His Life and Labors* (1885), translated by Lady Hamilton.



M. LOUIS PASTEUR.

Patago'nia, the most southern country of South America, extends south from the Argentine republic 1,000 miles to the straits of Magellan, which separate it from Terra del Fuego. It is about 480 miles wide, has an area of about 235,550 square miles (only a fifth of this area is in Chile), and a population of about 20,000. The Andes divide the country into two parts, the eastern area of which is occupied by the Argentine republic, and the western, what little there is of it, by Chile. Hence, to-day, Patagonia is but a geographical term. The western portion is rugged and mountainous, with islands and cliffs along the Pacific coast, which give it a wild outline. The mountains are not high, but some volcanoes are notable. Minchinmavida, 8,000 feet; Corcovado, 7,510; Monte San Valentin, 12,697; and Fitzroy, 7,120, are the chief. The strip of shore along the Pacific from the Andes is so narrow that there are no rivers longer than 13 miles.

The temperature varies from 50° to 33°, summer and winter, and is very damp. Coal is mined at Punta-Arenas, where Chile has a colony and penal settlement. Eastern Patagonia is not so desolate, but has high plains in some places covered by grass, forests, and shrubs, yet along the Atlantic coast everything is wild. The rivers here are the Negro, Chubut, Deseado, Chico, Santa Cruz, and Gallegos, all rising in the Andes. Some horses and cattle are raised, and wild fowl and animals are found in some regions. The inhabitants are Indians, almost a race by themselves, who are tall and straight, very hardy and strong, and muscularly developed. They make saddles, bridles, stirrups and lassoes, and speak a language peculiar to themselves. Some Europeans are found at the settlements at Patagones, on the Chubut and the Santa Cruz. Magellan sailed along the entire coast, in 1520, and the great plain was explored by De Isla in 1535. De Gambo founded Spanish settlements in 1579 and 1580, and Drake's voyages were followed by researches by Davis, Wallace, Falkner, King, Fitzroy, Darwin, Musters, and others. Since 1870, Argentine explorers have been going over the country. See works on Patagonia by Falkner, Snow, and Musters.

Patapsco River, a river of Maryland, flowing into Chesapeake bay, 14 miles below Baltimore. It is 80 miles long, and admits large vessels as far as Baltimore.

Patents, a term used to indicate the privilege granted by a government to an inventor, of the exclusive right to his invention for a term of years. The royal grant in England was made by letters-patent or open letters, called so because they were not sealed. The system of giving patents is common in Europe and the United States, though Switzerland and Holland have no patent laws, and Prussia does not favor them. The United States patent office is a branch of the department of the interior, and has its records, models, and drawings at Washington. The first law of patents was passed in 1790, and the present law in 1870. Any invention, both new and useful, can receive a patent. It is necessary only that it should be new in the United States, its previous use in foreign countries not preventing a patent. Any person who is the first inventor of anything that admits of a patent can obtain one, whether a resident of the country or a foreigner. The patents are given for seventeen years and cannot be renewed. There are about 30,000 applications for patents every year in America, and the patent office is a very interesting place, with its thousands of models of most of the inventions of this inventive age. For the year ending June 30, 1899, there were 35,352 applications for patents in the United States patent office, Washington, D. C., and 23,550 patents

granted. The number that expired was 16,670. See *Law of Patents*, by Edmunds; and *Law of Patents*, by Robinson.

Pat'erson, a city of New Jersey, 15 miles from New York city, is situated on the Passaic river. The river curves around three sides of the city, and has a fall of 50 feet, which gives the fine water-power used in the many manufactures of the place. Its principal manufactures are silk goods and locomotives, with cotton and paper mills, factories of carpets, shawls, wire, bagging, etc. There are over a hundred silk factories, making ribbons, handkerchiefs, veils, scarfs, fringes, dress-silks, and sewing silk, giving to the city the name of the "Lyons of America." Population 105,171.

Pat'erson, William, founder of the Bank of England, was born in Dumfriesshire, Scotland, in April, 1658. He went to London, to escape, it is thought, the persecution of the Covenanters, and afterward to the Bahama islands, where he formed a scheme for a free commonwealth in Darien, known as the Darien Scheme. He made a fortune by trade in London, and planned the Bank of England, being one of its first directors. He obtained an act of the Scottish parliament, in 1695, forming the Darien company, roused the whole nation to favor his plan, and sailed with the expedition, returning, in 1699, a ruined man. In 1715, he was granted $91,205 by the government in compensation for his losses. He was active in accomplishing the union of England and Scotland. He died Jan. 22, 1719. See *Life*, by Bannister.

Pat'more, Coventry Kearsey Deighton, an English poet, was born in Essex, England, July 23, 1823, and died in Hampshire, England, Nov. 26, 1896. His first poems were published in 1844. For about twenty years he was one of the librarians of the British Museum. His best-known work is *The Angel in the House* — a poem in four parts — "The Betrothal," and "The Espousals," "Faithful for Ever," and "The Victories of Love." It has been very popular, and several new and revised editions have been published. He also edited *The Children's Garland*, and *The Autobiography of Barry Cornwall.*

Pat'mos, a small rocky island in the Ægean sea, now called Patino. It is known as the place of exile of the apostle John, and where, tradition says, he saw the visions recorded in the Book of Revelation. The monastery of "John the Divine," built in 1088, stands on a mountain in the island. The island belongs to Turkey, and is inhabited by about 4,000 Greeks, who live mostly by fishing for sponges.

Pat'na, the fifteenth city of British India, is situated in Bengal, on the river Ganges. It stretches for nine miles along the river, but has narrow streets and poor houses. The government opium factories, Patna college, Mosque of Sher Shah, a Catholic church, and a Mohammedan college, are the principal buildings. Its situation at the junction of three great rivers, the Ganges, Gandak, and Son, gives it a large trade. It exports oil seeds, cocoanuts, salt, spices, cotton, and tobacco. Patna was founded probably about 600 B. C. In 1763, it was the scene of a massacre of British prisoners, and of a mutiny in 1857. Population 170,654.

Pa'ton, John Gibson, a Scottish missionary, was born in Dumfriesshire, Scotland, May 24, 1824. He labored first as a city missionary at Glasgow, and then went to the New Hebrides, working first among the cannibal natives of Tanna. After four years the opposition of the natives forced him to leave the island. His great work was done on the island of Aniwa, where he lived for twenty years, and saw the whole population become Christians. The story of his missionary life, edited by his brother, and published in a Chicago edition in 1892, is one of the most thrilling in missionary literature.

Pa'ton, Sir Noel, a British painter, was born at Dunfermline, Scotland, Dec. 13, 1821. He studied his art at the Royal academy, London. His pictures of *Christ Bearing the Cross*, and *Reconciliation of Oberon and Titania*, together gained a prize of $1,500. Scenes from fairyland and legend, and religious allegory, have made his work familiar and have been often engraved. Among his works are *Home from the Crimea*, *Luther at Erfurt*, *The Fairy Raid*, *Gethsemane*, *Christ and Mary at the Sepulchre*, *The Man of Sorrows*, and *Thy Will be Done.* He is known also by his illustrations of the *Lays of the Scottish Cavaliers* and *The Ancient Mariner.* He has also written two volumes of poems.

Pa'triarch, Greek, the head of the Greek church. The name patriarch was given to the bishops of some of the larger divisions of "sees" of the Catholic church, and at the time of the council of Nice, there were three patriarchs, those of Antioch, Alexandria, and Rome. When the seat of empire was changed to Constantinople, its bishop was made a patriarch, and was superior to those of Antioch and Alexandria, and second only to the prelate at Rome. The Greek church arose from a division in the Catholic church, resulting from the contests between the patriarchs of Rome and Constantinople.

Pat'rick, Saint, the apostle and patron saint of Ireland, was a distinguished missionary of the 5th century. He is thought to have been born about 392. When a boy he was taken by pirates and sold to an Irish chief, who lived near the town of Broughshane, in the county of Antrim. He escaped after six years and went to France, becoming a monk. In 432, he went as a missionary to Ireland, landing at the town of Wicklow. He sailed north, hoping to convert his old master, who

killed himself, however, when he heard of Patrick's approach. A chief, named Dichu, who was converted by him, gave him his first Christian church, called Sabhall or Saul, meaning "the barn," and it is still a church bearing the same name. He is said to have founded 365 churches, baptized 12,000 people, and consecrated 450 bishops. The date of his death is in dispute, the latest period given, 470, making him about 100 years old. The only certain writings of his are his *Confessions*, and a letter written to a man named Coroticus, thought to be a Welsh chieftain, or by others a pirate who had carried off many of St. Patrick's Irish converts. See *Tri-partite Life of St. Patrick*, by Stokes.

Patt'eson, John Coleridge, an English missionary bishop, was born at London, April 1, 1827. His father was Sir John Patteson, an English judge, and his mother was a niece of Coleridge. He studied at Oxford, and became curate of Alfington in Devonshire. In 1855, he devoted himself to missionary work and sailed for New Zealand. He spent his life laboring among the Melanesian islands in the Pacific, and in 1861 was made bishop of Melanesia. He was greatly beloved by the islanders, whom he protected as far as he was able from the kidnappers of the slave trade, yet he fell a victim to their infamous traffic, being killed Sept. 16, 1871, by natives of Nukapu, one of the Santa Cruz islands, out of revenge, it is thought, for relatives carried away by the "slavers." See *Life*, by Yonge.

Patti, Adelina (*pat'ē, ad-ā-lē'nā*), a famous Italian opera singer, was born at Madrid, Feb. 19, 1843. When seven years old, she sang *Casta Diva* in New York, where her family were then living, and made her first appearance in opera in that city in 1859. Her first appearance at London in 1861 was as successful as were those in the United States, and there and at Paris and St. Petersburg, and wherever she has sung, she has been very popular and received with great enthusiasm. Her marriage to the Marquis de Caux ended in divorce, and in 1886 she married the tenor singer, Ernest Nicolini. Her Welsh home (Craig-y-nos) is near Swansea.

Patt'ison, Dora Wyndlow, known as "Sister Dora," the sister of Mark Pattison, was born at Hanxwell, in Yorkshire, England, Jan. 16, 1832. Against the wishes of her family, she began her life of labor for others as a teacher at Little Woolston, in 1861. In 1864, she joined a sisterhood, called the Good Samaritans, where she undertook the work of nursing. In hospital work her self-forgetfulness, patience, gentleness, and skill made her idolized by the rough men and women among whom she labored. The severest toil and the horrors of smallpox she braved with enthusiasm, and hundreds of the most depraved men and women were saved by her life of devotion. She died at Walsall, Dec. 24, 1878, a martyr to her work, and was followed to the grave by the whole town. A monument was built to her memory in 1886 by workingmen. See *Sister Dora*, by Margaret Lonsdale.

Patt'ison, Mark, an English writer and scholar, was born at Hornby, in Yorkshire, England, in 1813. He studied at Oxford and became a fellow of Lincoln college in 1839. His life was that of a scholar, and his standard was so high that his work largely suggests his power as a writer. He contributed articles to the *Quarterly*, the *Westminster*, and the *Saturday Review*, and wrote *Isaac Casaubon*, *Milton*, one of the best lives in the "English Men of Letters" series; edited Pope's *Essay on Man*, his *Satires and Epistles*, and the *Sonnets of Milton*. In 1861, he was made rector of Lincoln college. He died at Harrowgate, July 30, 1884. See *Memoirs*, by himself.

Pat'ton, Francis Landey, an American clergyman and educator, was born at Warwick Parish, Bermuda, Jan. 22, 1843, and educated at Knox college, Toronto. He graduated at Princeton Theological seminary in 1865. He received the degree of D.D. from Yale in 1888, and that of LL.D. from Harvard in 1889. He was ordained to the Presbyterian ministry June 1, 1865, and was pastor in New York, Nyack, and Brooklyn in succession. He became a professor in what is now McCormick Theological seminary in 1872, where he remained nine years. He was elected moderator of the general assembly in 1878. In 1881, he was elected to a chair in Princeton Theological seminary, and in 1888 to the presidency of the college of New Jersey, now the University of Princeton.

REV. DR. PATTON.

Paul was the name of five popes, of whom Paul I. and Paul II. were unimportant.

Paul III. (Alexander Far'nese) was born in Tuscany in 1468, and elected pope in 1534. Though ambitious to advance his family, making cardinals of two grandsons while they were yet boys, he was, however, a wise ruler and surrounded himself with good cardinals. His "bull," or decree of excommunication against Henry VIII. of England, issued in 1538, and the one forming the order of the Jesuits, are the most important edicts of his reign. He supported Charles V. in his struggles against the Protestant League in Germany. He died suddenly, Nov. 10, 1549. See *Lives of the Popes*, by Ranke.

Paul IV. (**Giovanni** [*gē-ō-van'nē*] **Pietro** [*pē-ā'trō*] **Caraffa**) was born at Naples in 1476. He became pope in 1555, when in his seventy-ninth year. He was strict in the punishment of heresy, establishing a censorship to examine books, and was the first to issue a list of prohibited books. He was thoughtful of the poor and just in his government, even banishing his own nephews from Rome on account of their evil conduct. He became involved in quarrels with the Emperor Ferdinand, with Philip II. of Spain, and Cosmo, grandduke of Tuscany, and his strength giving way he died Aug. 18, 1559. See *Lives of the Popes*, by Ranke.

Paul V. (**Camil'lo Bor'ghese**) was born at Rome, in 1552. He was "nuncio," or representative of the Catholic church at the Spanish court, and a cardinal under Pope Clement VIII. In 1605, he became pope. His rule was vigorous and made memorable by his long conflict with Venice, on the claim that the clergy should not be liable to trial by the common courts. The dispute was settled in 1607 by the help of Henry IV. of France. He improved Rome by new public works, the preservation of antiquities, the establishing and renewing of museums and libraries and of charitable institutions. He died Jan. 28, 1621. See *Paul the Pope and Paul the Friar*, by Trollope.

Paul, Saint (originally "Saul"), the great "apostle of the Gentiles," was born about 3 A. D., in Tarsus, according to some, but according to St. Jerome, in Giscala, in Cilicia, and taken to Tarsus in his infancy. He was a Jew of the tribe of Benjamin, and received the name Saul, changed afterward to Paul. He was in some way also a Roman citizen. He studied at Jerusalem, in the famous school of Gamaliel, and makes his first appearance in history as a persecutor of the new sect of Christians. After the persecution at Jerusalem, he set out for Damascus on the same errand. His conversion from a persecuting Pharisee to an apostle of the new religion, according to the account given in Acts, was effected by a blinding vision, which outshone the Syrian sun, and which, he affirms, was a vision of the Jesus whom he persecuted. Cured of his temporary blindness, he spent three years in retirement in Arabia, and then began at Damascus his wonderful life of labor and suffering. He and Barnabas were the first foreign missionaries of the Christian church, sailing to Cyprus, to Perga, and to Lystra, where Paul was stoned and left for dead. He sided with the Gentile converts in their struggle to free themselves from the burdens of the Jewish ceremonies, and thus won the first battle of religious liberty in the Christian church. On his second missionary journey he preached from the areopagus (Mars Hill), at Athens, to the seekers of the "unknown God," and founded the churches of Philippi, Corinth, and Thessalonica. During his third missionary journey through Galatia, Phrygia, Macedonia, and the Grecian islands, he wrote his most important group of epistles. On his fifth visit to Jerusalem, he was mobbed by the Jews, who charged him with taking a Gentile into the temple, but, claiming protection as a Roman citizen, he was sent to Felix, the Roman governor, at Cæsarea, who kept him two years in prison. Tried again by Festus, he appealed to Cæsar, and was sent bound to Rome, suffering shipwreck on the journey. Two years were spent in prison with a guard of soldiers, but he carried on his work of preaching, making converts among his guards and even in Cæsar's household. He seems to have been acquitted at Rome, and there are traces of his probable visits to Colossæ, Crete, and Nicopolis, his trial and imprisonment at Ephesus, and his second journey to Rome. His death, under Nero, probably by beheading, as he was a Roman citizen, is taught by Christian tradition; but there is nothing definite known of this. Thirteen epistles were written by him, and are found in the New Testament, some of them being letters to churches, and some to friends, in which are found those truths which make Paul the chief founder of Christian theology. "He has earned the admiration of all Christian ages, because he was great enough to overcome the prejudices of his nation and sect, and to be cursed in his own age as a renegade Jew." See *Life and Epistles of St. Paul*, by Conybeare and Howson; *Life and Work of St. Paul*, by Dean Farrar.

Pauncefote (*pŭns'fŭt*), **Julian**, Lord, an English diplomat, was born at Munich, Bavaria, Sept. 13, 1828. He was educated at Paris, Geneva, and Marlborough college, England. He became a barrister of the Inner Temple in 1852; secretary of state for the colonies in 1866; chief-justice of the Leeward islands in 1874; under-secretary of state for foreign affairs, 1882; delegate for drawing up an act relative to the navigation of the Suez canal, 1885; and minister plenipotentiary to the United States, in 1889. He has received the grand cross of St. Michael and St. George, and the grand cross of the Order of the Bath. He was a member of the International Peace conference at The Hague in 1899, and was afterward raised to the peerage. His office in Washington, on account of his distinguished services, was raised from that of a minister to that of an ambassador in 1893. He was created a baron in 1899. Died May 24, 1902.

Pausanias (*paw-sā'nē-as*), a Spartan general and nephew of Leonidas. He was in command of the Greeks in the battle of Platæa, 479 B. C., in which the Persians were defeated. He compelled the Thebans to give up the chiefs of the Persian party to him for punishment, and captured Cyprus and Byzantium. His ambition now made him become

a traitor to his country, and he entered into secret negotiations with Xerxes, hoping to rule Greece under him. He was recalled to Sparta and tried, but acquitted because of his former services to the state. A second time he renewed his intrigues and a second time was called to account by the Spartans, and again escaped punishment. His third effort to stir up the Helots to rebellion was betrayed by one of them, and Pausanias took refuge in a temple. The people blocked up the gate of the temple with heaps of stones, leaving him to die of hunger, his mother placing the first stone.

Pave'ment, a covering of stone, brick, wood, cement, or asphalt, placed on a street or road to give a hard and easier surface for travel. It is to be distinguished from the gravel and stone coating put on country roads. Pavements are mostly used in cities where the travel is large. The first thing necessary in a pavement is a good foundation. The work on the foundation depends largely upon the character of the soil and whether it is well drained or not. The best foundation is a layer of concrete, varying from six inches to twelve inches thick, according to the loads to be sustained. Of the materials used for pavement, wood is in most parts of the United States the cheapest, but it is not durable, as it rots, even when creosoted and coated with tar. Stone was formerly used in the form of small round boulders, called cobble stones, but this made such a rough pavement that it is seldom used now. Small rectangular blocks of granite or trap rock are often used. About 1880, brick pavements were introduced in the smaller cities of Illinois and Ohio, and brick is now used very extensively in different parts of the country. When the special pavement bricks of good quality are used and put on a good concrete foundation, it is one of the most satisfactory pavements for ordinary traffic, being both fairly durable and easy to travel on. Asphalt is a bituminous rock found in Trinidad, in parts of California, and other places. When heated and mixed with sand it can be used to coat a foundation on a street, and hardens into a smooth, elastic, and durable pavement for residence streets. It is used extensively in Washington and Buffalo in the United States, and in Berlin and Paris in Europe. Asphalt and brick have the advantage of medium cost and of being easily cleaned. Stone is the most durable, though it is also the most costly.

Pavia (*pä-vē'ä*), a city of northern Italy, on the Ticino river, 21 miles south of Milan. It was called the "city of a hundred towers," from its numerous square towers used as prisons, two of which, about 190 feet in height, are still standing. Its oldest church, that of St. Michael, mentioned as early as 661, is the place where the early kings of Italy were crowned; restored in 1863–76, it is now called the royal basilica. The cathedral, begun in 1488, but never finished, contains the tomb of Boëtius, and in a chapel connected with it are the ashes of St. Augustine. Near the city is the monastery of Certosa, which was built by the first duke of Milan, its church being one of the most beautiful of that era. The university, which dates from 1300, and thought to have been founded by Charlemagne, and famous in the middle ages, has now over 1,300 students, with 53 instructors, and a library of 200,000 volumes. Pavia was founded by the Gauls, sacked by Attila in 453, and by Odoacer in 476. Under the Lombards, as their capital, it became the chief city of Italy. It is memorable for the battle between the French army and the emperor's troops, fought Feb. 24, 1525, in which Francis I. of France was taken prisoner. The city was taken by the French in 1527, and in 1796 by Napoleon, and belonged to Austria after the peace of 1814. Since 1859 it has been a part of the kingdom of Italy. Population 38,722.

Pawnees (*pa-nēz'*), a tribe of American Indians, who lived on the Platte river and its branches, in Nebraska. They were divided into four bands, and were always engaged in fighting the Sioux, but have been friendly to white settlers. In 1833, and again in 1857, they gave up parts of their lands to the United States, which, however, did not protect them from the Sioux, by whom they were slaughtered, until the remnant of the tribe removed to the Indian territory in 1876. See *Pawnee Hero Stories and Folk-Tales*, by Grinnell.

Paw-Paw, called also pa-paw and custard apple, is a small tree, or shrub, found in the central and southern parts of the United States. The fruit looks somewhat like a ripe cucumber or banana, with a yellow skin, turning brown as it becomes very ripe. The flesh is soft, about the color of custard, very sweet and with large, flat, black seeds, larger than those of a watermelon. It is not often found in markets. A variety which grows in South America has a larger fruit, which is cooked with sugar and lemon before eating. Its leaves are used instead of soap, and its juice preserves meat.

Pawtuck'et, a city in Providence county, R. I., is situate on the Pawtucket river, four miles north of Providence. The river has a fall of 50 feet, which makes the city one of manufactures. It was the site in 1790 of the first cotton factory in the United States, and was for forty years the most important manufacturing town in the country. It has now cotton, woolen, haircloth, and thread factories, calico-printing works, bleaching and dyeing establishments, etc. Pawtucket was settled about 1655, formed a part of Bristol county, Conn., until 1861, and became a city in 1886. Population 39,231.

Pax'ton, Sir Joseph, an English architect, was born in Bedfordshire, England, Aug. 3, 1801. He began life as a gardener in the service of the duke of Devonshire. His care of the great glass conservatories of the duke at Chatsworth suggested to him the use of glass and iron for the building of the great exhibition of 1851. It was the first time these materials had been used for so large a building, and the effect delighted all who saw it. Paxton was knighted for his successful design. He afterward designed the Crystal Palace at Sydenham, and superintended its building, laid out the terraces, and planned the gardens. He has published the *Cottage Calendar*, which was very popular; *Paxton's Flower Garden*, and edited the *Botanical Magazine*, and a *Pocket Botanical Dictionary*. He sat in parliament for nine years, and died at Sydenham, near London, June 8, 1865.

Payne, John Howard, an American dramatist, was born at New York, June 9, 1792. His first appearance as an actor was in that city in 1809. He was a successful actor for thirty years, and also wrote several plays, of which the best known are *Brutus*, *Charles II.*, and *Clari*. The song, *Home, Sweet Home*, for which he is remembered, is in *Clari*, which was produced as an opera. The author of *Home, Sweet Home*, had no home for the last forty years of his life, and died in a foreign land, having been appointed American consul at Tunis, where he died April 10, 1852. His remains were brought to America, and buried at Washington in 1883. See *Life and Poems*, edited by Harrison; and *J. H. Payne*, by Brainard.

Pay'son, Edward, an American clergyman, was born at Rindge, N. H., July 25, 1783. He graduated at Harvard college, and after studying theology, became pastor of a Congregational church at Portland, Me., where he remained until his death, Oct. 22, 1827. He was known for his earnest piety, and was among the most prominent ministers of the period, though dying at the early age of forty-four. His publications are made up of his sermons and occasional discourses. See *Memoir*, by Cummings.

Pea'body, Andrew Preston, an American (Unitarian) clergyman, was born at Beverly, Mass., March 9, 1811. He graduated at Harvard college in 1826, studied theology, and was pastor for seventeen years of a church at Portsmouth, N. H. He was then appointed preacher and professor of Christian morals in Harvard university. For nine years he was editor of the *North American Review*, a frequent contributor to periodicals, and a well-known lecturer. He published *Lectures on Christian Doctrine*, *Christian Consolations*, *Manual of Moral Philosophy*, *Christianity and Science*, and *Christian Belief and Life*, besides over 100 sermons, tracts, and pamphlets. He died March 10, 1893.

Pea'body, Elizabeth Palmer, an American educator, was born at Billerica, Mass., near Boston, May 16, 1804. She was a sister of Mrs. Nathaniel Hawthorne and Mrs. Horace Mann. She taught in the celebrated school of Bronson Alcott, and was one of the first to introduce the methods of Froebel into American schools and to use object lessons in teaching. She was the first to establish a kindergarten in America. She published many works of an educational character, especially upon her favorite theme. Among her best-known works are *The Kindergarten in Italy*, *Letters to Kindergartners*, *Guide to the Kindergarten*, etc. She died at Jamaica Plain, Mass., Jan. 3, 1894.

Pea'body, George, an American merchant and banker, was born at South Danvers, Mass., Feb. 18, 1795. When eleven years old, he began his business life in a grocery, was next a clerk in Thetford, Vt., and afterward partner of a dry-goods house in Georgetown, D. C. This business was removed to Baltimore in 1815, and had branches at Philadelphia and New York in 1822. In 1837, he settled in London, starting a banking house, and making a large fortune, partly by investing heavily in government bonds during the Civil war. In 1851, he supplied the money needed to fit up the American department of the Great Exhibition at London. His fame rests not on his wealth, but on his benevolence, as he gave away during his lifetime five and a half million dollars. Among these gifts were $10,000 to the Grinnell expedition to the North pole, under Dr. Kane; $200,000 to found the Peabody institute at South Danvers; $50,000 to an institution at North Danvers; $1,000,000 to the Peabody institute at Baltimore; $25,000 each to Phillips academy, Andover, and Kenyon college, at Gambier, O.; $150,000 each to Harvard and Yale, and $3,500,000 as a fund for educational purposes in the south. He also spent $2,500,000 in building model homes for the poor of London, of which in 1889 there were eighteen groups in different parts of the city, accommodating 20,000 people, while the rents and interest brought in $150,000 net profit. He was offered the title of baron by Queen Victoria, but declined, asking only for "a letter from the queen, which I may carry to America and deposit as a memorial of one of her most faithful sons." The letter was given with the queen's portrait, and both are deposited in the Peabody institute, at his native town of South Danvers, now called Peabody, in honor of its illustrious citizen. He died at London, Nov. 4, 1869, his body being sent to America in an English warship. There are statues of Peabody at London and Baltimore. See *Life*, by Hanaford, and *Beneficent and Useful Lives*, by Cochrane.

Peace River, a large river of Canada, rises in British Columbia in the Rocky mountains, flowing northeast to Lake Athabasca, where

it joins the Slave river by five mouths. The delta thus formed is the most fertile part of the country. The river is 1,100 miles long, but is interrupted by rapids.

Peach, the well-known fruit of a species of Prunus (*P. Persica*) which is native to China. A well-known variety of peach is nectarine. It has long been cultivated and very many varieties have been produced. They are extensively cultivated in the warmer parts of Asia as well as in certain regions of the United States. The pericarp, that is, the transformed ovary, ripens into an outer fleshy layer and an inner stony one. Cultivation has done much in increasing the thickness of the pulpy layer. Peaches are cultivated in the United States most extensively in Maryland, Delaware, New Jersey, Pennsylvania, Michigan, and on the Pacific slope. Associated with the peach, in the genus Prunus, are the almond, plum, apricot, and cherry.

Pea'cock, a bird belonging to the pheasant family, and conspicuous for the beautiful train of the male. This train is not composed of the tail feathers, but of long feathers which overlie those of the tail, and are called tail-coverts. These, together with the tail, are capable of being erected. The peacock is a native of India and Ceylon, and is plentiful there in the forests and jungles. Their diet is varied, consisting of worms, reptiles, grain, flesh, fish, etc. These birds have been naturalized in many parts of the world. The plumage of the male combines blue, green, gold, and bronze tints. The tail-coverts are especially magnificent, with bright-colored eye-spots, and can be spread into the form of a huge fan. The blue tint is so characteristic that it has given rise to the name peacock-blue. The female is brownish and without showy tail-coverts. At first, both are alike in plumage, but the male begins to acquire gorgeous tints, and is in perfect plumage at the end of about three years. By the ancients, the peacock was called the bird of Juno.

Peale, Charles Willson, an American portrait-painter, was born at Chestertown, Md., April 16, 1741. His art education he received from a German painter and from Copley. His paintings are chiefly portraits, for which he was celebrated, among them being several of Washington. In 1785, he formed a collection of natural curiosities, founding at Philadelphia Peale's Museum. During the Revolutionary war, he commanded a company of soldiers at Trenton and at Germantown. He died at Philadelphia, Feb. 22, 1827.

Peale, Rem'brandt, an American painter, the son of Charles W. Peale, was born in Pennsylvania, Feb. 22, 1778. He painted portraits for awhile at Charleston, S. C., and then went to England and France to study his art. Besides his many portraits, he painted several historical pictures, among them the well-known *Roman Daughter;* and the *Court of Death, Notes on Italy,* and *Portfolio of an Artist,* were published by him. He died at Philadelphia, Oct. 3, 1860.

Pea'nut, the pod of species of *Arachis,* a genus which belongs to the pea family. The common species in the south is *A. hypogæa,* from South America. After flowering, the forming pod is protruded on a rigid stalk and is pushed into the soil, where it ripens its characteristic oblong, reticulated, coriaceous fruit, which contains one to three edible seeds. In the south peanuts are more commonly known as "goobers" or "goober peas."

Pear, a species of Pirus (*P. communis*) cultivated from Europe, a member of the rose family. It is associated in the same genus with the apple and quince. The peculiarity of the fruit is that the flesh consists of the transformed cup, upon whose rim the sepals, petals, and stamens arise. It is often spoken of as the calyx, but it represents a support common to all three of the outer floral organs. This type of fruit, with flesh developed from the part of the flower which surrounds the ovary, is called a "pome." The ripened ovary is represented by the "core." The pear has been cultivated from the most ancient times, and has reached a high degree of perfection. Almost innumerable varieties have been produced, each with its appropriate name. In a wild or neglected state, the branches are more or less thorny, but under cultivation the thorns disappear.

Pearl, one of the gems found in certain sea and fresh-water shells. Shells are generally lined by the animals inhabiting them with a material which gives them a smooth surface. It is laid in thin, partly transparent plates, which produce a beautiful play of colors. This lining is called mother-of-pearl, or "nacre." On opening the shells, there is sometimes found rounded portions of this nacre, which have been formed by throwing around a grain of sand, or a minute vegetable or animal growth, layers of this lining material. These are the pearls used in trade and worn as ornaments. They vary very much in size, those about as large as a pea being the best. The largest one known is two inches long and four inches around. The smallest are called seed pearls. The value depends upon the size, shape, color, and freedom from imperfections. The round ones are the best, the button-shaped next, and the drop or pear-shaped last. Pearls, when perfectly round and of extraordinary beauty, sell for large sums; the single pearl which Cleopatra is said to have dissolved and swallowed, was valued at over $400,000. The finest pearls are found close to the lips of the shell, or in the soft part of the oyster near the hinge. The largest pearl fishery in America is that of Lower California, from which come the largest and finest black pearls in the

market. The most famous pearls are from the east, especially from the Persian gulf and from Ceylon.

In the Ceylon fishery the fishing season lasts from four to six weeks. Each boat has a crew of thirteen men and ten divers, five of whom rest while the other five are diving. The work has to be done very rapidly, as the best divers cannot stay longer than eighty seconds in the water. When a boatload of oysters has been got, the cargo is landed and piled on the shore to rot, so that the pearls can be easily found. When washing out the dead animals, a close watch is kept for loose pearls, which are always the finest, while those attached to the shells are removed by pinchers or a hammer. In 1889, at Ceylon, in twenty-two days, fifty divers brought up 11,000,000 oysters. River pearls are found in fresh-water shells in Scotland, Wales, Ireland, Russia, Germany, Canada, and the United States and China. The chief river pearl fishery in the United States is in the Little Miami, in Ohio. The lining of the shells, or mother-of-pearl, is used largely in making buttons, knife and fork handles, and inlaid work on furniture. See *Gems and Precious Stones of North America*, by Kunz, and *Pearls and Pearling Life*, by Streeter.

Pearl River, a river in Mississippi, rising in the center of the state and flowing south into the gulf of Mexico. It forms a part of the boundary between Louisiana and Mississippi. The river is 300 miles long and is obstructed by sandbars and driftwood.

Pear'sons, Daniel Kimball, an American philanthropist, was born at Bedford, Vt., April 14, 1820. He graduated in medicine at Woodstock, Vt., and practiced in Chickopee, Mass., until 1857. He became a farmer in Ogle county, Ill., in 1857, but in 1860 he removed to Chicago, where he rapidly accumulated a large fortune in real estate. For some years he served the city as alderman and assisted in managing its financial budgets. He is best known through his large gifts to educational and eleemosynary institutions, the Presbyterian hospital of Chicago, and the Chicago Theological seminary being especially favored. There are few of the smaller colleges to which he has not given from $25,000 to $250,000, and his gifts run well up into the millions. He lives at Hinsdale, Illinois.

Pea'ry, Lieut. **Robert Edwin,** an American naval officer and explorer, was born at Cresson, Pa., May 6, 1856, and educated at Bowdoin college, where he graduated in 1877. He entered the United States navy as a civil engineer, Oct. 26, 1881. For several years succeeding he was engaged in surveys connected with the Nicaragua canal, but in 1886 made a trip along the coasts of Greenland in the interests of the Academy of Natural Sciences, Philadelphia. He discovered and named Melville land and Heilprin land. For his discoveries upon this trip he received medals both from American and English geographical societies. In later years, he has been almost solely engaged in Arctic explorations or in preparations for the same. In one of his Arctic winters he was accompanied by his wife, Mrs. Josephine (Diebitsch) Peary. Lieutenant Peary wrote *Northward Over the Great Ice-Cape*, and his wife wrote *My Arctic Journal*.

Peas'ants' War, an insurrection of the German peasantry, which broke out, in 1524, against the oppressions they were suffering at the hands of the nobility and clergy. For a short time it seemed that the peasants would carry everything before them, as they defeated the army sent against them by the Archduke Ferdinand, under the command of Von Waldburg; and a number of princes and knights concluded treaties with them, conceding their principal demands. But, unfortunately, the conduct of the insurgents did not accord with the moderation of their demands, as they destroyed convents and castles (more than 1,000 in all), murdered, pillaged, and committed other great excesses. In May and June, 1525, they sustained a number of crushing defeats, and were soon after completely overthrown. Multitudes were hanged in the streets, and others were put to death with the most terrible tortures. It is estimated that 150,000 lives were lost during the short period of the Peasants' war.

Peat, a substance formed by the decomposition of plants in marshes and morasses; it is also sometimes described as a kind of soil formed by the remains of mosses and other marsh plants. The remains of plants are often so well preserved in peat that their species can be easily determined; but in the northern parts of the world it is chiefly formed from certain kinds or species of bog-moss. These mosses grow in very wet places, and throw out new shoots from their upper parts, while their lower parts are decaying and forming peat, so that shallow pools are gradually changed into bogs. Moist peat is a decided and powerful antiseptic, as is shown in the preservation not only of ancient trees, leaves, and fruits, but even of animal bodies. It is claimed that in some instances human bodies have been found preserved in peat after the lapse of centuries. Peat is formed only in the colder regions of the world, as in warmer regions vegetable substances decompose too rapidly. Peat is largely used for fuel in Holland, Denmark, Scotland, Ireland, and other European countries, and efforts have been made to bring it into more general use by compressing its bulk, but although numerous machines have been invented and patented for this purpose, the enterprise has not yet proved a complete success.

Peb'ble, a small, round, water-worn stone of any kind, but with jewelers sometimes

agates—agates being frequently found as loose pebbles in streams, those of Scotland being designated as *Scotch pebbles*. Deposits of pebbles occur among the rocks of all periods; but the older pebbles are seldom loose; they are generally cemented together by iron oxide, lime, or silica, forming a pudding-stone of greater or less hardness.

Pec'cary, a small pig-like animal inhabiting the forests of the New World. There are two species, the more northern, or collared peccary, occurs as far north as the Red river in Arkansas, and ranges south to the Rio Negro of Patagonia. This species is about three feet long; it occurs singly or in small herds of eight or ten, and is comparatively harmless. The white-lipped peccary is about forty inches long, and, like the collared peccary, is covered with thick, bristly hair. Its range is between Paraguay on the south and British Honduras on the north. They occur in herds of fifty to one hundred or more, and are dangerous when excited. Both kinds live on roots, fruits, worms, and the like. In cultivated districts they are destructive to crops.

COLLARED PECCARY.

Pedagogics (*pĕd-a-gŏj'ĭks*). The term pedagogics as now used embraces the whole field of education, though formerly it was restricted to the formal phases of the subject, as school organization, methodology, and the philosophy of education.

There are certain sub-conscious forces always at work in the education of the youth as well as of the adult, which in a general way may be denominated his environments. These are the environments of the age as well as of the community. The movements and sentiments of the world at large often affect the youth in a profound manner. This is more true in these days of rapid transit and intercontinental telegraphic communication than formerly. Great economic, political, international, and social movements in any part of the globe quickly attract the attention of the reading youth, provoking more or less sympathetic discussion, with consequent enlightenment and enlargement of conceptions of the problems involved. Thus the world spirit of an age exercises influence in the education of the youth, particularly among civilized nations.

In like manner the institutions of one's own country and community, including every private and public interest which touches their lives, are active factors in the intellectual and moral development of the people. The community spirit, though influenced largely by the world spirit has a distinct and positive character of its own that in certain directions is often more potent than the formal educational machinery of the schoolroom. It affects the ideals, the language, the occupations, the tastes, the manners and customs of every one in such a way that he easily reveals his locality wherever he goes. The various institutions of civilization, the church, the home, the press, the scientific and professional associations, the political and fraternal organizations, the commercial and industrial unions, each of them making a more or less formal attempt at education in certain lines, conspire to educate the masses of the people of all classes and of all ages. The fact that these different forces are often antagonistic to each other does not in any way lessen their efficiency as educational factors.

It will readily be conceded that, however universal and effective these influences may be, at best they accomplish little in the way of a systematic development of the activities of the child. They serve rather to contribute a continuous stream of varied information, to stimulate interest, to shape sentiment and to influence conduct.

The systematic development of the activities of the child, which is the true end of formal education, can be accomplished only by the directing influence of an individual will; a will which sets up an ideal which the child is to realize and then proceeds in a methodical way to help it realize that ideal. Herein is found the specific function of the teacher. For this purpose the school is organized, equipped, and maintained. It anticipates the larger life of the community and of the adult by developing his activities so as to fit him for the wider sphere of action to which he is destined. It strives to give him that freedom in thought and action which will make him independent, self-reliant, and successful in the affairs of life.

All the activities of the child emanate from the will. The will performs a double function. It sets up ideals and then sets about to realize them. In childhood the imitative impulse is strong, and the child finds great satisfaction in taking its ideals from the concrete examples about it, imitating them with great facility. Thus it learns to walk, to talk, to do a thousand things. The ideational impulses are also active in the child and with the enlargement of its experience, under proper guidance, gradually displace the purely imitative impulses and enable the child to think and act more or less independently of the suggestions of his surroundings. Whereas his environments were molding him before, he now begins to mold his environments. This mutual reaction of the individual will and the community will, resulting in the individual will becoming the dominating power, cancels the further need for assistance from the teacher and the school.

It is the function of the teacher to encourage in every possible way the imitative or

realizing activities of the child, but it is even more important that he with great wisdom continually stimulate the exercise of the idealizing activities — perception, memory, imagination, judgment, thinking, reasoning. To this end a knowledge of the genesis, nature, and laws of development of the intellectual activities of the child is essential as a basis for successful teaching. The intimate relationship between the mental and bodily activities requires also a similar knowledge of physiology and hygiene. As the emotional and volitional life of the child gives vitality to both, the preparation of the teacher includes not only a comprehensive study of the child's physical and mental organism, but of the child in action as well; of the child at home, at his plays, at work, alone, with his fellows, in his moods, in his studies; of the normal and the abnormal child, of the child's motives, of the child in the different stages of his development and in the processes of transition from one stage to another.

With such an acquaintance with child nature, the teacher is able to enter upon a study of the underlying principles of education and of the methods by which it is to be accomplished. The following-named elementary books will prove of great value in studying the genesis, nature, function, and laws of the mental life of the child: *The Study of the Child*, Taylor; *The Mental Development of the Child*, Preyer; *Psychology and Psychic Culture*, Halleck; *Inductive Psychology*, Kirkpatrick; *Primer of Psychology*, Ladd; *The Study of Children*, Warner; *Thinking, Feeling, Doing*, Scripture; *Psychology in the Schoolroom*, Dexter and Garlic; *The Story of a Child*, Loti. See also *The Psychologic Foundations of Education*, Harris.

The nature of education appears only as one understands clearly the nature of the act of learning. The nature of the act of learning is apprehended only as one sees clearly the nature and function of the self-activity of the child. That self-activity, generically speaking, is its will. It manifests itself in feelings, cognitions, and external actions, embracing the whole range of the child's conscious life. It is incited to action by sense stimuli from within or from without the body and responds to them by making attempts to locate them in space and to discover their characteristics and relations. This effort, if successful, is called the act of learning. By it the child simply relates a present sensation or experience to a past experience, that is, connects them in the mind by virtue of their common elements and puts the new experience where it belongs. This process of transforming the new and strange into the familiar by associating, comparing, and identifying it with things already familiar, is the form which every act of learning takes and is called the apperceptive process. In this way we get the meaning of things. For an elaboration of the nature and function of the apperceptive process, see *Lange's Apperception*, De Garmo; *A Pot of Green Feathers*, Rooper; *The Study of the Child*, Taylor; *Herbartian Psychology Applied to Education*, Adams; *Talks to Teachers*, James; *Psychology*, Dewey; and almost any late work on mental science.

The act of learning in getting original knowledge may be accomplished, (*a*) by the observation of things, particularly of things in action, (*b*) by experimentation, (*c*) by means of the reasoning process. The first two may result in direct perception forming simple, or by apperception, complex mental pictures of objects. They also furnish the percepts, the images, the materials out of which the reasoning processes may elaborate general notions and principles, *induction*, or to which they may apply notions and principles already formed, *deduction*. Every notion is built up of elements derived through observation, experimentation, and reasoning. Hence the importance of cultivating habits of accuracy and many-sidedness in sense perception.

The reasoning process is the highest form of knowledge-getting and, properly exercised, continually reacts upon the other two, increasing their range and power. As a result, the growing child, at each step in his progress, is able to interpret many new experiences immediately, by simple apperception, which in a previous stage would have required even laborious reasoning.

The preparation for teaching has made great progress when the prospective teacher fully understands the details of the processes involved in the act of learning, for teaching is simply the art of stimulating and guiding the self-activity of the child to the economic and speedy accomplishment of that act. Here again appears the necessity for an intimate acquaintance with the nature and functions of the child's mental activities.

How may the teacher assist the child in the effort to learn?

As a prerequisite, it is necessary for him to discover the degree of his familiarity with the elements of the subject under consideration. If he has little or no acquaintance with it, the object should be presented to the child, and a variety of methods used to encourage him in the formation of a picture of it, and of its relations to other objects, its uses, etc. If an object is not available, the next means in order of desirability would be a model, a colored picture, a photograph, a drawing, and, lastly, a verbal description. Even though the object be at hand, the others will be found valuable, in the order given, to lead the child gradually away from the necessity of the object itself, to be able to produce a mental picture of it from its merest outline in chalk or pencil, or from a verbal description only. By means of the multitude of objects round about him, the teacher may stimulate the child's powers of observation to an almost unlimited degree.

If the child already has some acquaintance with the subject under consideration, or with its types, the teacher may help him to recognize that fact by assisting him to identify the common elements, and thus enable him the more easily and quickly to understand the new elements and form a familiar mental picture of the whole.

Should the child be familiar with some of the elements under consideration, and have sufficient ability to follow reasoning processes, the teacher may aid him by leading him carefully from one point to another until he gets its full meaning. In this way he may be taught how to trace the relations of part to the whole, of cause to effect, of identity and difference, etc.

These three attitudes or stages in which the child's mind may be, with reference to any subject, are called sense-perception, imagination, and the logical or thinking stage. As sense-perception is predominant in the early years of the child's life, that term is then applied in a general way to his method of getting knowledge, though the other two methods are rapidly coming into prominence. From six to twelve years of age, his picture-forming activities,—conception, memory, and imagination, make up a large part of his mental life. At about twelve, the power to reason abstractly is usually recognized as a strong factor in knowledge-getting, particularly if the child has been properly educated. The interdependence and interaction of these lower and higher activities in the act of learning demand quick discernment and wise adjustment on the part of the teacher to the pupil's needs. It is a great mistake to encourage the child to depend upon his lower activities, in an act of learning, when he might be using the higher.

While it is important that the child be trained to observe, investigate, and form his own ideas about the objects with which he comes in contact every day, his ability is greatly increased as he learns how to use books as aids in his efforts at knowledge-getting. It is important that books be introduced in such a way that the pupil will be constantly multiplying and enlarging his capacity to interpret his increasing range of experiences, and the problems which they involve. The act of learning as such, however important, should always be regarded by the teacher as but the process by which the self-activity of the child is developing. Each act in perception, in forming ideals, or in realizing them, reacts upon the self-activity, increasing its power and range proportionately at every step. This is the law of the reaction:—

That however objectively engaged the mind may be, the reaction upon the self-activity in exercise is the same as though it were acting directly upon itself, if that were possible.

These reactions in the act of learning, whether in forming or realizing ideals, result in habits which are always the test of mental capacity and executive skill. It is through their formation that all growth is attained, that power to solve the higher and the more complex problems of life is developed.

The importance of right methods of study, and of right methods of instruction, becomes more and more evident as this reactive effect of every act of the child is understood. For the purpose of educating the teacher properly for the responsible work of teaching, four general lines of procedure have been recognized:—

THE PHILOSOPHY OF EDUCATION.—This includes an inquiry into the fundamental principles underlying the process of knowledge-getting, the development of the self-activities, and the methods by which the teacher may co-operate with the child. The terms *theory of education*, *principles of education*, *psychology applied to education*, *institutes of education*, *psychologic foundations of education*, etc., designate similar inquiries. They all strive to discover the philosophic basis of method in education, and cover, in a general way, the nature, limits, processes, means, special elements, phases, physical culture, intellectual culture, will culture, ethical culture, æsthetic culture, and a variety of kindred problems.

The following treatises are among the most useful now published on general theoretical pedagogy: *The Philosophy of Education*, Rosenkranz; *A Manual of Pedagogics*, Putnam; *Lectures on Teaching*, Compayre; *The Philosophy of Teaching*, Tompkins; *Outlines of Pedagogics*, Rein; *Pedagogics of the Kindergarten*, Frœbel; *The Method of Recitation*, McMurry; *Theory and Practice of Teaching*, Page; *Education of the Central Nervous System*, Halleck; *Education as a Science*, Bain; *Education*, Spencer; *Lectures on Teaching*, Fitch; *Interest in its Relation to Pedagogy*, Ostermann, (translation by Shaw); *Contributions to the Science of Education*, Payne; *Education of Man*, Frœbel. The Transactions of the National Educational Association, *Barnard's American Journal of Education*, and many State Reports, contain mines of information on theoretical and practical pedagogy.

METHODOLOGY, or the art of applying educational principles in the teaching process, has called forth a great variety of treatises on special and general methods. They usually treat of the formal methods of arousing the child's interest, of presenting the subject-matter in the different stages of the child's development, of conducting the recitation, of cultivating the various physical and mental activities of the child, and of the essentials in conditions and means. Methodology usually includes more or less of a discussion of the principles involved in the methods presented. The following books treat the subject in an instructive and practical way: *Method in Education*, Roark; *School Management and Methods*, Baldwin; *School Management*, White; *Methods of Teaching*, Swett; *Talks*

on Teaching, Parker; *Hours with my Pupils*, Phelps.

School Organization and Management as a somewhat distinct problem calls for elaborate treatment. It embraces the plans of organization, the sources of revenue, the selection of school sites, the erection of school buildings, seating, ventilating, lighting, and sanitation; the courses of study, choice of textbooks, classification of pupils, preparation and examination of teachers, — the general supervision of the school, the authority of the teacher, the management of the classes, rules of conduct, modes of punishment, presentation of motives, relation of teacher and pupils, etc.

The student is referred to the following authorities for a general treatment of these problems: *School Economy*, Wickersham; *School Supervision*, Payne; *School Interests and Duties*, King; *School Management*, White; *School Management*, Kellogg; *Theory and Practice of Teaching*, Page; *Systems of Education*, Gill; *School Hygiene*, Kotelmann, (Bergstrom's translation).

The History of Education. — A liberal professional preparation for teaching is hardly possible without a comparative study of educational progress as shown in past and present educational systems. It may take either of two general forms, that of education as a whole or that of formal pedagogy in particular. If the former, the field includes a history of the growth of all branches of learning and of the various institutions of civilization in general; if the latter, it is limited to the development of educational doctrine and the growth of systems and methods. There are commonly recognized five great epochs in educational history: the Oriental, the Classical, Christian before the Reformation, the Reformation, and the Modern Epoch. Each epoch is rich in instructive material, throwing light upon nearly every problem which the teacher meets and helping him to a more comprehensive view of the methods by which they may be solved.

The following are among the standard texts on this subject: Compayre, Painter, Seeley, and Williams. See also Boone's *Education in the United States*, Swett's *American Public Schools*, Klem's *European Schools*, Quick's *Educational Reformers*, Laurie's *Rise and Early Constitution of Universities*, Lang's *Great Teachers of Four Centuries*, Browning's *Educational Theories*, Butler's *Great Educators*, Winship's *Great American Educators*, and the histories of education in the different states of the Union published by the bureau of education.

The methods of teaching as well as the subject matter must vary with the age and capacity of the pupil. In the earlier years, nature study supplies an abundance of material which may be used to introduce the elements of knowledge. The ability to correlate these elements in a systematic way and in the advancing grades gradually to differentiate them into the particular branches of knowledge developing from them, requires great skill on the part of the teacher.

The following brief survey of nature study and a few other subjects, together with suggestions for teaching them, will serve to illustrate scientific method.

Nature Study. — The environments of the child, as already explained, constantly stimulate sense perception and provoke inquiry. They are always arousing him to see and hear and smell and taste and touch. The satisfaction he gets in exercising his senses begets increasing desire to their further exercise and his ability to discriminate grows rapidly every day. Curiosity and wonder spur him to find out what he can about everything he meets. These experiences are his mental food as well as the means of his physical development. Parents usually pay too little regard to mental culture in the first five years of the child's life, little realizing its relation to the after-life, though his eagerness to know usually accumulates a great fund of child knowledge and even child skill before he enters school. These years powerfully affect his life habits of investigation, of thinking, of talking, of language, of acting.

On entering school he has already made considerable progress in getting acquainted with the animate and inanimate objects about him. He is usually bubbling over with interest in everything he meets, particularly with those things that give sense pleasure and strike him as strange and novel. His knowledge is already of things in nature as well as of things in the household and about his father's work. This knowledge furnishes a fine starting point for his school work and suggests the wisdom of continuing it on the very lines so well calculated to maintain and enlarge his interests and encourage him to study. Nature study, then, may rightly engross a large part of the course of study for the lower grades. It serves to introduce the elementary work in the other subjects usually included in the higher grades and thus provides for that gradual transition to their more abstract phases and their more complex problems which is demanded by all scientific method. The teacher should plan the nature work so that it not only extends the child's range of experiences, but anticipates in a logical way the deeper and broader inquiries which he is to make later.

While there should always be method and system on the side of the teacher, there should always be relative simplicity and variety on the side of the child. The material should be selected with a view to the continual exercise and development of the perceptive activities, of observation, of understanding, of memory, of judgment, and of language. There is abundant material in every locality for use in this study. The teacher's individuality and ingenuity will enable him to utilize the

children in gathering the material and the data for talks and studies. In the higher grades the inquiries should be exhaustive and should assume a more strictly scientific form.

In September or October there are many interesting and instructive features of plant life which furnish the material in sufficient variety for several lessons: the more common autumn fruits of the locality, wild and cultivated, with a study of their form, texture, flavor, name, and use, etc; the autumn leaves and flowers with a study of their form, color, etc.; the autumn seeds, their forms, methods of distribution by winds, by animals, by water, etc. The animal life of these months is full of interest for young and old. The birds which have summered in the locality are going south and others with strange plumage are coming in from the north on their way further south or to spend the winter here. Insects are gradually disappearing in a variety of ways, some going into winter quarters to appear in new forms in the spring, others hiding away in the trees, in the earth, or elsewhere, while countless multitudes deposit their eggs and die. The thickening of the coats of the wild and domestic animals should be carefully observed now and in the month following. Clouds, rain, dew, frost, changes in temperature, direction of the wind, etc., will interest the child here and every month in the year.

In November and December nature study finds ample outdoor range in discovering how the plants have prepared for winter, how the buds are sealed up, where the leaves have gone, what animals still remain in the locality and how they live, what the streams are doing, where the fish and other water animals have gone, what the farmers are doing, etc. They are also good months for studying further the collections of fruits, seeds, leaves, grasses, etc., made in other months. Why are the days so short now? Why is the sun so far north? Why are fruits and vegetables beginning to rise in price in the markets?

The weather is a fruitful theme during January, February, and March, but there is much also to engage attention in the lines mentioned for the preceding months. A simple study of the forms and modes of movement of domestic and of wild animals will make a few attractive lessons. These are good months for the study of the various forms of water, and for making simple experiments in light, heat, electricity, etc. Note also later on the signs of springtime in the growing length of the days, in the disappearance of frost and snow, in the swelling and opening of certain kinds of buds, in the flowing of the sap in the trees, in the appearance of an occasional last year's animal, in the song of the robin or the quick cry of the redbird, in the buzzing of venturesome bees, in the work about the house and the farm.

April, May, and June conspire to furnish a world of material to attract and interest childhood. The studies should include the germination of seeds, the unfolding of leaves, the opening of the flowers; the parts of the plant, of the leaves and of the flowers, etc.; the various animals that cover the earth and skim the air, the moulting of the birds, the metamorphosis of the grasshopper, the butterfly, the frog, the building of nests, the swarming of the bees, animal foods. They should also include all kinds of work about the farm and home and should keep the child in close touch with ploughing time and seed time, and harvest, with the pests the farmer fears, the friends he should protect, etc.

July and August, as well as a great part of June, are months in which the child is usually out of school, but if the teaching during the other months is successful, these months also will have much in experiences upon which he will find pleasure in drawing as school opens in September.

Nature study includes the various parts and functions of the child's body, as well as of animals in general, and should make the child acquainted with the conditions essential to good health and to the development of physical strength and skill. It also includes a study of the topography of the locality, the soil, the rocks, the mineral deposits, the springs and streams, together with the forces which have shaped and are shaping the land. Excursions to other localities will be invaluable in adding zest to every phase of the study.

Success in directing nature study depends greatly upon the teacher's ability to select and arrange these materials in such a way as to bring them within the growing capacity of the child and yet to stimulate perpetual effort. All of the foregoing and much more may readily be covered in a simple way in the first three years of a child's school life. The enlargement of the scope of the study in the following years gradually differentiates into geography, botany, physiology, physics, chemistry, meteorology, astronomy, zoology, and geology.

The grade teacher's preparation therefore includes a fair knowledge of these subjects and familiarity with the natural history of the locality. The following books will prove helpful in getting acquainted with the possibilities of nature study. They cost but a small sum and will serve as helpful guides in almost any locality. The list is made sufficiently large to show the range of books within the teacher's reach: *In Nesting Time*, Olive Thorne Miller; *Animal Life*, Bass; *Four Feet, Two Feet, No Feet*, Laura Richards; *Short Stories of Our Shy Neighbors*, Mrs. A. K. Kelly; *Country Cousins*, Ingersoll; *My Saturday Bird Class*, M. Miller; *Neighbors with Claws and Hoofs*, Johonnot; *Neighbors with Wings and Fins*, Johonnot; *My Land and Water Friends*, Bamford; *Little Folks in Feathers and Fur*, Olive Thorne Miller; *Up and Down the Brooks*, Bamford; *Bird Ways*, Miller; *Population of*

an Old Pear Tree, Van Bruyssel; *Plant Life*, Bass; *The Fairy Land of Flowers*, Pratt; *Little Flower Folks*, Pratt; *Stories of the Trees*, Dyson; *From Seed to Leaf*, Newell; *Flower and Fruit*, Newell; *Plants and Their Children*, Mrs. W. S. Dana; *Geological Story*, J. D. Dana; *The Rollo Books*, Abbott; *Real Fairy Folks*, Meyer; *Simple Experiments in Science Teaching*, Bower; *The Fairy Land of Science*, Buckley; *Stories Mother Nature Told Her Children*, Andrews; *Kindergarten Stories and Morning Talks*, Wiltse; *Seven Little Sisters*, Andrews; *Madam How and Lady Why*, Kingsley; *Nature Myths and Stories for Childhood*, Cooke; *Seaside and Wayside*, Wright; *Cat Tails and Other Tales*, Hawliston; *Home Studies in Nature*, Treat; *Brooks and Brook Basins*, Frye; *Nature Study for Common Schools*, Jackman; *Nature' Stories for Youngest Readers*, Anna C. Davis; *Nature Miracles*, Gray.

The limits of this article will not permit more than the briefest suggestions on methods in nature study, and the teacher is referred to the general texts already named as well as to the various able monographs published on the subject.

The first essential is to secure the co-operation of the home. If the teacher and the parents are working together, interest and progress will seldom flag.

The second essential is the wise selection of the material as already mentioned.

The third essential is the perfect familiarity of the teacher with his material.

The fourth essential is the sympathetic adjustment of the teacher to the child's consciousness. The fifth essential is the use of properly correlated literature and nature stories. Invaluable material will be found in several of the books already mentioned and also in the following: *Classic Stories for the Little Ones*, Mrs. McMurry; *Open Sesame* (prose and poetry for school-days), Ginn & Co., Pubs.; *Fairy and Folk Stories*, Scudder; *Andersen's Fairy Tales*, Stickney; *Tales of Troy*, De Garmo; *Stories from Plato*, Burt; *Heart of Oak Books*, D. C. Heath & Co., Pubs.; *In the Story Land*, Coolidge; *Child's Christ-Tales*, Hofer; *Hawthorne's Wonder-Book*, Houghton, Mifflin & Co., Pubs.; *Six Stories from the Arabian Nights*, Elliot; *Child Stories from the Masters*, Menefee; *Kingsley's Water Babies*, Stickney; *The Story Hour*, Kate Wiggin and Sarah Smith; *Apple Blossoms*, Scott, Forsman & Co., Pubs. See also the poets of every clime.

These stories serve not simply to entertain the child, but to enlarge his vision, to give his imagination free exercise, to intensify his interests, to cultivate his memory, to increase his vocabulary, to develop his powers of expression, to create a sympathy with life and to prepare him to appreciate the higher forms of literature. By their proper use, the nature world soon begins to glow with meaning and everything about the child speaks to him in a language which he can understand.

Nature study, as stated, furnishes the opportunity for a natural introduction of the elements of the formal studies as well as of the sciences. This fact enables the teacher to begin language and number teaching in the concrete and to utilize drawing, writing, music, and reading in the same way. Thus has arisen the plan of organizing the course of study in the grades known as correlation. For an elaborate discussion of the principles of correlation, see the *Transactions of the National Educational Association* for 1895, 1897, and 1899. For concrete illustrations of methods of correlating, see part II, *of Apple Blossoms*, published by Scott, Forsman & Co., and *Object Lessons and How to Teach Them*, Ricks. See also De Garmo's *Herbart and the Herbartians*, McMurry's *Elements of General Method*, Rein's *Outlines of Pedagogics*, and Ladd's *Philosophy of Mind*.

PHYSICAL EDUCATION AND MANUAL TRAINING.—The nervous system serves a double purpose in the physical organism of the child. It is the medium through which the external world excites sensations in consciousness and stimulates the intellectual faculties to action. This may be called its ideational function, for it is the occasion and source of ideas. It also serves to direct the movements of the various muscles and organs of the body. This is called its motor function. The development and co-ordination of these two great functions in such complemental relationship that they are always in free reciprocal action is to be provided for in every rational system of education. Nature study furnishes the means for the development of the ideational or intellectual activities of the child and also calls his motor activities into continuous action. The motor impulses antedate the birth of the child and during his waking hours for the first six or eight years of his life he is seldom willingly at rest. By experimentation he gradually differentiates the movements of the body as a whole, gaining that control and direction of the different organs which enable him to do things with ease and dexterity. The imitative impulse helps him to work out these problems of physical control in his earlier years, though the assistance of the members of the family aids him greatly at every step. Systematic calisthenic exercises may be introduced before the child enters school, but they should occupy a few minutes on each school day's programme after that. They should include exercises in breathing, in movements of the body as a whole and of the upper and lower extremities; they should develop the vital organs, grace in form and movement, strength, and subserviency of the body to the demands of the will. During all of these years great care should be given to the sleep, the food, the clothing, the personal habits, and the outdoor exercises and plays of the child, for in them all are found the factors that insure him health and vigor in after-life. For a detailed

treatment of this subject, see almost any work on hygiene, sanitation, and gymnastics. See particularly, Mason's *Manual of Gymnastic Exercises for Boys and Girls*, Anderson's *Methods of Teaching Gymnastics*, Blaikie's *Sound Bodies for Our Boys and Girls*, Keen's *American Health Primers*, Hunt's *Handbook of Light Gymnastics*, Morrison's *Ventilation and Warming of School Buildings*, Oswald's *Physical Education*, Safford's *Health and Strength Papers for Girls*, American Book Co.'s *Health for Little Folks*, Clarke's *The Building of the Brain*.

MANUAL TRAINING includes the school arts of writing, stick laying, drawing, wood working, clay modeling, wood carving, sewing, weaving, painting, etc. The handling of simple tools at home, such as the knife, the pencil, the pen, the needle, the scissors, the hammer, etc., anticipates the use of similar tools in the schoolroom and helps the child in the development of motor control as well as of manual skill; in fact, there is hardly anything that he does at his games or his work which does not serve a similar purpose. The course of study in every well-organized school gives a prominent place to some of the other school arts as well as to writing. Their place in the education of the child is being recognized more generally in all advanced systems of education than ever before.

Not only do they develop motor control and skill in doing things, but each act reacts upon the apperceptive activities, building up clearer notions and more positive definitions. So generally is this fact realized that *thinking and doing* have become indissolubly united in scientific pedagogical conceptions. Everybody has noticed how quickly a little effort at making a picture or a model of a thing helps him to discover its essential elements and fix them in his mind. Give a child a pair of scissors and set him to work at cutting out paper pictures and then at cutting out forms in imitation of leaves, triangles, squares, etc., and note how it helps him to clarify his notions of their shapes, sizes, margins, etc. Add to the above a little exercise in drawing them, then let him lay them out with splints, or sew them on card board; then model them in clay or soap; then let him paint them in water colors. Test him on his ability to describe or to recognize them and his growth will be the best argument for their use. What is true in the simple forms is even more true in the complex, thus on the purely intellectual side supporting the systematic arrangement of a variety of manual training exercises through the grades and into the high school.

The value of manual training on the art side is clearly enough seen in its ability to hasten the attainment of physical control and skill in mechanical execution. The average man or woman on entering some industrial occupation finds himself greatly handicapped by the lack of manual dexterity which should have been attained in childhood and youth, the only time when it can be attained with economy. Expert lace makers, jewelers, engravers, seamstresses, pianists, and violinists, decorators and designers, penmen, and weavers are not the only people who need nimble fingers and well-trained hands for their daily work. They are demanded in every walk in life, and all systems of education should provide for their development.

The expense in the elementary grades for the materials for each of the arts named is not much more than for the materials for writing and is not burdensome in the higher grades. For an inexpensive little book on *Manual Training in the Grades*, Abbott, from which illustrations are taken, address F. B. Abbott, publisher, Emporia, Kan. For more elaborate treatises on the whole subject, see Tadd's *New Method in Education*, Love's *Industrial Education*, and Goetz's *Hand and Eye Training*.

The following brief teacher's working outline in manual training for the *first grade*, exclusive of penmanship and drawing proper, will furnish a fair view of the work now being done in the best schools. Some phases are necessarily omitted on account of lack of space.

The materials needed are splints for stick laying, wire half circles, coated paper squares of the six elementary colors, a few sheets of common cardboard, a few pounds of well-ground clay, a pair of scissors, a few skeins of colored worsted, a few skeins of carpet yarn for weaving mats, a few sheets of perforated figure papers, a few pounds of raffia for weaving baskets, a paper of large needles, and a half-dozen weaving needles.

The object of stick laying is to teach spacing, design, arrangement, and orderliness. The paper folding gives practice in the simplest hand movements and in the use of the inch measurement. Tracing on the back of the colored papers over the creases gives practice in precision and accuracy. Working out figures with worsted in perforated paper helps to fix forms and co-ordinates eye pictures and finger movements. Clay modeling develops the idea of form and cultivates the sense of touch. The weaving serves many of these purposes and in the succeeding grades makes an excellent introduction to industrial occupations.

The course is arranged for two fifteen-minute periods per week; one in clay modeling and one in stick laying or paper folding.

The work is planned for twenty-three weeks; the numbers refer to the number of week, and the letter to the lesson.

1. (*a*) After conversation on the sphere, model the sphere, using fingers only.
(*b*) Measure side of four-inch red square.
2. (*a*) Model a spherical object.
(*b*) Lay red sticks to form a border illustrating repetition.
3. (*a*) Model a spherical object.
(*b*) Measure side of four-inch orange square. Fold, making a diameter. Teach diameter.

Measure distance from end of diameter to corner. Fold, forming a diameter at right angles to the first diameter. Trace on the back of paper over the creases, making a cross.

4. (*a*) Model a cube.

(*b*) Lay orange-colored sticks to illustrate repetition of twos.

5. (*a*) Model a cubical object.

(*b*) Fold a four-inch yellow square so as to form sixteen one-inch squares. Measure the squares. Trace on back of paper over the creases.

6. (*a*) Model a cubical object.

(*b*) Lay yellow sticks illustrating the repetition of threes.

7. (*a*) Model an isometric cylinder.

(*b*) Fold a green square to form a diagonal. Fold to form a diagonal at right angles to the first. Make six folds parallel to one of the diagonals, making equal spaces. Trace on the back of paper over the creases.

8. (*a*) Model an isometric cylindrical object.

(*b*) Lay green sticks to illustrate alternation.

9. (*a*) Model an isometric cylindrical object.

(*b*) Fold blue square same as in lesson 7(*b*) and in addition fold six creases parallel to the other diagonal, thus forming small squares. Trace over some of the creases to make a design, which shall be symmetrical.

10. (*a*) Model a cylindrical object with rounded ends.

(*b*) Lay blue sticks to illustrate oblique alternation.

11. (*a*) Model an object like cylinder.

(*b*) Fold a violet square as in lesson 9(*b*) and trace pin wheel design on creases.

12. (*a*) Model an object like cylinder.

(*b*) Lay violet sticks in design as a modification of 10(*b*).

13. (*a*) Model a sphere and bisect it with a string.

(*b*) Fold red square as 9(*b*) and trace symmetrical design on creases.

14. (*a*) Model a hemispherical object.

(*b*) Lay red sticks to form a Greek border.

15. (*a*) Model a hemispherical object.

(*b*) Fold a diameter in an orange square. Make six folds parallel to the first diameter. Form the same number of folds at right angles to the first set, thus making sixty-four quarter-inch squares. Draw a symmetrical design by tracing over the creases.

16. (*a*) Model a square prism and bisect across corners, forming a triangular prism.

(*b*) Lay orange sticks to illustrate alternation.

17. (*a*) Model a square prismatic object.

(*b*) Fold a diagonal in a yellow square and also seven creases parallel to it. Fold a set at right angles to the first. Draw symmetrical design on creases.

18. (*a*) Model a triangular prismatic object.

(*b*) Form a flag with three yellow sticks.

19. (*a*) Model a cylinder and bisect it.

(*b*) Draw the diameters and diagonals on the back of a blue square. Connect the end of the diameters in such a way as to form a square. Cut on the lines with scissors, making sixteen right-angled triangles.

20. (*a*) Model a hemi-cylindrical object.

(*b*) Make two borders using eight triangles of lesson 19(*b*) and blue sticks. These may be mounted.

21. (*a*) Model a hemi-cylindrical object.

(*b*) Draw on back of blue square two sets of parallel lines at right angles to each other, forming sixteen one-inch squares. Cut with scissors.

22. (*a*) Model cylinder with rounded ends. Bisect it.

(*b*) Arrange seven squares of lesson 21(*b*) in borders.

23. (*a*) Model a hemi-cylindrical object.

(*b*) Make a design of blue triangles — of lesson 19(*b*) — and blue squares — of lesson 21(*b*).

The knife and a few other simple tools are introduced as the work advances and habits of originality, of accuracy, precision, and speed are inculcated throughout the course. The views of specimens of work done in grades seven and eight show how the skill of the pupil develops through the years.

All of the work for the grades can be done on the ordinary school desks, though as a few heavier tools may be introduced in the seventh grade, benches will then be needed. In the high school, the work properly differentiates into certain specific lines each for the boys and the girls. Work benches, full sets of tools, lathes, scroll saws, etc., are needed for the heavier work for the former; sewing tables or kitchen furniture, depending upon the direction the instruction takes, are needed for the latter. Tables and tools in common can be used for clay modeling, bent iron work, wood carving, etc.

DRAWING is now universally taught in the best schools, and ought to be provided for in every grade. Its value in the development of motor control gives it great pedagogic importance, but its value as an aid in building up notions of form, relief, symmetry, movement, etc., is no less marked. Properly taught, its æsthetic value soon manifests itself even among little children. The practical value of drawing is seen in a great variety of industrial occupations, as well as in what are usually denominated the fine arts. Drawing serves to help to fix attention to many details in nature study, and adds surprising zest to children's work in getting the meaning of the printed page. The danger in teaching drawing is that the teacher may make it purely mechanical, lacking significance and life, meaning and movement. All scientific teaching involves both, and drawing is no exception. The initial movement in the first grade should be constructive, and the creative impulse of the child should be quickening and

enlarging at every step. Every process of analysis should end in reconstruction, and should stimulate invention.

In selecting a system of drawing books, the foregoing facts should not be forgotten. Much harm is frequently done by the failure to observe the law of sequence in organizing the work for the drawing classes. This law means more than the average teacher sees in it. It involves the organization of the exercises in such a way that the simpler in order develop skill for undertaking the next higher and more complex. All exercises for the development of motor control should follow the same law. It is the fundamental economic principle underlying the development of the mental activities as well.

The student and teacher will find any of the following systems, as outlined in their texts, well adapted to public school demands: Thompson's, Prang's, Cross', and White's. See also Morton's *Chalk Illustrations*.

PENMANSHIP is usually taught simply for the purpose of enabling the children to write a fairly legible hand. Its place as a means of contributing to motor development is generally overlooked. It is safe to say that few other subjects are taught with such meager satisfactory results as penmanship.

In the first place, there is little system in the methods in use; in the second place, too much time is spent on the writing lesson proper, each day; in the third place, the children are permitted to fall into careless habits in their writing in general, thus overcoming the good effects of class work.

Nearly all the modern texts on penmanship give necessary suggestions concerning methods of teaching the subject, which, if intelligently followed, should give excellent results. They are based upon the law of sequence, with its wider meaning, as explained in the paragraph on drawing, but they frequently exact more time per day than should be allotted.

Good penmanship is dependent upon perfect motor control. That is a growth of years. It cannot be forced, but it can be directed and hastened. The other school arts help to its attainment, and their correlation with penmanship is essential to rapid progress. If half the time now given to penmanship were given to them, there would be a gain to it, and they would be perfecting in like manner. The handwriting which the children would attain would prove permanent and would not deteriorate, as it usually does under the hot-house methods by which many writing teachers gain reputations.

Writing is but the record of muscular action. If the latter is accurate and graceful, so will the former be, hence the importance of the right kind of drill in the movement exercises. Such exercises should not only be on letters and parts of letters, but on words, as well. They should accompany the acquaintance with all new words, helping not only to fix their visualization, but also to fix their muscular pictures. This muscular spelling is vastly more important than oral spelling, for the latter is seldom used in the grades outside the regular spelling class, and almost never, afterward.

Exercises in writing words, logically selected, from the movement point of view, serve at once as exercises in spelling and penmanship. No other principle should dictate the classification of words in spelling lessons for the lower grades. Sufficient drill should be given on each new word to fix the muscular picture and the muscular movement accurately and permanently. When that is done, poor spelling will disappear and poor writing also.

Arbitrary slant and strictly vertical systems of penmanship cannot logically sustain themselves. Natural slant commends itself to the reason, and practically controls everywhere. Among the best up-to-date texts and courses are the Roudebush, the Zaner, the Jackson, the Natural Slant, and the Natural and Individual system by the Penmen Publishing Co., Port Deposit, Md.

LANGUAGE TEACHING.— Language has always occupied a high place in educational systems. It needs no argument to support its claims to recognition in a course of instruction for the youth in any time or clime. It is the first fine art which the child undertakes to learn; it is indeed the only fine art which all children cultivate to an appreciable extent. Being the vehicle of expression for every normal child and the only means for the rapid, diverse, and continuous exchange of ideas so necessary in every walk and stage of life, its value appeals alike to the artisan and the artist, the poet and the philosopher, the peasant and the man of affairs.

Beginning with the simple ejaculations accompanying the first glimmerings of consciousness, the child quickly and instinctively adopts the words he hears to designate the objects about him and to express the subjective states produced by his ever-enlarging experiences. With each new experience comes the demand for a new word. If the proper word be furnished at the proper time, it helps the child to differentiate the new object or the new experience from those preceding and to fix it more clearly and more permanently in his mind. Words greatly assist the child in the cleavage or differentiation of elements in his world of experiences, as well as in the construction of his notions and ideals from them. His mental growth is as much dependent upon the increase and the character of his vocabulary as upon the extension and variety of his experiences. Keenness and delicacy of perception are hardly attainable without the aid of words of equal delicacy of shades of meaning. This principle is even more evident of the higher activities and of the sentiments.

It has been well said that no nation lives morally higher than its language and that its

ideals and aspirations are no larger than its literature. It is equally as true of the individual. Mind culture and language culture are indissolubly associated throughout the whole home and school life of the child. The former is the object of all education, the latter is its necessary accompaniment. Clearly then, all other things being equal, the better the language the child hears and appropriates the more rapid and the more systematic will be his mental development. The superficial mind fails to observe the fact that the teacher usually must not only correct the language of a pupil, but his modes of thinking as well. When the latter is done, the former generally takes care of itself. This fundamental principle should dictate all language teaching whether in the home or in the schoolroom, whether in the primary grade or in the high school.

The most important thing in methodology is to help the child to the attainment of correct habits of perceiving and thinking; the next, to help him to the correct and forceful use of language in expressing his thoughts about the things he sees and hears and smells and tastes and feels.

A prerequisite to successful language teaching is clear thinking and accurate language on the part of the parent and teacher. The unconscious, ever-active imitative instinct of the child is generally more powerful than oft-repeated precept. "Nothing sinks so quietly and deeply into men's minds as example." This is probably more true of language than of any other subject of instruction. The art side of language is its use; the technical or scientific side is the knowledge of its structure and functions. In comparison with the other arts in general, it is unique in the fact that the study of the scientific side must await long years of use. While this is true of the mother tongue, it is not necessarily true of a foreign tongue, as it may be learned either by beginning with the grammar or by the conversational and constructive method. Though, so far as the child is concerned, he must enter upon the large use of language before knowing much of its science, that use should be scientifically and sympathetically directed by those intrusted with his education. The art of directing language culture presupposes a scientific knowledge of its genesis, its structure, and its function. It presupposes a knowledge of the nature and genesis of the mental activities as well.

As the child learns to read, his horizon gradually extends and words multiply almost as rapidly as ideas. It is important that the new words met in his reading should be clearly understood and used frequently enough in his conversation to insure them a permanent place in his vocabulary. If the process be properly conducted by the teacher, the transition to the printed page presents little difficulty to the child. As has been said, much depends upon the language which the child hears, but the necessity for pure diction and graceful style in the books he reads is no less vital. It cannot be too frequently repeated that while the child is appropriating words, he is also unconsciously appropriating forms of expression and of thought that soon become dominant and permanent elements in his intellectual life.

Language culture does not begin with the study of technical grammar, as too many people suppose. It begins with the child's first efforts to talk and is affected by everything he learns in the world about him and from the books he reads. It would be a serious error to interpret the foregoing as meaning that the instruction of the child should be so formal and stilted as to ignore his stage of development and to repress all originality and spontaneity. The child must not only be permitted to think and act as a child, but to speak as a child as well. Common sense is the most potent element in all successful teaching. The problem is to train the child to better child thinking and to better child language at every step of his progress and to do it in such a way as not to rob him of his great heritage,—*the privilege of being a child and of growing in a natural way to mankood.* The enrichment of the child's language at every stage of his growth will be accelerated more by the books of the high character named than by any text-books on grammar and rhetoric, however skillfully written. By the potent influence of their silent reading, they develop vigor and strength, precision and elegance, characteristics in every mind as essential as the knowledge of the subject-matter of which the books treat. The ideal books for children as well as for adults, however, are not of indifferent themes, but rather of those which touch the individual life on its universal side, which quicken and hold interest, which extend vision and develop life.

The choice of stories and of books for children should also be controlled by their environment and by their stage of development. They should correlate closely with the home life of the children and with the course for nature study in the lower grades. They should serve to stimulate observation and increase interest in everything with which the children come in contact. They should present pictures of other times and other lands somewhat similar to those of the little world in which the children live. Stories of primitive people, of Bible characters, of plants and animals, fairy tales, and simple fables always attract small children. At first they should be told or read to them and the children encouraged to reproduce them. As they are able to read for themselves, the repeated reproduction of the story in their own language should never be overlooked.

The following will illustrate the classes of stories which may be profitably used in the primary grades: Stevenson's *The Hay Loft;*

Kingsley's *The Lost Doll;* Andrews' *Seven Little Sisters* and *Ten Little Boys on the Road from Long Ago;* Longfellow's *The Builders;* Andersen's *The Fir Tree* and *Five Out of One Shell;* Field's *Rock-a-by-Lady* and *Little Boy Blue;* Wordsworth's *The Kitten and the Falling Leaves;* McDonald's *Little White Lily;* Sarah Wiltse's *The Diamond Dipper;* Lucy Larcom's *The Shower and the Flowers;* Susan Coolidge's *The Little Christmas Tree;* Amy Fisk's *Good Morning, How the Leaves Came Down, How The Chipmunk got Stripes on His Back, The Little Golden Rod, Seedlings on The Wing,* etc. The courses of supplementary reading specified for the grades in almost every first-class city school will be found useful in making selections for language work. Recognized classics only should be given to the children, because they alone lead them into the realms of universal interests. If wisely chosen, the series will beget a refined literary taste and an ever-increasing love for better literature. Statistics show that the child thus trained enters society with the least friction, and with clearer conceptions and higher moral courage takes up his part in the drama of life.

Language culture comes by practice in the intelligent use of words in conversation and in writing. When a child has something to say he ought to be encouraged, not simply permitted, to say it. He ought also to be given sufficient time to say it without that embarrassment which is the pernicious breeder of ill-chosen words, of incorrect pronunciation, of faulty construction, of unfinished sentences, and of what is far worse, if possible, of confused and indefinite thinking. He should not only be taught to use the truest word, but to use the truest sentence also, and to be unwilling to use any other. Tendencies to caprice, affectation, and carelessness should be wisely suppressed as they appear. While reproducing stories told or read to him, the child should use his own language, but he should be encouraged to use as many of the new words he has heard or seen as he can use intelligently. Discreetly, patiently, lovingly, parents and teachers should direct his early efforts in picture and word building. As the movement is continuously constructive, it offers unlimited opportunities to the growing child. With the extension of his knowledge into the larger fields of science and of the arts, as well as into the spheres of biography, history, literature, and national life in general, language continues to be the child's greatest passion, and loftier themes its perennial inspiration.

In his helpful book on *Teaching the Language-Arts,* B. A. Hinsdale enumerates the four agents that promote education in the vernacular language:—

1. Association, or social relations with our fellows, including listening to cultivated speech of a formal character, as sermons, orations, and the like.

2. The reading of good literature, both in and out of school.

3. Formal instruction in the language-arts, speech, reading, and composition.

4. The scientific study of language, and particularly of one's vernacular, or grammar.

"The first of these agents works in the life of the child from its birth, ceaselessly and powerfully. In no field of human activity or cultivation does imitation play a greater part than here. The second and third agents do not appear in the life of a majority of children until they go to school; and even in the minority, who have made some progress in those arts before that time, they work but feebly. Here, too, imitation asserts itself strongly. The fourth agent never becomes a practical factor in the education of a majority of children, because they do not study grammar; while in the cases of those who do study it, it is much less effective than the other three."

The construction of the first written sentence, be it ever so simple, is a great event in the life of the child. In it he enters upon the exercise of a new range of activities, a new form of expression. He now writes the word which he has only known how to speak, he sees the word which he has formerly heard. Other sense and motor centers become language centers also, and become connected with those already established. It is important that in taking up this new phase of the language-art, the child's mode of thinking should not be changed. His thoughts should run as easily, as naturally, as unaffectedly, in writing as in talking. It should be the same child that writes and talks. The deliberation incident to writing ought not to destroy spontaneity and separate the child from his natural self. It ought, however, to develop discrimination in the use of words and skill in the construction of sentences. Writing makes the exact man, and the influence of writing sentences and original descriptions and stories upon the oral language of the child is incalculable. If properly conducted, all exercises in both, mutually strengthen and perfect each other. The frequent and rapid going back and forth from one form of expression to the other, will help to preserve naturalness and develop facility in the use of both. The reason so many people find writing such a burden is that they were given little intelligent exercise in it in their childhood. This would not be cause for so much lamenting were it not that their oral language is usually correspondingly defective.

The mechanics of written language are no less important than those of oral language, which is treated elsewhere. Writing as a purely mechanical art is more properly denominated penmanship, and yet all expert teachers of that subject recognize the mental as well as the physical activities involved in the process. They are not unmindful of the fact that however desirable rapidity of movement, grace of form, or clearness of outline

may be in themselves, the end of it all is to give the child a ready and an effective means of expressing thought. The earliest exercises in penmanship should therefore be organized with reference to that end. When a pupil is ready to lay aside his regular practice in penmanship, the process should have become so fully a part of him that as he writes he need give no more attention to the mechanics of it than to the mechanics of his voice as he speaks. Writing lessons then should include an increasing amount of original composition with the advancing grades.

With the introduction of written language comes the introduction of exercises in capitalization, punctuation, indentation, and paragraphing. The capitalization of proper names may be introduced with the names of the days of the week, holidays, names of persons, etc., and as the child begins to understand what a proper name is; indeed its introduction will help to emphasize the last named idea and to stimulate the recognition of proper nouns as he meets them. As he is able to get a similar understanding of the other rules for capitalization they should be given with appropriate practice. In a similar way punctuation should be taught. It is an easy thing to teach the simpler uses of punctuation marks, but it is a great mistake to force their use upon the pupil before he is sufficiently familiar with the parts of a sentence, or of the discourse which they set off, to use them with reasonable intelligence. The ignorant or mechanical use of punctuation is worse than no use at all. It begets bad habits and lifelong confusion in actual practice. The world of letters got along for many centuries without them and the child need be in no undue haste about learning them. Successful punctuation in general composition is based upon a knowledge of sentential structure that comes only with mature scholarship.

Paragraphing in writing descriptions and narratives may be taught, at least in an approximate way, very early in the grades. It soon begins to serve as a means of differentiating the principal elements of a discourse and of magnifying the importance of unity in its construction as a whole,—two fundamental processes too little followed in composition.

Phonic analysis as an oral exercise is excellent drill for the primary and intermediate grades, though care should be taken not to use words with silent letters until the children can spell them both phonetically and alphabetically without confusion arising from their differences. The difficulties in pronunciation practically disappear in phonic analysis, for it is simply slow pronunciation. Spelling should never be overlooked in any written work, whether in dictation copying, or original composition. Generally speaking, children should see each new word in script before attempting to write it. It is that which they are to reproduce and not the printed nor the spoken word. The eye picture and the muscular picture in the writing process are to be so merged into each other that in consciousness they become practically one. Each new word should be written a sufficient number of times and in such varied relations as to fix so clearly and accurately the muscular movement involved that its future writing will be automatically done. Experience has shown that such a method of teaching spelling insures accuracy in spelling throughout the grades that no other method has produced. In practical life nobody spells many words orally. Why spend so much time in oral spelling as is frequently done in the public schools?

In language teaching, even in the lower grades, each child should be taught the meaning of the more common words both by definition and synonyms and by their use in sentences. At the same time the teacher may tactfully build up in the minds of the children notions of the different classes of words, the parts of speech, as they are called. They seem naturally to develop in the following order,—nouns, verbs, adjectives, adverbs, pronouns, conjunctions, prepositions, exclamations. By the close of the first year, the pupils should also be familiar with the time forms of the more common verbs, the number forms of nouns used, and the degrees of comparison of the more common adjectives and adverbs. The same exercises, a little more advanced, should be continued through the second year.

The third year will be well employed in teaching additional verb and noun forms, classes of adjectives, etc. The fourth year should give the pupil familiarity with a large range of the forms mentioned, with the more common homonyms and synonyms, with the use of capitals, periods, interrogation and exclamation points, the apostrophe in contractions and in the possessive case, and the comma in a series and in addressing letters.

Though in preceding grades the different kinds of sentences as well as the simple division of each should have been frequently noted and illustrated, they should receive more critical attention in the fifth grade. This year's language work should include the general classification of nouns, verbs, and adjectives, together with a free analysis of easy sentences and abundant drill on adjective and adverbial forms. Each year's work should re-enforce that of the preceding year by rapid illustrative reviews. As pupils enter the sixth grade, they should have exercises in great variety calling into use the different tense and voice forms of verbs, and the different classes of conjunctions and pronouns. They should also have ample drill in substituting alternately phrases and single words and in expressing ideas in a variety of ways, supporting preferences.

Children in the fifth and sixth grades find the origin and history of words a fascinating

subject. Exercises in making new words by means of prefixes and suffixes should be frequently given. Each story read, particularly if it be a story of classic lands, affords opportunity to illustrate the source and growth of words. For example, the stories of Hector and Tantalus give us hector, hectoring, tantalize, tantalizing, etc.

The foregoing shows briefly the method of developing the technical side of language and of preparing the child to enter upon the more formal study of grammar. For a more detailed outline for these and higher grades, the teacher and student are referred to the more elaborate state and city courses of study for the common schools and to the standard works on grammar. The formal study of rhetoric and literature belongs properly to the high school.

The bibliography of language teaching is now so rich and helpful that there is little excuse for faulty work in this subject. The following are among the best books: *Teaching the Language-Arts*, B. A. Hinsdale; *Talks on Writing English*, Arlo Bates; *The Forms of Discourse*, Cairns; *The Science of Discourse*, Tompkins; *Part Third of the Report of the Committee of Fifteen*, W. T. Harris; *Essentials of English Grammar for the Use of Schools*, Whitney; *Life and Growth of Language*, Whitney; *The Story of the Alphabet*, Clodd; *Everyday English*, White; *On the Study of Words*, Trench; *Synonyms*, Crabb.

A. R. Taylor.

Methods in Reading.—The teaching of reading in the grades should have in view four objects, — rapid recognition of sentences as symbols of thought, concentration of attention upon the thought read; the development of a discriminating judgment, and the power of *expression*. The last named includes extemporaneous speech and interpretative reading.

The reading lesson should be the introduction to the world of letters. It should cultivate literary taste. It should mould thought and character.

Good literature, like good music, must be *heard* often to be thoroughly appreciated. The ear as well as the mind should be trained. The children of a few parents have this opportunity in their homes; but the children of the many have only what the public schools can offer them. It is very essential, then, that every teacher of the grades should have a cultivated voice and literary tastes. A beautiful reader can lead children to love the classics.

Reading to the children should be a part of the weekly programme throughout the first eight grades of the public schools. Once a week, the teachers should read aloud to the children, and conversation upon the subject-matter read, or a reproduction of it, should follow.

The classics read to and by each grade should be carefully selected and graded. This choice should take into account the awakening of a love of nature, the cultivation of imagination, the teaching of truth and right, patriotism, and the formation of true literary taste. This reading should help to make character, awaken thought, and teach the simple duties of daily life. Haphazard reading to children, or by children, does not accomplish the same result. There should be a definite plan in the presentation of all of this work. The children should be introduced gradually to fiction, poetry, natural history, biography, history, and travel.

The class or department library meets a need at this point. When each class-room has its own carefully selected and graded library, it places within the reach of children a great educational influence. It gives children the opportunity to handle books and to know books. The teacher here has an opportunity to guide and interest children in reading literature.

To cultivate concentration of mind, and to develop command of language and natural conversational delivery, there should be frequent oral reproductions by the children of paragraphs read by them. This tests their grasp of the thought.

The study of reading should lead to and overlap the study of language. The reader, in following and grasping the consecutive thoughts of an author, follows the mental processes of the author, and, step by step, thinks his thoughts after him. Continued careful and thoughtful reading trains the mind to careful and logical thinking. Reading that is *thinking* awakens the creative impulse, and the effort to express the soul within through interpretative reading or authorship. Healthy growth of mind must find expression in some way. What more stimulating means to the boy or girl than the interpretation of the noblest thoughts of the great masters of literature!

We must bear in mind that the study of reading in the grades is a literary study, and that every child should not only be led to *understand* the thought of literature, but to interpret it. Reading is not simply the saying of words. It is putting into the words read the reader's thought as *he* thinks the words. He colors with his own thought and feeling what he reads. He interprets the soul of literature. Beautiful reading is a rare accomplishment because few have learned the secret of interpretation. The secret is oft repeated study to understand every possible shade of thought, coupled with daily oral practice to express every shade of thought.

Sometimes the mechanics of reading are dwelt upon at the expense of the thought; sometimes the thought interpretation is magnified at the expense of the mechanical part of reading. Both are essential. But in all the teaching of interpretative reading, great care should be exercised to lead the readers to *think the thought* as they read aloud, and not weaken the expression of the thought by

thinking of the technical or mechanical form of the reading.

Many methods of teaching primary reading have come and gone. Still the fact remains that in some places beautiful reading always has been, and always will be, found. More depends upon the teacher than upon the method. Thought should precede expression. Let the method here suggested be called a *thought* method, and its chief object *expression*.

First Year.— It is best that only one small group of children should gather at a time about the teacher for recitation, while the other groups are engaged in busy work at their seats.

The first five or more "reading" lessons should be purely *conversation* between teacher and pupils. The object of this is to prepare the way for conversational tones in reading and speaking.

The next step should be to draw forth from one of the children a complete sentence, and immediately write it in *script* on the blackboard, at the same time telling him that it is his sentence. The child should be asked to read his sentence. The teacher should see to it that the little reader never loses the natural inflections and modulations of the voice.

This same sentence should be developed with, and read by, each child as before. Then the teacher should erase all but one sentence. This she should cover, and then ask the children to think how it looked. This is an important step, for it is the first lesson in how to study,— concentrated attention.

The sentence work should be continued about fifteen weeks, when the study of words should begin. By the eighteenth week the study of words should be followed by the study of the alphabet, and this in turn by a few of the elementary sounds.

At the close of the twentieth week, the transition from script to print should be made. It would aid very materially in the success of teaching reading at this stage, if the teacher could have several sets of first readers in which the script sentences are accompanied by corresponding printed sentences just below. The wise teacher will have developed in script the sentences that the children will find later in the first half of the first readers they will use for sight reading.

New words of each new lesson should be written on the blackboard, and pronounced by the teacher. After the children have learned the diacritical marking and elementary sounds, they should determine the pronunciation from the word as it is marked diacritically by the teacher.

Children should be taught to *think* sentences as they read them, and the teacher should correct unnaturalness of expression or unpleasantness of voice.

During the last twenty weeks of the first year, the children should read through at sight all of the lessons of the first half of six or eight first readers. It is well to rotate the sets of books, reading the first lesson in the first set, the first lesson in the second set, the first lesson in the third set, and so on. In this way the reading material is more gradually graded.

As soon as children are able to read the simpler classics, these should be used for supplementary reading.

Some power of interpretation is developed by *sight* reading; but real opportunity for interpretation drill comes in the recitation of memory gems. By skillful questioning, description, and illustrative reading, the teacher should lead the children to understand and feel what they recite.

The following list of memory gems is here offered as a suggestion.

Memory gems for first and second grades:—
For the spring,
The Dandelion, by Proctor.
The Cuckoo, by Wordsworth.
For summer,
Seven Times One, by Jean Ingelow.
The Brown Thrush, by Lucy Larcom.
For fall,
Down to Sleep, by H. H. Jackson.
Little Boy Blue, by Eugene Field.
For winter,
Story of The Advent, Luke ii., 8 to 16.
The Snowflake, by H. W. Longfellow.

Second Year.— In the second year reading work, the study of the elementary sounds should be continued, and the children should be able to give, and to recognize, and to mark diacritically, all of these sounds at the close of the second year.

There should still be development of new words about to be read, sight reading, rapid thought analysis during sight reading, and a continuation of conversational reading. Classics should be read to the children and be reproduced by them. Memory gems should be studied and recited for expression of thought and feeling in voice and face.

While the children are reading through, at sight, the second half of the first readers, and the first half of the second readers, and a few second-year classics, they are gaining mechanical skill in reading words as thought symbols, and groups of words as thoughts. Children should be taught to utter words in groups, or to phrase as soon as long sentences are used.

Third, Fourth, and Fifth Years. — A similar plan should be followed for the reading lessons of these grades. In addition, attention should now be given to prepared lessons for interpretative reading. Each lesson for interpretation should be assigned, new words developed, allusions to history or literature explained, and attention called to points children should ascertain for themselves. The first recitation of the prepared lesson, if the selection is difficult, should be confined to the study of the text. The chil-

dren should be made enthusiastic in their effort to bring out the thought, and make it attractive to those who listen. During these years, the children should practice reading aloud at least a half hour daily. When children do not express the thought, they should again be helped to see it by explanation, or illustration, or description, or question. The teacher's voice, its sympathetic shading, and her interested manner, may be made an incentive to young readers. Judicious words of approval should be used to encourage each effort, however stumbling it may be, when the reader is beginning.

The dramatic element is especially attractive to children, and helps to hold their interest and to overcome self-consciousness. It adds to the zest of the reading lesson in those grades to introduce an occasional dialogue for supplementary reading. An arrangement of dialogues from the works of such writers as Kate Douglas Wiggin, Frances Hodgson Burnett, Sophie May, Nathaniel Hawthorne, and others, published by Messrs. Hinds and Noble, under the title of *New Dialogues and Plays*, would be exceedingly entertaining and profitable for these and the higher grades.

The memory gems should be wisely chosen; they should be selected with reference to beauty of thought and diction, and also for the lessons of patriotism, truth, gentleness, etc., that they will teach.

As no interpretation of literature can be beautiful without a cultivated voice, it follows that vocal exercises should now accompany the reading lessons. These should be given daily, and should lead to clear, musical tones, to distinct articulation, and to the expression of thought and feeling in the voice.

Sixth, Seventh, and Eighth Years.— In addition to sight reading, classics, memory gems, etc., of the first five grades, there should now be frequent drill in breathing exercises, vocal exercises, pronunciation, enunciation of difficult phrases, emphasis, spacing of words, and movement. This work should be carefully planned for each of the three grades.

There should be at least three prepared lessons per week in interpretative reading. This should include text study,—a study of the meaning and force of words, and at least an hour's oral practice daily. If the selections in the text-book used have not sufficient vitality and interest, the teacher should dictate something to the pupils that has.

During these three years the children should study, for the English and for the interpretation of the thought, several of the American classics. The study of the thought alone is not sufficient, for it is not until pupils repeatedly endeavor to interpret passages of literature that they see and feel the full beauty of thought. Getting at the soul of literature, requires close and careful study of the thought on the part of the pupil, and sympathetic and judicious leadership on the part of the teacher.

During the eighth year in school more attention should be given to the speaking voice. Children should be taught the importance of correct breathing and its relation to the voice and to health. They should be taught how to place the tone well forward so that the voice will become resonant and musical, how to support the tone so that it shall have a firm quality, and so on. A few simple exercises should be given daily, leading gradually to the resonant, firm, and well-modulated voice of the cultivated man or woman. The importance of the voice training in connection with interpretative reading can hardly be overestimated. It is a spiritual force in education, and may be made so by the true teacher.

It may sometimes be of great advantage to study one great classic throughout a year. Take "Julius Cæsar," for example, and make that the textbook for sight reading, paraphrasing, for interpretative reading, for memory gems, and for vocal exercises. The memorizing of a great literary work, the close companionship with its characters and their thoughts for many months lead to a deeper insight into the soul of literature. This is *knowing literature*, not knowing about literature.

With each effort to make vocal his own conception of the lines, the student not only gains in the power of interpretation but he gains in the power of self-expression. C. M.

Methods in Geography.— Geography is the study of the earth's surface as the home of man. It differs from physiography in this: that while physiography deals with the question, how the earth came to be what it is, geography devotes itself to the effects of surface features upon mankind. The chief characteristic of the study is the relativity of man to his home, and not, as often assumed, a mere description of the earth's surface. Neither is the study of man alone any nearer approach to geography, but if any thing, a wider departure. Not the home alone, nor man himself, but man in his home, — that is the function of geography proper. To Karl Ritter, the first great teacher of the subject, is due the credit of the present view of the true field of geography. The best-adapted definition of Ritter's somewhat involved one, is possibly that of E. C. K. Gonner, of University college, Liverpool: *Geography may be described as the meaning to man of the earth and its features as they are.*

Such being the scope of the subject, it is possible for its study to begin in the first grade. The outline of a course of study in geography, given by F. W. Parker in his treatise on, *How to Study Geography*, is a superior one for all the grades, but that part of it which deals with the work of the first grade deserves distinctive mention. It

aims to help the child to find himself, to realize his environment and the relations, so far as he may be capable of observing them, that exist between himself and his home. So taught, it must follow that the child will recognize the meaning which relates the Eskimo to the tundra, the Tibetan to the plateau, the Kirghiz to the steppe, the Negrito to the forest, and the Troglodyte to his cave. Studied in the way indicated, strange people will not necessarily seem "freaks," nor other parts of the earth "out of his world." His larger knowledge must increase his humanity, and enhance his appreciation of the earth.

John Burroughs somewhere states that the end of education is to know the earth as a whole. It is no easy task at best. Columbus cleverly set the egg on end. The teacher simply cuts the ball in twain, and what seemed a physical impossibility, both sides of a ball are shown at once in the hemispheres. It is a hard task to grasp the relations existing between the surface units of this earth, 200,000,000 square miles of land and water, and the peoples of the earth, 1,500,000,000 in all. But it is an end worth all the effort that the problems imply. The culture value of a knowledge of the meaning of the earth's features to man is enough in itself to justify the claims made for geography by the teachers of the subject, overshadowing even the so-called use value of its facts.

The sense of sight is involved in geography more than any other one of the senses. The first work done should be based upon observation almost exclusively. When the things present to sight have been pictured, then the imagination must be called into exercise to develop the power of visualization, so that absent objects, whether seen before, or only described, may be readily visualized. To this end, objects, models, sand pans, pictures, and descriptions should be used in abundance. The stereopticon can frequently be used to advantage. Closely following in the advancing grades, must come the reading of maps, through which the skillful teacher may bring out much correlative and associative material. The sand table, which has been in use through the preceding grades may still be used to advantage, although the teacher should ever guard against the evils of exaggeration. Chalk modeling is perhaps the best means for graphic work in treating small areas.

As aids to geography teaching, a magnet, a compass, a dipping needle, a dial, a rain-gauge, a weather vane, a thermometer, a barometer, stencils, colored crayon, and small papier-mache globes will be found useful from the first. For advanced work there are many more complex pieces of apparatus suitable for demonstrating the laws of the physical universe, as well as of the forces producing chemical changes. If there is one thing needing emphasis in geography teaching, it is more laboratory work, more of the fields, more of the world about us and less of books. Geography logically begins with nature study, and develops through an extension of community environment to continental and world environment. It includes such a variety of surface, meteorological, climatic, biological, industrial, commercial, social, and political problems that local material need never be wanting; neither need concrete illustrations in great variety be lacking as the vision of the pupil is extending beyond his own neighborhood.

The making of models representing groups of people in typical settings of the regions which they inhabit will always prove interesting and instructive. A lesson in modeling groups to represent *The Seven Little Sisters* will not fail to satisfy the teacher of the advantage of such work.

The sources of information on this subject other than the regular texts are authenticated cuttings from newspapers, articles in magazines, bits of personal experiences and books of travel, of which there are now hundreds written in a most delightful manner. Such books as Nansen's *Farthest North*, Abruzzi's *The Ascent of Mt. St. Elias*, Hedin's *The Roof of the World*, and Borchgrevink's *Story of the Farthest South*, are of especial worth, bringing to the class reliable matter rendered doubly interesting by the intensely personal flavor of the recital. It is to be doubted whether there is a better set of books in any single series for geographical work than Reclus' *The Earth and Its Inhabitants*. The voluminous publications by our state and national government are also of great value.

For the teacher *The Statesman's Year Book*, Redway's *The New Basis of Geography*, *The International Geography*, edited by H. R. Mill, and Adams' *Commercial Geography*, are almost indispensable. It should go without saying, of course, that every class room for the scientific teaching of geography should be supplied with a globe, up-to-date maps, atlases, gazetteers, and current geographical magazines. D. A. E.

METHODS IN HISTORY.—History is that branch of knowledge which treats of the life of peoples. That life expresses itself in activities centered about the home and its environments, and we say we are confronted by social problems. All of this is one phase of history. That life expresses itself in the evolution of school systems, and we say we are dealing with educational problems. It is but another phase of history. Again, that life expresses itself in the development of the natural resources of the country, in the intercourse of the nations, and in the adjustment of man's relations to his brother, in the determination of man's relations to his Maker, and we say we are considering human activities as manifested along an economic, political, or religious line. Each in turn is but another phase of history. True history takes account of thoughts and feelings and motives, of influences and tendencies and

environment. An event is but a landmark. It is but the register or index of this life-movement. True history not only deals with the past, but with the living present. Furthermore, it reaches out into the future just as truly as do educational or governmental policies, building on the past, plan for future contingencies. The teacher or student of history, who confines himself to the event alone, fails even to reach the entrance to this field, broad as the world, and varied in its display as humanity itself.

The sources of history are multitudinous. Second-hand material is in abundance in texts, in extended works on historical subjects, in treatises on intellectual and social development, in books on geography, political economy, commercial law, government, and kindred subjects. Original material is available in public and private documents, messages, reports, speeches, addresses, proclamations, debates, national statutes, state enactments, city ordinances, newspaper accounts of events, newspaper caricatures, autobiographies, personal memoirs, individual diaries, camp notes, tourists' journals, photographs, monuments, historic places, relics, curios, private historic collections, state historical museums, individuals living, who have participated in great movements, or who have created, fostered, or furthered new ideas, etc.

The practical advantages to be derived from the study of history are these:—It develops the social instinct; it presents the true status of the business life; it records man's successes and failures in the field of government, and to young and old, in unmistakable terms, it points out the true standard of noble living. By the study of the social instinct, laws of society are discerned and amplified. Imitation is natural to all. Since history records no achievements of hermits, no benefits to the human race from anchorites, children and adults readily catch the meaning of associated effort. By the study of history are seen the exact effects of organized business enterprises, pursuing well-defined policies, and as affected by exterior influences. Often this study furnishes the only opportunity for the boy or girl to see the relation of cause and effect in business before becoming an actual participant in the business world. Our form of government makes it particularly desirable that every member of the body politic should be conversant with the history of his own nation at least. The statesmen of to-morrow are the students of to-day. A principle of government which yesterday proved inadequate to our advanced stage of civilization should be given no consideration whatever in the future. From what source can the future promoter of national prosperity get wisdom prior to his entrance upon the experimental stage better than from a study of the successes and failures of his predecessors? The ethical value of historical study is found in the careful analysis of the motives prompting action. In every case, such an analysis forces an historical judgment both as to effect—loss or gain, success or failure, static or dynamic—and as to means used—deceit or honesty, right or wrong, partisan or statesmanlike. With each historical judgment, the student's ethical ideals take more definite shape.

The method of historical presentation has been thoroughly revolutionized in the last few years, as has the conception of what constitutes historical material. It is now handled as a thing of life, full of personalities, having an immediate connection with *here*, and *now*, and *me*. It has something for the kindergartner, as well as for the bank president, college professor, or diplomat. Interest may be aroused at once in young and old by a study of local history and traditions. What New Englander or what dweller upon the historic Hudson or the Ohio, or what inhabitant of that once far-famed great American desert, or what citizen of that wonderful country beyond the Rockies, but must feel his heart swell with pride as he listens to the stories of adventure, of sacrifice, of marvelous discoveries, and of wonderful achievements, which once occurred in the locality about his home. How natural the transition from such a starting-point to the investigation of institutional life itself. A boy lives near the old Kansas home of John Brown. He learns the story of that man's life in Kansas. He is naturally led to the study of the institution of slavery. This involves the study of how slavery was introduced; what conditions of soil and climate gave it territorial location; what industries best utilized it; what peoples found it to their interest to maintain it; what conditions were necessary to perpetuate it; how it came to be a moral question; from what sources and why arose the first antagonism to it; the development of this opposition; constitutional questions involved; great men and women connected with the struggle; the great civil strife; resulting conditions; present grave questions pending solution. With the boy's interest in John Brown's old home as a basis, he may be led to the consideration of the gravest questions, economic, social, governmental, and ethical, with which our nation has ever been confronted. It matters not whether the boy's or girl's interest is first aroused by Plymouth Rock, Wall Street, Old Vincennes, Sam Houston, or Sutter's Mill, the same general method of inquiry will naturally follow. It will embrace the beginnings of things, causes, motives, external conditions, development, leading events, failures, successes, present condition.

In directing such investigation, the teacher may find it to his advantage to assign the topics for the day's work in some good text, but there should be free consultation of other authorities. Every class room should be supplied with reference books, maps, charts,

pictures, etc., illustrative of historical topics. If the maps and charts needed are too expensive to be purchased, they can be easily made. Several yards of white drilling, and a box of Dove drawing crayons, or a similar amount of flexible blackboard and a bottle of white ink, or some heavy manila paper and oil paints, *plus* an energetic teacher, will soon put at the pupil's disposal an abundance of exceedingly valuable and helpful maps and outlines. An active boy, a sharp jackknife, and a cigar-box may furnish some article illustrative of "Ye olden time," and fulfill more than one educational maxim. In this day of stencils, penny pictures, and newspapers, a teacher with a pair of scissors and the passe-partout picture binding, will easily provide the history classes with an abundance of illustrative material. The colored charts which appear in this volume will be found, it is believed, exceedingly helpful in fixing in the mind the landmarks of history, in their sequence and contemporary relations.

The fairy tale and the mythical story, which have so long served to quicken the imagination and introduce the child to literature, are now being partly displaced by the stories of real life which give him a taste for the study of history. Biography in the story form, well selected, logically related, and entertainingly presented, is the proper historical work for the lower grades. All periods of history should be drawn upon, particularly those periods which furnish characters living simple lives, making great sacrifices, performing deeds of heroism, and coming somewhat within the range of the child's own experiences and understanding. Certain ethical ideals, positive and negative, should control the selection of historical personages for the children, and their presentation should stimulate criticism, and the development of ethical as well as historical judgment. Tact and enthusiasm will give these stories even more interest for the children than the fairy tale, for they love to learn that the story is true. It is a mistake to ignore what may appear to us to be commonplace elements in biography, for they are often the very means by which the children's interest and understanding are aroused, and it is out of them that they build the fabric of history, even as from them the more complex life of succeeding civilizations has arisen. In the higher grades, this biographical study should gradually assume a more exhaustive and systematic form. As the child may be able to take an interest in institutional history, the origin and growth of the various social, industrial, commercial, educational, and civil institutions, particularly of those more nearly touching his every-day life, should be introduced. Biography gradually begins to get signification in institutions, and as early as in the seventh grade the two should merge into a connected historical study, completing a general view of the development of one's own country in the eighth grade. American history should not be considered as completed, however, in the eighth grade. It should be the crowning historical work of the senior year in the high school. Ancient, mediæval, and most of modern history, chronologically and logically precedes the larger view of American history, which should be given to every American youth.

A few suggestions may well be kept in mind: Especially in historical presentation, never tell the pupil what he can work or think out for himself. This applies equally well to reviews, daily recitations, or speculative work with facts in hand.

Use dates simply as pegs upon which to arrange facts of historical knowledge. Treat events as merely the vehicles which bear the precious freight of life, and thought, and character of the people. The event is the shell, the real thing is *in* it. The event is but the form, the content or contained idea is what the pupil should obtain and with which he should deal. Let the event always precede the date. Pupils should be incited, even forced, to think. The teacher should be a continuous question mark of why and what for. After the what and when should always follow the pupil's opinion as to why it is thus and so. With such a method as this, the pupil will find no profit in the old-time method of memorizing his history lessons and repeating them like a parrot or a phonograph, as the teacher may turn the crank.

Make use of the dramatic element in history. It serves the double purpose of maintaining interest and of making things seem more real, two very certain essentials in this subject.

Teachers should be sure to be far in advance of their brightest pupil. They should always be able to add to the sum total of the class recitation. Each day every pupil should carry away some new thought upon which to feed. The student who knows something well, thinks independently, and possesses ability to express himself clearly and forcibly, has attained that equipment which will enable him to serve well his day and generation.

The following books on matter and on methods of teaching history will make a royal little library for the teacher's study or the schoolroom:—

Methods:

Mace — *Method in History.*

Hinsdale — *How to Study and Teach History.*

Hall — *Method of Teaching and Studying History.*

McMurry — *Special Method in Literature and History.*

Channing and Hart — *Guide to American History.*

M. A. W.

METHODS IN ARITHMETIC. — Mathematics is the science of quantity.

Quantity is any thing that is capable of increase or decrease, as a line, surface, volume, weight.

Quantity is of two kinds — magnitude and multitude. Quantity of magnitude is quantity in an undivided form, as water, grain, earth, hence man has invented various units with which to measure it. This gives rise to a system of weights and measures and furnishes a subject for mathematical operation usually called denominate numbers. Quantity of multitude is quantity in a divided form, as trees, rivers, apples, houses, the units of which may be natural or artificial.

Arithmetic is a branch of mathematics. It is one of the oldest and purest products of the human mind. Arithmetical ideas are among the first that enter the human mind and they are so interwoven with all forms of human thought and action, that the history of arithmetic and its development cannot be separated from the development of the human race.

Arithmetic is the science of numbers and the art of computation. Science is knowledge classified in accordance with some fundamental principle; hence the science of numbers consists of the principles and relations of numbers. Computation is the application of the principles of arithmetic to individual examples.

All numerical ideas begin with the unit, hence the unit is the basis of the science of numbers. All numbers originate with the unit. The unit may be multiplied or divided. If multiplied the result is an integer, — if divided, the result is a fraction. Therefore numbers are of two kinds, integers and fractions. The process that originates integers is synthesis and the process that originates fractions is analysis. All other operations are modi-

fications or variations of synthesis and analysis — the two fundamental processes — and are mechanical. If numbers are examined in order to determine whether to add, subtract, multiply, or divide, the process is called comparison and is a thought process.

The operations of synthesis are addition and multiplication. The operations of analysis are subtraction and division. The operations of comparison are ratio, proportion, progression, percentage, and properties of numbers.

Notation and numeration, addition, subtraction, multiplication, and division are called the *fundamental rules of arithmetic.*

Notation and Numeration is the art of writing and reading numbers. The young pupil must learn small numbers by handling objects. He must learn the number, the name of the number, and the character which represents it. Sticks, grains of corn, marbles, or any other articles may be used but sticks of wood are the most convenient. The teacher may present a number of sticks and ask the pupil for the number and the character which represents it, or the teacher may call for a certain number and the pupil will present the sticks corresponding to it. After the pupil has learned the numbers to 10, bundles of sticks of ten each may be formed. The numbers from 11 to 99 may then be learned as 1 ten and 1 stick, 1 ten and 2 sticks, 2 tens and 7 sticks and so on. Bundles of 100, bundles of 10, and loose sticks may be used to represent numbers from 100 to 999. After a reasonable time the pupil must learn to image numbers. The only way to learn to image numbers is to image them.

After a certain stage of advancement in mathematical knowledge it became necessary to adopt a system of writing numbers. Any number might have been chosen as a basis of a system of numbers. Since man has 5 fingers on one hand, 10 on both hands, and 20 fingers and toes, it was natural that these numbers should be chosen as a basis of a system of notation, and in various parts of the world all of these numbers have been so used. During the lapse of ages it has been a question of the survival of the fittest, and at the present time 10 is almost universally used.

After the pupil has learned the numbers to 999 by the use of objects, he must learn to represent large numbers by the decimal notation.

By the common method the number to be read is separated into periods of three figures each, 693687946875 is read 693 billion, 687 million, 946 thousand, 875. This method is the only method in use at the present time.

To write numbers: write a period; write a comma in place of the name of the period; fill vacant periods with ciphers. To read numbers: begin at the right and separate into periods; name the periods in the same order; begin at the left and read the periods.

Addition, the fundamental synthetic process in arithmetic, is the process of finding the sum of two or more numbers. The sum of two or more numbers is a single number expressing as many units, fractional or integral, as there are units in all the numbers added. Numbers of the same denomination only can be added. The sum is of the same denomination as the numbers added. The sum is the same in whatever order the numbers are added.

There seems to be two distinct stages in the study of addition. The primary stage is the period when the addition table is built up by counting process. In this stage small numbers are used, with no reference to a system of notation by which to write large numbers. The work is purely mental and might properly be called *pure* arithmetic.

In the first stage, by counting objects the pupil obtains the primary sums of arithmetic, or the addition table.

For example, if he wishes to find the sum of 5 sticks and 4 sticks he begins with 5 sticks adds by ones, or counts, until he uses 4 more sticks. He finds the result to be 9 sticks and henceforth he must remember that $5 + 4 = 9$. The primary sums can hardly be said to be determined by the aid of reason but are intuitive rather. Why does $3 + 3 = 6$, $3 + 3 = 4 + 2$, or $5 + 1$? There is no reason for it. The learner looks at $3 + 3$ and sees that the sum is 6, $4 + 2$, and $5 + 1$.

After the pupil has learned the 45 combinations or primary sums by the use of objects, he proceeds to add larger numbers and continues the use of objects. For example let it be required to add 27 and 36. The numbers are written on the board

$$\begin{array}{r} 27 \\ \underline{36} \end{array}$$

and 2 bundles, of 10 each, with 7 sticks are laid upon the table and below them 3 bundles and 6 sticks. The pupil proceeds to unite the 7 sticks and 6 sticks, and finds that he can make one bundle of 10 and have 3 sticks left. He then puts the bundles of 10 together and finds that he has 6 bundles of 10 and 3 sticks. He expresses the result as 63. This process may be continued into hundreds, but only so long as it may be necessary to give the pupil a clear understanding of the process. He must then *image* his magnitudes.

In the second stage, the learner must be taught to perform addition of numbers expressed in the Arabic notation. When he learned the primary sums he learned to express them with figures and now it is an easy transition to the expression of larger numbers.

For convenience, write the numbers to be added so that units of the same order may stand in column. Add each column separately, beginning with units in order that sums may be reduced to higher orders.

Let it be required to add 628, 867, 943, and 785.

The work will appear as follows: —

628
867
943
785
3,223

Explanation.— The sum of the units is 23 units, or, 2 tens and 3 units. Write the units in units' column and add the tens to the tens' column. The sum of the tens is 22 tens or 2 hundreds and 2 tens. Write the tens in the tens' column and add the hundreds to the hundreds' column. The sum of the hundreds is 32 hundreds, or 3 thousands and 2 hundreds. Write the hundreds in hundreds' column and the thousands in the thousands' column. Therefore the sum of the numbers is 3,223.

Form of Analysis.— A pencil costs 5c, a slate 10c, and a book 8c. What is the cost of all?

Analysis: All will cost the sum of 5c, 10c, and 8c, or 23c.

Subtraction is the fundamental analytic process of mathematics. Every synthesis must have, or at least implies, a corresponding analysis, hence subtraction may be said to be the process of finding the difference between two numbers. The difference between two numbers is the number which must be added to the smaller that the result may equal the larger. The question: "What is the difference between 9 and 5," is equivalent to the question: "What must be added to 5 that the result may be 9?" No subtraction table as such should be taught, but the learner should find results by the addition table. When he learns that 5+4=9, he learns that 9–5=4, and 9–4=5. The number to be diminished is the minuend. The number to be subtracted is the subtrahend. The result is the difference, or remainder.

As in addition, subtraction may have two stages. The first stage consists of finding the primary differences, which is *pure* arithmetic independent of any system of notation.

The use of sticks should be continued in subtraction. Let it be required to find the difference between 63 and 27. Write the numbers

63
27

Put down 6 bundles of 10 and 3 sticks and ask the pupil to take away 2 bundles and 7 sticks. He sees that he must break one bundle, that he then has 13 sticks, and that he now can take away 2 bundles and 7 sticks, thus leaving 3 bundles and 6 sticks, which he expresses as 36.

The second stage is the process of finding the difference between two numbers when the numbers are expressed by the decimal notation. Principles to be emphasized: 1. Only numbers of the same denomination can be subtracted. 2. The remainder must be of the same denomination as the minuend and subtrahend. 3. Equal numbers may be added to or subtracted from both minuend and subtrahend without altering the value of the remainder. 4. The minuend equals the sum of remainder and subtrahend and the subtrahend equals the difference between minuend and remainder.

Rule.— Write the subtrahend under the minuend, placing units under units, tens under tens, and so on. Subtract each figure of the subtrahend from the figure directly over it and place the remainder beneath. If the lower figure exceeds the upper figure, add to the upper figure one of its units of the next higher order. Subtract, and proceed as before.

Example.— From 67321 subtract 39586.

The work will appear as follows: —

67321
39586
27735

Explanation.— 6 units cannot be subtracted from 1 unit. 1 of the tens added to the 1 unit = 11 units. 6 units from 11 units leaves 5 units. 8 tens cannot be subtracted from 1 ten. 1 of the hundreds added to the 1 ten = 11 tens. 8 tens from 11 tens leaves 3 tens, and so on.

Form of Analysis.— John had 13 marbles and lost 6 of them. How many had he left?

Analysis: He had left the difference between 13 marbles and 6 marbles, or 7 marbles.

Multiplication is a short process of making several additions of the same number, hence it is a special form of addition. The multiplicand is the number to be added. The multiplier is the number which shows how many times the multiplicand is to be used as an addend. The result is called the product. By the aid of the addition table the learner builds the multiplication table which he uses in future calculations. In this work he continues the use of objects. Henceforth multiplication becomes a distinct process and, from its original meaning it may be defined as the process of taking one number as many times as there are units in another. This implies that the multiplier must be an integer. The multiplicand is the number to be multiplied. The multiplier is the number with which the multiplication is made. The result is the product. (In the course of time the notion of multiplication became extended so that the multiplier might take a fractional form, hence a new definition became necessary. Under this conception, multiplication is the process of finding a number which bears the same relation to the multiplicand that the multiplier bears to unity.

The multiplicand may be abstract or concrete, but the multiplier must always be abstract, for it always tells how many *times* the multiplicand is to be used as an addend. The product is always of the same denomination as the multiplicand. The old statement that "feet multiplied by feet give square feet" is pure fiction, and has no place in mathematical teaching.

Numerically, the product is the same in whatever order the multiplication is performed,—this is called the Commutative Law of Multiplication.

Rule.— For convenience, write the multiplier under the multiplicand. Beginning with units, multiply each figure of the multiplicand by each figure of the multiplier, placing the right hand figure of each partial product under the figure used as a multiplier. Add partial products.

The figures of the multiplier may be used in any order whatever. The explanation of multiplication is practically the same as in addition.

Form of Analysis.— If one hat cost $6, what will be the cost of five hats?

Analysis: If one hat cost $6, five hats will cost 5 times $6, or $30.

Division is a special form of subtraction, and may be defined as the process of making several subtractions of the same number. The number from which the subtraction is to be made is the dividend. The number to be subtracted is the divisor. The number of times the subtraction can be made is the quotient. Under this conception, the dividend may be abstract or concrete, the divisor must always be of the same denomination as the dividend, and the quotient must always be an abstract number.

In its broader application, division is the opposite of multiplication, hence it may be defined as the process of finding one of two factors when the product and the other factor are known. Then there must be two definitions of division, viz.: Division is the process of finding how many times one number is contained in another of the same kind, or, Division is the process of finding one of the equal parts of a number. No division table as such, should be taught. When the learner ascertains that $6 \times 5 = 30$, he knows that $30 \div 6 = 5$, and $30 \div 5 = 6$. In this work objects should be used until the process is clear to the pupil.

When the divisor is 12, or less, the division is performed mentally and results written, and the process is Short Division. When all of the work is written, the process is Long Division.

Under the extended meaning of division, there must be two forms of analysis.

Forms of Analysis.— 1st. Form: If one hat cost $6, how many hats can be bought for $30?

Analysis: If one hat cost $6, as many hats can be bought for $30 as $6 is contained times in $30, or 5.

2d. Form: If 5 hats cost $30, how much will one hat cost?

Analysis: If 5 hats cost $30, one hat will cost $\frac{1}{5}$ of $30, or $6, or, If 5 hats cost $30, one hat will cost $30 ÷ 5, or $6.

Fractions.— There are two conceptions of a fraction. A fraction is one or more of the equal parts of a unit, or, a fraction is an expression ot division with the dividend above and the divisor below a horizontal line. $\frac{3}{4}$ is read three-fourths or three divided by four. It means that a unit has been divided into four equal parts and three of them taken, or it is simply an unexecuted division.

Objects should be used freely in teaching fractions. Let it be required to explain the two conceptions of $\frac{3}{4}$ by use of objects. Divide three apples among 4 boys, A, B. C, and D. Cut $\frac{1}{4}$ out of each apple and give the fourths to A, and to each of the others give one of the remaining parts. A will have $\frac{1}{4}$ of 3 apples, while each of the others will have 3 fourths of one apple. Therefore $\frac{3}{4}$ means 3 of the 4 equal parts into which a unit may be divided, or it may mean $3 \div 4$. Use objects in showing that $\frac{1}{2}$ is $2 \times \frac{1}{4}$, to show that multiplying the numerator multiplies the fraction, and the truth of other related rules, and to show the reduction of fractions to equivalent fractions having a common denominator.

$\frac{3}{5\frac{1}{2}}$ is not a fraction by the first conception, and must be read $3 \div 5\frac{1}{2}$

Fractions are simple, complex, or compound. A simple fraction is a fraction having integral numbers for its terms. A complex fraction is a fraction having a fraction in one or both of its terms, as

$$\frac{6}{8\frac{1}{3}}, \quad \frac{\frac{3}{5}}{\frac{1}{4}}$$

A compound fraction is a fraction of a fraction, as $\frac{2}{3}$ of $\frac{3}{4}$.

Fractions are further classed as common and decimal. A common fraction is a fraction whose denominator may be any number, as $\frac{3}{4}$ $\frac{7}{10}$. A decimal fraction is a fraction whose denominator is 10, or some power of 10, as $\frac{7}{10}$, $\frac{9}{100}$. When a decimal fraction is written with the aid of a decimal point it is called simply a *decimal.*

Compound Numbers.—The rules and explanations of compound numbers are the same as in simple numbers. The learner memorizes the tables and these tables take the place of the decimal scale.

Ratio.—Ratio is an expression of division with the dividend before and the divisor after a colon.

A ratio has two terms—the antecedent and the consequent. These terms must be of the same denomination. Ratios may be simple, compound, or inverse. A simple ratio is a ratio whose terms are single numbers, either simple or compound. A compound ratio is two or more simple ratios considered as one, shown by a brace, as

$$\left.\begin{matrix} 3:4 \\ 2:5 \end{matrix}\right\}$$

An inverse ratio is a ratio with its terms interchanged. 3:4 is the inverse of 4:3. All principles of divison and fractions apply to ratios.

A proportion is an equality of two ratios. A simple proportion is a proportion having both of its ratios simple. A compound pro-

portion is a proportion having one or both of its ratios compound, as

$$\left.\begin{matrix}3:4\\2:3\end{matrix}\right\} : 1 :: 2,$$

$$\text{or } \left.\begin{matrix}2:3\\3:5\end{matrix}\right\} : : \left\{\begin{matrix}1:5\\6:3\end{matrix}\right.$$

Three terms must be given to find the fourth. The first and fourth terms are called the extremes, and the second and third are the means.

Law.—The product of the means equals the product of the extremes.

Rule.—Write for the third term the denomination required in the answer. If from the nature of the question the answer is larger than the third term, the larger of the other two should be placed for the second term, and the smaller for the first term. If the answer is smaller than the third term the other two should change places.

Example.—If 3 hats cost $15, what will be the cost of 7 hats?

Solution.—3 hats : 7 hats : : $15 : ×

$$\times = \frac{7 \times \$15}{3} = \$35.$$

Explanation.—Will 7 hats cost more than 3 hats? Yes. Then 3 : 7 : : $15 : ×

Percentage embraces all operations with per cent. *Per cent means hundredths.* This is the only thing new in percentage. Per cent may be expressed with the sign, %, as a fraction, and as a decimal. 6% = $\frac{6}{100}$ or .06. The operator should change the per cent to a fraction or a decimal to suit his convenience. The terms of percentage are base, rate, percentage, amount, difference.

The base is the number upon which the percentage is calculated. The rate is the number of hundredths to be taken. The percentage is the result obtained from taking the per cent of the base and is of the same denomination as the base. The amount is the base plus the percentage. The difference is the base minus the percentage.

Principles: $B \times R = P$. $\frac{P}{B} = R$, $\frac{P}{R} = B$.

$\frac{A}{1+R} = B$ $\frac{D}{1-R} = B$

Profit and Loss are commercial terms and are always some per cent of the cost.

Stock is the capital of a corporation invested in business. A bond is a corporation's promise to pay money at a specified time. Market value, premium, discount, assessment, and dividend are all some per cent of the par value.

Commission.—An agent buys and sells for his principal. If he buys, his commission is some per cent of what he pays for it. If he sells, his commission is some per cent of what he receives for it.

Taxes. Tax is money collected by law for public use. Taxes are of two kinds,—direct and indirect. All local taxes are direct and are some per cent of the assessed valuation. The assessed valuation is a fictitious value placed upon property for the purpose of taxation. It may be above or below the real value.

Interest is money paid for the use of money, and is some per cent of the principal or amount borrowed.

Simple interest is interest on the principal only.

Annual interest is interest on the principal and on the unpaid annual interest.

Compound interest is interest on the principal and on all unpaid interest.

Discount is a deduction from a debt due at some future time, made for present payment. True discount is the simple interest on the present worth of the debt. The present worth of a debt is the sum of money which, if placed at interest for the given time at the given rate, will amount to the debt. If the debt is drawing interest, the amount due at maturity is the sum to be discounted. If the debt *is a note* given in a state which allows days of grace, days of grace should be counted in finding the true discount. In all other cases no days of grace are counted unless so stated in the problem.

Bank Discount is interest on the face of the debt for the given time plus three days. If the debt is drawing interest, the amount due at maturity is the sum to be discounted. Always count days of grace unless otherwise stated in the problem, or unless the note is dated in a state not allowing days of grace.

General Method.—All method should lead to clearness of thought, and to accuracy and speed in applying principles to the solution of problems. The student must image magnitudes and relations accurately and the method should lead to this result.

How can a pupil be expected to find the volume or convex surface of a pyramid if the image of the pyramid fails to present itself to his mind? If a pupil lack this power to image a magnitude, he must be required to represent it by a drawing. Many pupils fail in arithmetic because they attempt to memorize definitions and processes and thus work mechanically.

To as great an extent as possible the work of the class room must be made practical. The pupils must measure magnitudes, compute lengths, areas, volumes. To a limited extent the work of the carpenter, plasterer, bricklayer, stone mason, paper-hanger, may be taught by requiring the pupils to compute the cost of the blackboard, and the cost of carpeting the floor, the cost of papering the room, plastering the room, building a barn. The teacher's duty is to put a thought into the mind of the pupil, by suggestion if possible, and make it grow in interest and power. All principles and definitions should be developed and all results proved.

Ped'icel, the stalk of an individual flower. When a flower has no pedicel it is said to be sessile.

Pedom'eter, an instrument used for measuring walking distances by marking the number of steps taken. It is also so constructed as to mark the revolutions of a carriage wheel when attached to it.

Pe'dro, Dom, I., born near Lisbon in 1798, and died there in 1834, was the first emperor of Brazil and the second son of John VI. of Portugal. In 1807, he fled to Brazil with his parents on Napoleon's invasion of Portugal, and became prince regent of Brazil on his father's return to Portugal. For the proclamation of Brazilian independence and subsequent history, see BRAZIL.

Pe'dro, Dom, II., son of the foregoing, was born at Rio de Janeiro, Dec. 2, 1825, became king on his father's abdication in 1831, and was declared of age in 1840. During his long reign he was distinguished by his love of learning and scholarly tastes, and manifested no small degree of devotion to the welfare and prosperity of his people; but in the revolution of 1889, when Brazil was declared a republic, he was forced to abdicate his crown and withdraw to Europe. He died at Paris in 1891.

Pe'dro the Cruel, king of Castile and Leon, was born at Burgos, in Spain, Aug. 30, 1333. He was the only legitimate son of Alfonso XI., whom he succeeded in the year 1350. Three years after his accession to the throne, he married Blanche de Bourbon, sister of the French king, but soon deserted her for his mistress, Doña Maria of Portugal whose relatives he raised to the highest offices in his kingdom. Among many other victims of his cruelty, were two of his natural brothers, whom he put to death. At length, an insurrection was raised against him, under the leadership of his natural brother Henry. This he suppressed in spite of the excommunication of the pope, and the remainder of his reign was devoted to establishing his power and authority over his enemies, and to long and bloody wars with Aragon and Granada. In the year 1366, Henry, who had fled to France, returned at the head of a body of exiles, and revived his claims to the throne. Henry was supported by the pope, and also by Aragon and France; but Pedro, by promises of money and territory, secured the assistance of Edward the Black Prince, and totally defeated Henry at Navarrete, April 13, 1367. But Pedro so disgusted Edward by his cruelty to the vanquished, that the latter returned to France with his army, refusing any further alliance with a prince of such a character. In the autumn, Henry returned with an additional force, the people flocking to his standard. Pedro's army was completely routed at Montiel, March 13, 1369, and he himself taken prisoner. He was carried to a tent, where a single combat took place between him and Henry, in which Pedro was slain.

Pedun'cle, the general stalk of a flower cluster.

Peeks'kill, N. Y., a pretty and historic borough in Westchester county, on the Hudson river, and on the New York Central and Hudson River railroad, 43 miles north of New York city. It has a number of manufactories, stove-works, foundries, machine shops, shirt and cigar factories, flour mills, and blank-book and bookbinding establishments. The town has many fine churches, schools, a public library, military academy, convent, and an Episcopal school for young ladies, etc. Population 10,358.

Peel, Sir **Robert,** an eminent English statesman, was born near Bury, in Lancashire, Feb. 5, 1788. He entered the house of commons in 1809 as a Tory, and immediately began to show the diligence and prudence that were marked features of his character. He held the office of secretary for Ireland from 1812 to 1818, and in this position displayed such an unfriendly spirit toward the Catholics that they gave him the nickname of "Orange Peel," which clung to him through life. From 1818 to 1822, Peel was out of office; but in the latter year he reentered the ministry as home secretary; though in 1827 he retired. As home secretary, he distinguished himself by a reorganization of the London police force and by several other important measures. In 1829, Peel, as a member of the Wellington cabinet, proposed the bill for Catholic emancipation, and thereby separated himself from the Tory leaders with whom he had previously acted. The next year (1830) the Wellington-Peel ministry was succeeded by a Whig ministry under Earl Grey, and in 1832 the reform bill was passed in spite of Peel's vigorous opposition.

The general election of 1841 resulting in a decided victory for protection, Peel became prime minister with a large majority in both houses; but such was the demand for "cheap corn," that Peel was forced to yield to it and consented to the repeal of the corn laws. Peel retired from office in June, 1846, and, as a member of parliament for Tamworth, generally acted with the Whigs, whose free-trade principles he had fully accepted. He died at London in consequence of a fall from his horse, July 2, 1850. Peel declined a peerage and the order of the garter, and was universally respected for his ability as well as for his patriotism and high moral principle. See Guizot's *Robert Peel, Peel,* by J. R.

Thursfield, in the "Twelve English Statesmen" series, and Morley's *Life of Cobden*.

Pegasus (*peg'a-sus*), in Grecian mythology, the winged horse which sprang from the Gorgon Medusa when she was slain by Perseus. He is said to have received his name because he first made his appearance beside the springs (pegai) of Oceanus. When Bellerophon sought to catch Pegasus for his combat with the Chimæra, he was advised to sleep in the temple of Minerva, and during his sleep the goddess appeared to him and gave him a golden bridle, with which he caught Pegasus, and by her aid overcame the Chimæra.

Peking' or **Pekin'**, the northern capital of the Chinese empire, is situated on a sandy plain 100 miles from the sea (gulf of Pe-chili), and 60 miles from the great Chinese wall. The city consists of two parts—the northern, or Tartar city, and the southern, or Chinese city. The northern city is surrounded by a wall 60 feet high and from 40 to 50 wide, and the southern city by a wall 30 feet high and from 15 to 25 feet wide. The wall and moat are a little over 20 miles in length. Not counting the cross wall, the entire circuit measures about 21 miles, inclosing an area of about 25 square miles. In all, Peking has sixteen gates, over each of which is raised a tower 100 feet high, and of imposing appearance. Within the northern city is the Tsze-kin-ch'ing, or prohibited city, with a circumference of two miles, where the emperor has his residence. Peking has now railway communication with Tien-tsin, and with the gulf of Pe-chili at or near Taku.

Peking is one of the most ancient cities of the world. On the same site stood the metropolis of the feudal state of Yen, whose history can be traced back to the 12th century B. C. When Kublai Khan became emperor of all China, in 1280 A. D., he made Peking his capital, where he was found by Marco Polo. In the language of Dr. Williams "Peking stands to-day like the capitals of the ancient Roman and Byzantine empires, upon the debris of centuries of buildings." But little was known of the city, however, until the year 1860, when the English and French armies appeared before its walls and compelled the emperor to conclude the treaty of Tien-tsin or have his capital destroyed. Since that time the Chinese government has permitted ambassadors of other nations to have a residence in Peking, although they are not allowed to enter Tsze-kin-ch'ing, the Forbidden City. For an account of the attack on and siege of the foreign legations at Peking, in the summer of 1900, and the investment of the city by the armies of the foreign powers, see article on the Boxer Rising. The population of Peking is variously estimated at from 1,300,000 to 1,500,000. See Williamson's *Journeys in North China*, and Williams' *The Middle Kingdom*; also Martin's *The Siege in Peking*.

Pelagius (*pē-lā'ji-us*), the founder of the religious system known as Pelagianism, was born about the middle of the 4th century in Britain, or, as some suppose, in Brittany. He went to Rome about the year 400, where he showed considerable zeal and activity in seeking to reform the clergy and laity. Jerome and Orosius tell tales to his discredit, but Augustine always speaks of his character and conduct with respect. With his disciple, Cœlestius, he went to Carthage in 411, where Cœlestius was accused of heresy before a synod held in that city and condemned for the following doctrines: 1. Adam was created mortal, and would have died, even if he had never sinned. 2. Adam's sin affected only himself, and not his posterity. 3. Infants are born in the same condition as Adam was before he sinned. 4. The human race does not die in consequence of Adam's sin, and does not rise from the dead on account of Christ's resurrection. 5. Infants are saved whether baptized or not. 6. Men may be saved by obedience to the law as well as by the gospel. 7. There were men who lived without sin even before the appearance of Christ upon the earth. Meantime, Pelagius had gone from Carthage to Jerusalem, and in 415 he too was accused of heresy before the synod of that place. The matter was referred to Pope Innocent, but at another synod of 15 bishops, held the same year at Diospolis, Pelagius was acquitted. But a new synod of Carthage, in 416, condemned both Pelagius and Cœlestius, and its sentence was approved by Pope Innocent. Zosimus, the successor of Innocent, was induced to declare the two accused persons sound in the faith; but a council of 214 bishops was held at Carthage, in which the doctrines of Pelagius were formally condemned in nine canons, and Augustine appealed to the emperor, Honorius, who ordered the new heresy to be suppressed. Zosimus also published a decree approving the canons of the council held at Carthage, and requiring all bishops to sign them on pain of losing their office. Nineteen Italian bishops, under the leadership of Julian, bishop of Eclanum, refused to do so and were deposed. Pelagius himself was banished from Rome by the emperor, Honorius, and he and Cœlestius were again condemned by the council of Ephesus. The date and place of the death of Pelagius are not known.

Pelas'gians, a term applied to the most ancient inhabitants of Greece, Italy, and some portions of Asia Minor. In Homer, the Pelasgi seem to have been an unimportant tribe living in Thessaly. Herodotus seems to regard them as a race of barbarians who had occupied Hellas prior to the Hellenes. Thucydides, on the other hand, says that they were the most numerous of the various races that inhabit Greece. Amid such conflicting

testimony it is impossible to form any definite conclusions in reference to the Pelasgians; but we are at least justified in regarding them as an active and stirring people, chiefly intent upon agricultural pursuits. Yet they were no less brave and determined when attacked and driven to self-defense.

Pelew' Islands, a group of about twenty-five islands (now under the protection of Germany), lying southeast of the Philippine islands in the Pacific ocean, at the western extremity of the Caroline archipelago. These islands are mountainous, wooded, and are surrounded with coral reefs. Total area, 170 square miles. The inhabitants, about 10,000 in number, belong to the Malay race. The soil is fertile, and the climate healthy. The Pelew islands were discovered by the Spaniards in 1543, and sold to Germany in 1899.

Pel'ican, a water bird with webbed feet, and a long bill having a pouch on the under surface. The upper part of the bill hooks over the lower. Pelicans are large birds with powerful wings. They occur in both the Old and New Worlds, being mostly confined to the tropics and warm parts of the temperate region. North America has a single species — the white pelican. In warm summers, it breeds as far north as Nevada. They live upon fish, and at times, the pouch on the lower jaw is greatly distended with fish stored up to be eaten at leisure. The gannet and cormorant are related birds.

PELICAN.

Pelissier (*pā'lē'sē-ā*), **Aimable Jean Jacques,** a marshal of France, was born at Maromme near Rouen, Nov. 6, 1794. He entered the French army at the age of twenty; and after 36 years' service attained the rank of general in 1850. In the Crimean war, in 1855, he was placed in command of the first corps, and soon succeeded Marshal Canrobert in the chief command before Sebastopol. On the 8th of September he stormed the Malakoff, for which he was rewarded with a marshal's baton, and after the fall of Sebastopol he was also created Duc de Malakoff, and rewarded with a grant of $20,000. He died at Algers, May 22, 1864.

Peloponnesus (*pel-ō-pon-nē'sus*), a peninsula, now called the Morea, which formed the southern part of ancient Greece, so called by the Greeks, because King Pelops is said to have settled a colony there. It is about 140 miles long and nearly the same distance in extreme breadth. It is connected with northern Greece by the Isthmus of Corinth, which separates the gulf of Corinth from the Saronic gulf. The surface of the Peloponnesus is quite mountainous, the mean height of its mountains being about 1,000 feet. In the center a lofty circular ridge incloses an elevated basin, the famous vale of Arcadia. Among its ancient cities were Sparta, Argos, Mycenæ, and Mantinea. After the Messenian war, Sparta acquired supremacy over the other states, and three centuries later (431–404 B.C.) occurred the two Peloponnesian wars, which were mainly a contest for supremacy between Athens and Sparta, although many other states were involved in the conflict. In modern Greece, the term Peloponnesus is applied to a group of monarchies or provinces, which embrace among others Argolis and Corinth, Achaia and Elis, Arcadia, etc. Its area is about 8,000 square miles, with a population of nearly 860,000.

Pe'lops, in Grecian mythology, the grandson of Zeus and the son of Tantalus. His father invited the gods to a banquet, and, in order to test their superior knowledge, killed Pelops and served his remains at the table. They were not deceived and refused to touch the horrible food set before them; but Dementer, absorbed with grief for the loss of her daughter, ate part of a shoulder without knowing what kind of flesh it was. The gods then ordered the remains to be thrown into a cauldron, out of which Clotho brought the boy alive, an ivory shoulder being given to him in place of the one that had been eaten. Hence his descendants, the Pelopidæ, are said to have one shoulder white.

Pel'tier, Jean Charles Athanase, a French physicist, was born at Ham (Somme) in February, 1785; and died at Paris, in Oct., 1845. His father educated him for the watchmaker's trade and sent him to Paris. In 1815, he came into a fortune, which was moderate, but which enabled him to retire from business and devote himself to science. For some years he studied anatomy and microscopic animalcules; then turned his whole attention to electricity. In 1834, he made his great discovery, namely, that the junctions in a circuit of metals are heated or cooled according to the direction in which an electric current is made to flow through the circuit. If a current from an outside source is passed through a circuit of two metals, it cools one junction and heats the other. Seebeck, in 1822, had already discovered the converse of the "Peltier effect," namely, that if a circuit of two metals have its junctions maintained at different temperatures, an electric current is produced in the circuit.

Pem'mican, a kind of condensed food made by cutting lean meat into thin strips, and after thoroughly drying them, reducing them to powder and mixing the substance with boiling fat. It is much used by Arctic voyagers.

Pen (from the Latin *penna*, "a feather"), an instrument for writing with fluid ink. When the ancients wrote upon papyrus or parchment they used a reed pen, and when they used tablets of wood or stone they wrote upon them with a pointed stylus of bone or other material. Reed pens are still used by the natives of Persia and some other countries, as a metal pen does not suit their mode of writing. The Chinese and Japanese write with a small brush or hair pencil. When paper was introduced into Europe for writing purposes quill pens came into general use, and so continued down to the beginning of the 19th century.

The first English patent for the manufacture of steel pens was issued to Bryan Donkin in 1803; but the credit of bringing them into general use should be divided among four men—James Perry, John Mitchell, Joseph Gillott, and Sir Josiah Mason. Perry began pen-making at Manchester in 1819, using the best Sheffield steel for the purpose. He removed to London and had developed the pen trade to tolerably large proportions before the Birmingham manufacturers caused a revolution in the trade by the invention of machinery in the manufacture of pens, thus enabling them to be sold cheaply and to become articles of common use. The growth of the pen trade may be seen from the fact that in the year 1886 the weekly average of pens manufactured in Birmingham was over 2,000,000. The manufacture of gold pens has progressed to a much greater extent in the United States than in any other country, the annual product amounting to nearly $2,000,000 in value. The gold pen goes through no less than forty-five processes, from the gold bar purchased from the United States assay office to the highest finished article of commerce. To give hardness to the point of the pen it is tipped with iridium. The United States imports half a million gross of steel pens annually and manufactures nearly two million gross at Camden, Meriden, and Philadelphia, the steel used being chiefly imported from Birmingham. In the stylograph or fountain pen the nib is dispensed with, a finely tapered point connecting with the barrel containing the ink. The first fountain pen was brought out in the year 1848.

Penang', an island in the strait of Malacca, lying off the Malay peninsula, between it and Sumatra, belonging to Great Britain. With Singapore, Wellesley, and Malacca, it forms a crown colony, known as the Straits Settlements. It comprises an area of 107 square miles and contains 235,618 inhabitants. The coast of the island is very irregular, being indented by several bays. The surface is intersected by a mountain range, the highest point of which is about half a mile above the level of the sea. The soil is very fertile, and rice, tapioco, pepper, cloves, nutmegs, and other tropical fruits and vegetables are grown. Georgetown, in the northern part of the island, is the capital. It has a good harbor and considerable trade. The native states of the Malay peninsula, adjoining, are under British protection, and contain the richest tin fields in the world, besides valuable forests yielding rubber, gutta-percha, and gums.

Pen'cil. A slender stick of black lead, slate, or chalk, inclosed in a round piece of wood, is called a pencil, but the term is also applied to small hair brushes, used by artists, and it is to these that the name was originally given. For a long time the graphite or plumbago from the Cumberland mines, in England, furnished the "leads" for the best pencils ever made; and since these mines were exhausted, vast quantities of the same material have been found in Siberia. By a method, patented by Mr. W. Brockedon in 1843, this material is freed from impurities by first grinding it to powder, and then formed in solid blocks by subjecting it to heavy pressure in cases from which the air is removed. The manufacture of black lead and colored pencils is carried on extensively at Nuremberg, where there are more than twenty factories, which employ several thousand hands and produce annually about 250,000,000 pencils.

Pen'dulum, literally a hanging body, is used in physics to denote any body performing isochronous, or nearly isochronous, vibrations. Thus a magnet freely suspended so as to vibrate in a horizontal plane is sometimes called a *magnetic* pendulum. An ordinary clock pendulum is called a *gravitational* pendulum. A brass rod, suspended by a wire so as to vibrate in a horizontal plane, is generally known as a *torsion* pendulum. Space permits us here to discuss only the gravitational pendulum. This simple but elegant instrument serves two principal purposes, each of which was first pointed out by the great Dutch physicist, Huygens (1673). One of these uses is that of a time-measurer, an application based on the fact that, so long as a pendulum remains of constant length and swings through the same angle, it vibrates at a constant rate. In practice its length is kept constant by "compensation" and its angle of swing is kept constant by means of a spring which gives it a little push at each vibration. (See CLOCK.) The second use of the pendulum is as an instrument for measuring the acceleration of gravity at various points over the surface of the earth. This is generally done in one of two ways, namely, either by suspending a heavy metallic sphere of known radius by means of a fine wire of known length, and observing the period of vibration; or by suspending a bar of metal from one of two points such that it has the same period of vibration from whichever point it be suspended. The former method is a near approximation of what is called a *simple* pendulum, namely, a heavy particle suspended by a massless thread; the latter is a *revers-*

ible compound pendulum. It can be proved, by dynamics, that the period, T, of a simple pendulum whose length is l, is given by the equation

$$T = \pi \sqrt{l/g}$$

where g is the acceleration of gravity at the place of observation. Using this equation for the brass ball, suspended by a wire, and making some slight corrections for the wire and for the diameter of the ball, one may obtain a very accurate value of the acceleration of gravity. This method is due to Borda. In the case of the reversible pendulum it can be shown that the distance between the two points of suspension is exactly equal to the length of a simple pendulum which would vibrate with the same period. Hence, to obtain g with great accuracy, one has only to measure this distance, which we may call l, determine the period, T, and solve for g the equation given above.

The pendulum is frequently employed also to compare the acceleration of gravity at several different places. Here we may disregard the length of the pendulum, *provided this remains constant*, since the ratio of the acceleration at two stations depends only upon the square of the ratio of the periods at the same two stations. For this purpose the United States Coast Survey uses pendulums which are very short and convenient, beating quarter-seconds.

Penguin (*pĕn'gwĭn*), a swimming bird peculiar to the southern hemisphere. Their wings are paddle-shaped, and while they do not suffice for flying, they are used in swimming and brought into use alternately. In diving and swimming under water, the wings only are used, the feet being used as a rudder. The feet are placed so far back on the body that the bird is erect when standing. They have a smooth scale-like plumage adapted for slipping through the water. These birds live mostly on the water and go on shore only to breed. During the breeding season, they are found in great numbers on rocky islands far from habitations, as on the Falklands, the Kerguelen islands, and rocky parts of New Zealand. There are three kinds, the king penguins, the jackass penguins, and the rock-hoppers. The king penguin stands about three feet high, and some other species are about one-half that size.

KING PENGUIN.

Penin'sular War. The quarrels between Charles IV., king of Spain, and his son, Ferdinand, in 1807, gave Napoleon an opportunity of interfering in the affairs of that country. In pursuance of a treaty made with Charles he had sent an army into Portugal under Junot, by whom Lisbon was seized, and the members of the royal house obliged to flee to Brazil. For the pretended purpose of supporting Junot's army other French troops occupied Valladolid, Salamanca, and other important positions in Spain, including Madrid, where Murat was in command. Riots at Madrid, Toledo, and other places caused the feeble king such alarm that he surrendered his crown to Napoleon, who at once bestowed it upon his brother Joseph, then king of Naples. Joseph Bonaparte was accordingly proclaimed king of Spain in Madrid, July 24, 1808. But the Spanish provinces refused to recognize Joseph, and rose against the French in all directions. Assistance was supplied to the patriots of Spain and Portugal by Great Britain; and on the 12th of July, 1808, Sir Arthur Wellesley (afterward duke of Wellington) was sent to Portugal with 30,000 men. Wellesley defeated Laborde at Rolica and Junot at Vimiera, but then turned over the command to Sir Harry Burrard, who had been sent out to supersede him, to be himself superseded within a few hours by Sir H. Dalrymple. The latter officer concluded the convention of Cintra with the French, who evacuated Portugal during September, 1808. But Napoleon continued to send large re-enforcements to Spain, and came to Madrid to direct the operations of his forces; and when Sir Arthur Wellesley was again sent out, in the spring of 1809, he found himself confronted by nearly 400,000 French troops, in eight corps d'armée, commanded by six marshals and by Generals Junot and St. Cyr. Wellesley at once proceeded to active operations; but it took a conflict of five years and many hard-fought battles to drive the French forces out of Spain. For his services in this war, Wellesley was created duke of Wellington, and received a grant of $2,500,000 from the English parliament.

Penn, William, founder of the colony of Pennsylvania, was the son of Admiral William Penn, and was born at London, Oct. 14, 1644. Penn studied at Christ Church, Oxford, and while there became a convert to Quakerism by the preaching of a disciple of George Fox, named Thomas Loe. In 1668, Penn was thrown into the Tower on account of a publication entitled *The Sandy Foundations Shaken*, in which he attacked the doctrines of the trinity, God's "satisfaction" in the death of Christ, and justification by the imputation of Christ's righteousness. While in prison he wrote the two most famous and popular of his books, *No Cross, No Crown*, and *Innocency with Her Open Face*, a vindication of himself, which contributed to his

liberation through the influence of the Duke of York. In September, 1670, Admiral Penn died, leaving his son an estate of $7,500 a year and certain claims upon the government for $80,000. In 1672, Penn married Gulielma Maria Springett, daughter of Sir William Springett, and for some years thereafter continued to advocate the doctrines of Quakerism by preaching and writing.

In 1681, in lieu of his monetary claim upon the government, he obtained a grant of territory comprising the present state of Pennsylvania. He desired to call it Sylvania, but King Charles II. insisted on the prefix Penn, in honor of his father. Penn sailed for the New World in September, 1682, and in October held his famous interview with the Indian tribes under a large elm tree, on the ground where Philadelphia now stands. In this interview, Penn concluded a peaceful arrangement with the Indians for the purchase of their lands, and for fifty years afterward his colony was unmolested by them. Penn planned and named the city of Philadelphia, and for two years managed the affairs of his colony in the wisest, most benevolent, and liberal manner. Not only Quakers, but persecuted members of other religious sects, sought refuge in his new colony, where the principle of religious toleration was fully recognized and respected.

Toward the end of the reign of Charles II., Penn returned to England to exert his influence in favor of his persecuted brethren at home, in which he was so far successful that soon after James II. came to the throne, in 1685, 1,200 imprisoned Quakers were set at liberty. After the accession of the Prince of Orange, Penn was accused of treason and conspiracy, but was acquitted. In 1699, Penn paid a second visit to the New World, where his colony required his presence, on account of the arbitrary behavior of his deputy. His stay, which lasted two years, was marked by many useful measures and by efforts to improve the condition, not only of the colonists, but of the Indians and negroes also. He returned to England in 1701, on account of the condition of his finances in that country, which had been left in charge of an agent named Ford. When Ford died, he left claims against Penn which the latter refused to pay, and was committed to the Fleet prison, where he remained until his friends procured his release by settling the claims against him. In 1712, he was stricken with paralysis, from which he never recovered, although his death did not take place in Berks, England, until July 30, 1718.

Pen'nel, Joseph, an American artist and engraver, was born at Philadelphia in 1860. He married Elizabeth Robbins, and he and his wife have been almost continuously traveling, writing and sketching since 1885. In this time they have visited many of the cities and sailed down most of the historic rivers of the Old World. Mr. Pennel's works are very numerous, all illustrated in that pen-and-ink style for which he is justly famous. His first book was *A Canterbury Pilgrimage* (1885); the last, *The Work of Charles Keene* (1897). Mr. Pennel and his wife at present (1901) reside in London.

Pennsylvan'ia, one of the original thirteen states, and since 1830 the second state of the Union in population, is a parallelogram in shape, being about 300 miles in length and a little more than half that distance in width. It is bounded on the north by Lake Erie and the state of New York; on the east by New Jersey, from which it is separated by the Delaware river; on the south by Delaware, Maryland, and West Virginia; and on the west by West Virginia and Ohio. Pennsylvania is naturally divided into three unequal portions, the first being the southeastern part of the state, which extends from the Delaware river to the Blue mountains. This region comprises the Cumberland valley, extending without a barrier to the sea and famous for its fertile soil and vast mineral resources. The Appalachian system of mountains, which crosses the state from northeast to southwest in a belt from 75 to 150 miles wide, may be classed as the second division. This system of mountains, besides the Blue or Kittatinny range on the east and the Alleghenies on the west, contains a number of minor chains or ridges. These minor ranges are interspersed with many broad and fertile valleys, and the rivers have, in some places, cut gaps through the ridges, affording passages for travel and commerce. The third division of the state is the western plateau, comprising about half its area, and extending from the western slopes of the Alleghenies toward the Ohio river, New York, and Lake Erie. This region is crossed by a few ridges and has several isolated peaks, such as Towanda mountain, Blossburg mountain, and Crooked Creek mountain. It contains a large number of pine and hemlock forests, and furnishes a vast amount of lumber to eastern markets.

Western Pennsylvania is noted for the vast quantities of bituminous coal and of iron ore that is mined within its limits, the city of Pittsburg being the chief center of the iron industry. The beds of anthracite coal between the Delaware and Susquehanna rivers are practically inexhaustible, it being estimated that even the present vast output of 25,000,000 or 30,000,000 tons a year would not exhaust the supply for several centuries. The anthracite coal region covers an area of about 500 square miles, the most important deposits lying in what are known as the southern, middle, and northern fields. In 1899, the state output of rolled iron and steel was in volume over seven million tons, of which Allegheny county furnished more than half. In the same year, the anthracite coal output exceeded sixty million tons, while the output of bituminous coal was close upon

seventy-five million tons. Several million barrels of petroleum are produced in the state every year.

Educationally, Pennsylvania ranks high among the states of the Union. In 1899, the state had nearly 15,000 public school buildings, with 29,000 teachers and a pupil enrolment of 1,186,146. There were also in the state 300 high schools, besides a large number of professional colleges and schools. At Philadelphia is the University of Pennsylvania, and at Allegheny the Western University of Pennsylvania. In other sections of the state there are over 30 universities and colleges belonging to the different denominations.

Pennsylvania is second only to New York in the product of her manufactures, while the annual product of her mines is nearly equal in value to that of all the other states of the Union. Eastern Pennsylvania is drained by the Delaware and the Susquehanna rivers and their tributaries, and western Pennsylvania by the Allegheny and the Monongahela, which unite their waters at Pittsburg, and form the Ohio. There are nearly 10,400 miles of railroad in the state, the greater portion of which is owned and controlled by the Pennsylvania and the Pennsylvania and Reading companies. The area of Pennsylvania is about 45,215 square miles. Population 6,302,115.

Peh'ny, an English coin, one-twelfth of a shilling in value, first mentioned in the laws of Ina, king of the West Saxons, about the close of the 7th century. It was at this time a silver coin, and weighed 22½ grains, being about $\frac{1}{240}$ of the Saxon pound weight. Halfpence and farthings were not coined in England till the time of Edward I., but the penny was indented with a cross-mark, so that it could easily be broken into either two or four parts. The penny steadily declined in weight until the reign of Elizabeth, when it was fixed at $7\frac{7}{11}$ grains, or $\frac{1}{62}$ of an ounce of silver, a value to which the copper pennies, first introduced in 1797, closely approximated. The present penny is made of bronze, and is of only half the value of the copper penny, for which it has been substituted.

Penob'scot, the largest river in Maine. The west branch rises near the Canada line, and flows east and southeast to the town of Medway, where it meets the east branch, or Seboois river. Afterward its course is southwest to Penobscot bay, an inlet of the Atlantic ocean on the southern coast of the state. The Penobscot is navigable for large vessels to Bangor, 60 miles from its mouth. Its upper waters are used for floating logs from the forests of northern Maine to Bangor and other points, where they are sawed into lumber. The length of the Penobscot is 300 miles, and it is the most important navigable stream in the New England states.

Pensacola (*pen'sȧ-kō'lȧ*), a city and port of entry of Florida, the capital of Escambia county, 250 miles from New Orleans, on the west shore of a deep bay opening into the gulf of Mexico. Near by, is the Pensacola navy yard, with a marine hospital and barracks. Pensacola was settled by the Spaniards be-

fore 1700, occupied by the British from 1763 to 1781, and afterward, during the wars with Napoleon, taken from them by Andrew Jackson in 1814, and in 1819, with the remainder of Florida, became a part of the United States. Population 17,747.

Pen'sions, the regular allowances of money paid to individuals by a government in return for services, civil or military. Most European governments have both a civil and a military list; but in the United States military service alone constitutes a claim for pension. In general, pensions are granted only for active service in time of war and for injuries received during such service. "Service pensions" were granted to all survivors of the Revolutionary war by act of 1818, to all survivors of the War of 1812 by act of 1871, and to the survivors of the Mexican war by act of 1887. But the bulk of United States pensions are "invalid pensions" for wounds or disability incurred in service. These extend to the widows, and children under sixteen years, of those who died from such wounds or disease; or, in the event of there being no such surviving widow or children, then to dependent fathers or mothers or minor brothers and sisters of men so dying. The pensions, which range from $24 to $2,000 a year, are graded according to the rank of the pensioner and the degree of his disability. Thus, where the regular aid or attendance of others is required, from $50 to $72 a month is allowed; where the pensioner is incapacitated for manual labor, $30 a month; for the loss of a hand or foot or total deafness, $30 a month; for the loss of both feet or hands or both eyes, $72 a month, and for amputation at the shoulder or hip joint, $45 a month.

In addition to these provisions for injuries incurred in the service, by the law of June 27, 1890, all persons who served ninety days or more in the army or navy of the United States during the Civil war, and were honor-

ably discharged therefrom, and who are now suffering from any permanent disease or disability, not the result of their own vicious habits, which unfits them from earning their support by manual labor, are allowed a pension of from $6 to $12 a month, according to the degree of disability. By the same law, the widow of any such soldier, without other means of support than her daily labor, shall receive $8 a month during her widowhood, provided she married such soldier prior to June 27, 1890.

An independent bureau for the transaction of the pension business of the government was established in 1833, and in 1849 it was made a bureau of the department of the interior. The commissioner of pensions is appointed by the President, and under him there are about 2,000 persons employed in the examination and settlement of pension claims; and there is an equal number of surgeons throughout the country whose duty it is to examine all applicants ordered to appear before them.

The growth of the pension system of the United States government, and its liberality toward its soldiers and sailors, may be seen from the following figures: In 1862, the amount of money paid out for pensions was less than $1,000,000; in 1872, ten years later, it exceeded $30,000,000; in 1880, it was $57,240,540; for the year ending June 30, 1890, it was $109,357,534; for the year ending June 30, 1891, it was $116,972,172; for the year ending June 30, 1899, it was $142,502,570. The total number of pensioners on the roll at the latter date was 993,529. Owing to the casualties in the war with Spain, the secretary of the interior asks for a pension vote, for the year ending June 30, 1902, of $145,245,000.

Pen'tateuch (*tūk*) (from the Greek words *pente*, "five," and *teuchos*, "book"), the name given by the Christian fathers to the first five books of the Bible—Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. The Jewish name given to these books was *Torah*, meaning "the law." In connection with the book of Joshua these five books really form one continuous work, called by many modern schools the *Hexateuch*.

Pe'onage, a system of servitude common in Mexico and some Spanish-American states. By the Spanish colonial system, the peon in debt to his employer was bound to labor for him until the debt was paid. It is claimed that under this system employers often contrived to keep their laborers in continual servitude by advancing them money for needless expenditures or selling them goods on credit and at high prices. Peonage in the territory of New Mexico was abolished by act of congress in 1867. It has also been abolished in the Argentine republic, and some other South American countries.

Peo'ria, Ill., a large and enterprising city on the Illinois river, 62 miles north of Springfield, and 160 miles southwest of Chicago. It is an important railway center, the union depot being used by ten of the railway lines that meet at this point, and is connected by seamboat navigation with the Mississippi. It contains a Roman Catholic cathedral, a high school, a medical college, and three hospitals. There are ten parks within the city's limits, the largest (Jefferson) containing 35 acres. Population 56,100.

Pep'in le Bref ("the short"), son of Charles Martel and father of Charlemagne, was born in 714. Charles Martel, before he died, divided his kingdom between his two sons, Carloman and Pepin, the former taking the German part, the latter Neustria and other portions of northern France; still they were only rulers in the name of the Merovingian king. St. Boniface, in 751, crowned Pepin king of the Franks, Childeric, the last king of the Merovingians, having been deposed; and when Pope Stephen III. was hard pressed by the Lombards under Aistulf, in 754, he came to France to solicit help from Pepin. The latter led his army into Italy, compelled Aistulf to become his vassal, gave to the pope the title of exarch of Ravenna, thus first establishing the temporal sovereignty of the holy see. He died in 768, and his two sons, Carloman and Charlemagne, divided his territories between them.

Pep'per, William, an American physician, educator, author, and benefactor, was born at Philadelphia, Aug. 21, 1843, and educated at the University of Pennsylvania, from which he took both his classical and his medical diplomas. Within four years after receiving his degree as a physician, he was appointed lecturer in the same college, and he was connected with the university up to the time of his death. He was elected provost of the university in 1881; and during his incumbency of thirteen years it became a new institution, one of the foremost in the states. So great was his devotion to the university, that he not only gave his services free, but contributed many thousands of dollars out of his own private fortune toward its various endowments. His health suffered from too constant application, and in 1894 he retired, removing to California, where he died July 28, 1898.

Pep'sin, a substance contained in the gastric juice and the mucous membrane of the stomach, to which the gastric juice largely owes its power of dissolving the contents of the stomach, and converting them into chyme. Various plans have been devised for extracting pepsin from the stomachs of calves, pigs, and other animals; but it has never yet been obtained in its purity, and its chemical constitution is unknown. Pepsin has been used to a considerable extent in medical practice, in cases of weak or disordered digestion; and it is an ingredient in most of the digestive preparations now in the market.

Pepys (*pēp'is*) **Samuel**, a notable English diarist, born in 1633, and died in 1703. His famous *Diary* deals with the era of the Restoration, and is replete with minute and curious facts concerning the times in which its author lived. The *Diary* was written in cipher, and was not discovered and published until 1825.

Pequots (*pē'kwŏts*) or **Pe'quods**, a tribe of North American Indians, a branch of the Mohicans, who inhabited the country around the Thames river when Connecticut was first settled by the English. It is supposed they branched off from the Hudson river Mohicans at the beginning of the 17th century. They soon conquered most of the tribes in Connecticut, and made treaties with the Dutch and English. But afterward, becoming hostile, an expedition was sent against them from Hartford in 1637. A Pequot fort, near the present town of Groton, was attacked and fired, and in the struggle amid the burning wigwams, several hundred men, women, and children perished. The war continued until the tribe was nearly annihilated at Fairfield swamp. The remnant was either sold as slaves or scattered among the neighboring tribes, but a small number were afterward gathered into bands in Ledyard and North Stonington; and at this day there are a few descendants of the Pequods living at Green Bay, Wis.

Perch, a fresh-water fish generally distributed in Europe, the eastern United States, and northern Asia. There are about one hundred species in the perch family. The common yellow perch of Europe and the eastern United States, is the type of those of moderate size. The American form is dark olive-green above, with golden-yellow sides crossed by six or eight dark bars; the lower fins are orange and the upper ones dark green. A few larger fishes, called pike-perches,

PERCH.

also belong to the family. The wall-eyed pike is a perch, not a pike. It is one of the most important food fishes of the lake region, and is abundant in Saginaw bay. It attains a length of three feet, and a weight of ten to thirty pounds. In contrast with these large fish, the perch family includes a number of darters too small to be of use as food.

Per'cival, James G., an American poet and geologist, was born at Kensington, Conn., Sept. 15, 1795, graduated at Yale college in 1815, and afterward entered the medical profession. Having removed to Charleston, S. C., in the year 1822, he there published his two poems, *Prometheus* and *Clio*. Two years later, he was appointed professor of chemistry at West Point, but finding the duties of this position too heavy and irksome, he soon resigned and was made surgeon in connection with the recruiting service in Boston. In 1827, he moved to New Haven, where the third part of *Clio* was published. Percival afterward divided his attention between poetry and geology, and as he grew older he gave more and more time to the latter. In 1835, he and Professor Shepard were appointed to make a geological survey of Connecticut, his report of which was published in 1842. He was appointed geologist of Wisconsin in 1854, and died at Hazel Green in that state, May 2, 1856.

Percy, the name of a distinguished English family, descended from William de Percy, who accompanied William the Conqueror to England in 1066, and received large grants of land from that sovereign.

Peren'nial Plants, those which live from year to year, either by the persistence of their stems, as in the case of shrubs and trees, or by the persistence of underground parts. The actual duration of such plants is exceedingly variable, the term simply meaning that they do not disappear entirely within one or two years. They may endure a few years or hundreds of years. See DURATION.

Perfectibil'ity or **Perfec'tionism** is the doctrine that man in a state of grace may attain to perfection and live without sin in this life. Catholics hold that no one, except by special privilege of God, as in the case of the Blessed Virgin, can live without sin altogether. Among Protestants, Wesleyan Methodists, and some other sects believe in the possibility of a Christian perfection attainable in this life. Most believers in the doctrine, however, define perfection not as that state which admits of no further growth, or progress, but rather as the beginning of growth in grace and the knowledge of the truth. Most Protestant sects, however, deny that man can attain perfection in this life, even by the assistance of divine grace.

Perfec'tionists, also called Communists and Free-Lovers, a small American sect founded by John Humphrey Noyes, who was born at Brattleboro, Vt., Sept. 6, 1811. Noyes practiced law a number of years and then became a Congregational preacher. Experiencing a second conversion, he claimed that the prevailing theology is all wrong, and separated himself from the Congregational church. He held that the gospel, if accepted, secured entire freedom from sin; that God has a dual being (male and female); that the author of evil is uncreated but is not God; and that communion with Christ not only

saves from sinning, but also from disease and death. He and his converts formed a Perfectionist church or community at Putney, Vt., afterward moving to Oneida, N. Y. Men and women put their property into a common stock; they gave up all formal prayer and religious service and the observance of the Sabbath; those who were married renounced their marriage ties, and a "complex marriage" was established between all the males and all the females of the "family." Having as far as possible dispensed with law, he set up public opinion as a controlling power in its place; and free criticism of one another by the members of his sect became a marked feature of his system. In 1880, the pressure of outside influence caused the community to change their mode of life in many respects. Marriage and the ordinary family relationship was introduced; communism of property gave place to a joint-stock company organization, and various co-operative institutions were also established. Noyes, who assisted in making these changes, died at Niagara Falls, April 13, 1886.

Perfum'ery or **Per'fumes,** the delicate smells arising from certain odoriferous bodies. Perfumes are of two distinct classes: those derived from plants and those of animal origin. Of vegetable perfumes, the most ancient are those gum-resins which exude naturally from the trees and plants, or from wounds inflicted to increase the yield. Among the most important gum-resins are myrrh, benzoin, and camphor. Gum-resins form the chief ingredients in incense and pastilles.

A second group of vegetable perfumes are those procured by *distillation*. These were formerly termed quintessences, but are now called ottos, from the Turkish word *attar*, applied to the attar or otto of the rose. The process of distillation is a simple one. The fragrant part of the plant is put into the still and covered with water; and when the water boils the ottos arise with the steam, from which they are separated by decanting. By this process, 100 pounds of orange or lemon peel will yield about ten ounces of the fragrant oil; 100 pounds of nutmeg will yield 60 to 70 ounces of oil of nutmeg; other substances in various proportions.

But as it has been found that many flowers do not yield their essential oil by distillation, two other processes have been devised for obtaining it, namely, *enfleurage* and *maceration*. In the former of these processes square boxes with glass bottoms are provided upon which is spread a mixture of lard and suet, which has been melted and clarified for the purpose. Fresh flowers are spread every morning upon this grease, the box being kept closed until the grease absorbs their odor. When the grease has been "enflowered" in this way, the process generally lasting three weeks or more, it is again melted and strained into canisters, and is then ready for use. Perfumes are also obtained from flowers by maceration, that is, by placing them in oil or melted fat for several hours, and by continuing the process with new flowers until the oil or fat becomes fragrant with their odor. The best-perfumed grease is obtained from some flowers by enfleurage, and from others by maceration, while others will produce the most satisfactory results by both processes — enfleurage followed by maceration.

Some extent of the flower industry may be obtained from the following figures showing the weight of certain flowers grown in the south of France in the year 1889: Orange blossoms, 1,860 tons; roses, 930 tons; violets, 147 tons; jasmine, 147 tons; tuberose, 74 tons. Europe and British India alone consume about 150,000 gallons of handkerchief perfumes yearly. The English revenue from French eau de cologne is $40,000 a year, and from other imported perfumes $200,000.

The principal perfumes of animal origin are musk, civet, ambergris, and castor, of which musk is most highly prized. The aroma of musk imparts odor to every body or thing with which it comes in contact. Its power to impart odor is so great, that polished steel will become fragrant with it, if they are both placed in a closed box for a sufficient length of time. In the manufacture of perfumery, tincture of musk is mixed with other odorous bodies to render the scent more permanent. See *Rose Industry of Bulgaria*, and Piesse's *Art of Perfumery*.

Pergamus (*per'ga-mus*) or **Per'gamum,** a city of Mysia, in Asia Minor, on the river Caicus, 15 miles from its mouth. According to tradition it was founded by Greeks from Arcadia, but its origin is unimportant. It first acquired prominence when Lysimachus, one of the generals of Alexander the Great, chose it as a stronghold in which to keep his treasures. Under the eunuch Philetærus it became the capital of a state in the year 283 B. C. Attalus III., who died 133 B. C., left it to the Romans, under whom it became one of the chief cities of Asia Minor. It began to decline under the Byzantine emperors, and at the present time, under the name of Bergama, it is noted only for the magnificence of its ruins, which embrace temples, palaces, aqueducts, amphitheatres, besides its city walls. Bergama, 50 miles north of Smyrna, occupies the site of ancient Pergamus. See BERGAMOT, OIL OF.

Peri (*pē'ri*), according to the mystical lore of the east, a being begotten by fallen spirits, which spends its life in all imaginable delights, but is forever excluded from the joys of paradise. It occupies an intermediate place between angels and demons, and is either male or female. Like the fairies in our own popular mythology, the female Peris possess surpassing grace and beauty.

Per'ianth, the general name of the floral leaves of a flower, including both calyx and

corolla. It is more especially used in case the calyx and corolla are similar in appearance, as in the lily.

Per'iblem (in plants). At the apex of the stem or root of the higher plants the great regions are first organized in an embryonic form. The embryonic region which organizes the cortex (which see) is the periblem, and it lies just within the "dermatogen," which is the embryonic epidermis.

Per'icarp (in plants), a name chiefly used in connection with the fruit of seed plants (Spermatophytes), and applied to the transformed ovary, which invests the seeds as a variously modified outer wall. A pea pod, exclusive of the peas, is the pericarp. In apples it is the parchment-like investment of the core; while in the peach the pericarp includes both the flesh and the stone, the "kernel" being the inclosed seed.

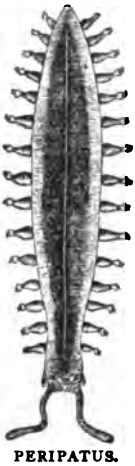
Pericles (*per'i-klēz*), the greatest statesman of ancient Greece, was born in the closing years of the 5th century B. C. He received a thorough and extensive education, but of all his teachers the one whom he always held in the highest regard was the humane philosopher, Anaxagoras. Pericles was noted throughout his public career for the quiet dignity of his manners, the grandeur of his eloquence, his sagacity, his honesty, and his profound patriotism. When he entered public life, although his family did not rank among the highest in wealth or influence, yet so great was his ability and so noble was his character that he soon rose to the highest power in the state as the leader of the popular party. Pericles seems to have grasped very clearly, and to have held very firmly, the modern idea that as the state is supported by the great body of citizens, its laws should be so framed and administered as to secure the greatest good to the greatest number, rather than to promote the interests of any special class or classes. About 463 B. C., Pericles struck a great blow at the Athenian oligarchy by the introduction of a system whereby the poorer classes could serve on juries and take a more active part in public life. Shortly after this, Cimon, the leader of the oligarchy, was banished from Athens by ostracism. By sheer force of his talents and character, Pericles now became the ruler of Athens. In the year 457 B. C., he magnanimously proposed the recall of Cimon, with the agreement between them, it is said, that Cimon should command the army of Athens on its expeditions abroad, and not oppose Pericles in the administration of affairs at home.

PERICLES.

Pericles earnestly sought to unite the various Grecian states in a grand confederation, in order to put an end to all their domestic difficulties and thereby make Greece a powerful nation, able to defend itself against all the powers by which it was surrounded. Had the idea of Pericles been carried out, Athens in later years might have proved herself more than a match for Philip and Alexander of Macedon, and might even have resisted the power of the Roman legions. But there was already that smothered feeling of hostility between Athens and Sparta that rendered the Peloponnesian war inevitable. Pericles warded off this conflict by diplomacy and bribery; but it came at last, in the year 431 B. C. The plague ravaged the city of Athens the next year, and in the year following (429 B. C.) Pericles died, after a lingering fever. It is well nigh impossible to relate all that Pericles did to make Athens the most glorious city in the ancient world. Under his patronage, Greek architecture and sculpture reached their highest development. To him Athens owed the Parthenon, the Odeum, and that most stupendous of all architectural constructions of Greece, the Propylæum. He also encouraged music and the drama; and during his rule industry and commerce were in so flourishing a condition that there was universal prosperity in Attica. Although he had many enemies who denounced him for the expenditure of so much public money upon buildings and amusements, the truthful pen of Thucydides records that he did not act unworthy of his high position, that he never oppressed or persecuted his adversaries, and that although he had unlimited command of the public purse, he was personally above corruption. Plutarch records that when Pericles lay dying and the friends around his bed were reviewing the grand achievements of his life, he quietly interrupted them by saying: "What you praise in my life belongs partly to good fortune, and is, at best, common to me with many others; but the thing of which I am proudest is that no Athenian has ever put on mourning on my account."

Perigynous (*pĕ-rĭj'ĭ-nŭs*) **Flowers,** those in which the sepals, petals, and stamens are borne on the rim of a cup-like body which rises around the pistil or pistils, as in certain members of the rose family. The noun form is perigyny, and the contrasting terms are "hypogyny," in which the other floral parts arise from beneath the ovary, and "epigyny," in which they seem to arise from the summit of the ovary.

Perip'atus, an interesting animal connecting worms and insects. There are about twenty species known, inhabiting South Africa, Australia, New Zealand, South America, and the West Indies. They have a long body like a worm or caterpillar, but the segments, or joints, do not show on the outside. Internally, however, they are well marked. There is no division into thorax and abdomen. The head bears antennæ and jaws. The body is provided with short, jointed feet (14 to 42 pairs), like a thousand-legged worm. Like the myriapods, they are found under stones and in rotting wood, and feed on insects and the like. Their internal structure is noteworthy. They possess a pair of looped tubes in each segment of the body, like those of worms, and, in addition, they have breathing tubes like those of insects and myriapods. There are structural peculiarities of two different sub-kingdoms of animals united in peripatus. It is a sort of generalized form bridging the gap between worms and myriapods, and the myriapods connect with the lowest insects. Peripatus is of much interest to zoologists as a survivor of a very ancient family of animals, and as a link between the worms and arthropods.



PERIPATUS.

Per'isperm, the nutritive tissue which occurs in seeds outside of the embryo-sac. Within the embryo-sac the nutritive tissue is called "endosperm." Perisperm is derived from the nucellus of the ovule, while endosperm is a part of the female gametophyte. In most seeds perisperm does not exist, all the nutritive tissue being endosperm.

Per'istome (in plants), the set of tooth-like processes found at the open mouth of the capsules of mosses. They arise from the rim and extend radially toward the center, and are of various and often beautiful patterns. See MUSCI.

Perpet'ual Motion, stated in modern terms, is a name given to the problem of creating energy. Lavoisier proved the impossibility of creating or annihilating even the most minute portion of *matter*. In like manner, all modern physical investigations have shown the impossibility of creating or annihilating *energy*. And since no mechanism is known which does not absorb some energy in friction, it is evident that if we are to keep any mechanism in motion we must constantly supply it with energy.

This great generalization may be said to date from the year 1847, when Helmholtz published his great memoir on the *Conservation of Energy*. But long before that time, it was well known to clear thinkers that the law of the conservation of energy applied to all purely mechanical operations. Accordingly, in 1775, the French academy declared that it would not thereafter receive any communications upon the subject of perpetual motion. This latter date may, therefore, be considered as marking the complete overthrow of the idea that motion can be secured in any actual mechanical device without a constant supply of energy. And the year 1847 may be considered as marking the overthrow of the idea that perpetual motion can be secured by any means whatever, whether mechanical, electrical, thermal, or otherwise. See articles on ENERGY, and DYNAMICS.

Per'rault (*pā-rō'*), **Charles,** a French author, was born at Paris, Jan. 12, 1628, the youngest of an advocate's four sons. He was sent at nine years of age to the Collège de Beauvais, but quarreled with his teachers, and the rest of his education was left to himself. He studied law and was admitted to practice, but soon tiring of the routine of the legal profession he procured an easy post under his brother, the receiver-general of Paris. Perrault's name has been made immortal by eighteen fairy tales, published in 1697. The titles of these stories are, *The Sleeping Beauty*, *Little Red Riding Hood*, *Bluebeard*, *Puss in Boots*, *The Fairy*, *Cinderella*, *Hop o' My Thumb*, etc. Perrault died at Paris, May 16, 1703.

Per'ry, Oliver Hazard, an American naval officer, was born at South Kingston, R. I., Aug. 23, 1785. He entered the United States navy in 1809, and at the beginning of the War of 1812 was transferred at his own request from the command of a division of gunboats on the Atlantic coast, to serve under Commodore Chauncey on lakes Erie and Ontario. He participated in the attack upon Fort George at the head of a body of seamen, but his fame rests upon the victory he won over the British squadron on Lake Erie, near Put-in-Bay, O., Sept. 10, 1813. In this action, known as "Perry's victory," the Americans were completely victorious, the result being fitly told in Perry's dispatch to the government: "We have met the enemy, and they are ours." He was rewarded with the rank of captain and a vote of thanks by congress. He continued in the naval service of the government throughout this war and for several years thereafter, until his death, which took place at

COMMODORE O. H. PERRY.

Port Spain, on the island of Trinidad, Aug. 23, 1819.

Persepolis (*per-sĕp'ō-lis*) (Persian city), the Greek name for the capital of ancient Persia — the Persian name having been lost. This city was situated in a beautiful plain near the junction of the Araxes (now Bendemir) and the Medus (now Polwar) rivers. Nothing remains of the city at the present day except its magnificent ruins. It was generally designated as the "Glory of the East," and, according to ancient writers, "no other city could be compared with it either in beauty or in wealth." It was not the residence of Cyrus the Great, but Darius Hystaspis, Xerxes, Artaxerxes, and other Persian kings each contributed something to its wealth and glory. It was nearly or wholly destroyed by Alexander the Great in his conquest of Persia, and is scarcely mentioned in history ever afterward. The site of its royal edifices and temples arouses the interest and enthusiasm of every traveler from Chardin down to our own time.

Perseus (*per'sūs*), in Greek mythology the son of Zeus and Danaë. He was brought up on one of the Cyclades, where Polydectes reigned, who, wishing to get rid of him, sent him when yet a youth to bring the head of the Gorgon Medusa. Perseus set forth under the protection of Athena and Hermes, the former of whom gave him a mirror, by which he could see the monster without looking at her (for that would have changed him into stone), and the latter a sickle, while the nymphs provided him with winged sandals and a helmet of Hades or invisible cap. After numerous wonderful adventures he reached the abode of Medusa, who dwelt near Tartessus, on the coast of the ocean, and succeeded in cutting off her head, which he put into a bag and carried off. On his return he visited Ethiopia, where he liberated and married the beautiful Andromeda, who had been fastened to a rock and left as a prey to a terrible sea monster. He then rescued his mother from Polydectes, whom he turned into stone. Perseus was worshiped as a hero in various parts of Greece, and according to Herodotus in Egypt too. In ancient works of art, the figure of Perseus much resembles that of Hermes.

Persia (*per'shi-a*), called by the natives *Irân*, the most extensive and powerful native kingdom of western Asia, is bounded on the north by the Caspian sea and the Asiatic provinces of Russia; on the east by Afghanistan and Beluchistan; on the south by the Indian ocean, the strait of Ormuz, and the Persian gulf; on the west by Asiatic Turkey. It extends about 900 miles from east to west, and 700 miles form north to south, and has an area of 628,000 square miles. It consists for the most part of an elevated plateau, which in the center and on the east side is almost a dead level, but on the northwest and south is covered with mountain chains.

The climate is exceedingly varied. The younger Cyrus is reported to have said to Xenophon that "people perish with cold at one extremity of the country, while they are suffocated with heat at the other." Persia, in fact, may be said to possess three climates — that of the gulf coast, that of the elevated plateau, and that of the Caspian provinces. Along the southern coast the heat of summer and autumn is severe, while in winter and spring the climate is delightful. On the plateau there is considerable difference of climate, and considerable variation from heat to cold. About Ispahan the winters and summers are equally mild; but to the north and northwest of this the winters are severe, and the desert region of the center and east and the country on its border endure oppressive heat in summer and piercing cold in winter. The Caspian provinces in the north, on account of their general depression below the sea level, are exposed to a degree of heat in summer almost equal to that of the West Indies, and their winters are mild. Rains, however, are frequent, and many tracts of low country are unhealthy. Except in the Caspian provinces, the atmosphere of Persia is remarkable for its dryness and purity.

The cultivated portions of Persia, when supplied with moisture, either by rainfall or irrigation, are very fertile — in some places two crops can be raised in the year. The principal products are wheat (the best in the world), barley, corn, sugar, and rice. The vine flourishes in several provinces, and the wines of Shiraz are celebrated in eastern poetry. Opium and tobacco are now among the considerable exports, together with wool, cotton, and the fine Persian hand-made carpets. Pearl fishing is also a growing industry, together with the mining of turquoises and precious stones. The chief ports are on the Caspian sea and the Persian gulf, and the centers of commerce are Tabriz, Teheran, and Ispahan. Persia has now a system of telegraphs and the beginning of a railway system. Mulberries are largely cultivated, and silk is one of the most important productions of the country. The silk cultivation has greatly diminished of late years, however, on account of the silk-worm disease.

Among the domestic animals the horse, the ass, and the camel hold the first place. The horses of Persia are larger and handsomer than those of Arabia, but less fleet. Salt is the principal mineral product, although copper, lead, antimony, and some other minerals abound in certain localities. Considerable coal has been mined in the mountains near Teheran. The settled portion of the population are chiefly descendants of the ancient Persian race with an intermixture of foreign blood. They are all Mohammedans of the Shêa'h sect, except the Sunnis and the few Parsees, who still retain the ancient faith of

Zoroaster. The nomads or pastoral tribes are of four distinct races—Turks, Kurds, Lurs, and Arabs. Of these nomad races the Turkish is the most numerous, the present Kajâr dynasty belonging to it. The nomad races are distinguished for courage, manliness, and independence of character; but they are inveterate robbers, and have been the cause of many revolutions and civil wars. There is a small population of native Christians—the Nestorians of Urumiah and Telmais, and Armenians, whose principal settlement is at Ispahan. Including those who have joined the Roman Catholic and Protestant churches, the whole number of Christians can hardly exceed 50,000. Christian missions are, however, making steady progress in Persia. The population of Persia is variously estimated at from 9,000,000 to 10,000,000. The chief cities are Teheran, the capital (population 250,000), Tabriz (population 180,000), and Ispahan (population 80,000). The government is a pure despotism, the "shah," or "padishah," possessing absolute authority over the lives and property of his subjects. His deputies, the governors of provinces and districts, possess a like authority over those under them, although they are accountable to the shah, and may be punished by him for any acts that he does not approve. The revenue is derived almost exclusively from a tax on the land and its products, and as a natural result the peasantry are seriously oppressed by the provincial governors. It is believed that great as the legal taxes are, the illegal exactions amount to nearly an equal sum. For the history of ancient Persia, see CYRUS THE GREAT, DARIUS, XERXES; also Rawlinson's *The Seventh Great Oriental Monarchy*.

Per'sian Gulf, an arm of the Indian ocean, lying between Arabia and Persia. Its length is 600 miles, its breadth varying from 50 to 250 miles. Total area, about 75,000 square miles. The order of the periodic currents in this gulf is precisely the reverse of those of the Red sea, as they ascend from May to October, and descend from October to May. The greatest depth of the Persian gulf does not exceed 50 fathoms. Oriental geographers give to this gulf the name of the "Green sea," from the strip of water of a greenish color lying along the Arabian coast.

Persigny (*per-sēn-yē'*), **Jean Gilbert Victor Fialin,** an adherent of Napoleon III., was born at Saint-Germain l'Espinasse, Jan. 11, 1808. He entered the cavalry school at Saumur in 1826, and the 4th Hussars in 1828, but was expelled from the army for insubordination in 1831. In 1834, he became acquainted with Louis Napoleon, and established a journal devoted to the advocacy of Bonapartist principles. He had the chief hand in the affair of Strasburg, in 1836; and in 1840, he participated in the descent on Boulogne, for which he was sentenced to 20 years' imprisonment. Persigny was very active in securing the election of Louis Napoleon as president of the republic in 1848; and he also took a prominent part in the *coup d etat* of December, 1851. He filled various offices under Napoleon III., until 1853, when he was created duke. He then sat in the senate until the fall of the empire in 1870. He died at Nice, Jan. 12, 1872.

Persim'mon, a tree from thirty to sixty feet in height, which yields a fruit about the size of a plum, with six to eight oval seeds. It is very astringent until over-ripe and mellowed by frost, when it has a sweet and agreeable taste. It is a native of the southern portions of North America, where one tree often yields several bushels of fruit.

Persius (*per'shi-us*), **Aulus Flaccus,** a Roman satirist and poet, was born in Etruria, Dec. 4, 34 A. D. He was educated in his native town, but in early manhood went to Rome, where he received instruction from the Stoic philosopher Cornutus, who imbued his mind with the tenets of that school and exerted a marked influence upon his life and character. Persius died in the year 62, when twenty-eight years old, and was distinguished in a marked degree for the purity and integrity of his character. He left at his death six brief satires, the whole not exceeding 650 hexameters; but these have been held in high esteem down to our own day, fathers of the church, like Augustine and Jerome, and humanists, like Buchanan and Casaubon, finding employment in interpreting the poet's ridicule of the degeneracy of his times. "Probably no writer ever borrowed so much and yet left on the mind so decided an impression of originality," says Covington, who further indicates the resemblance between the genius of Persius and that of Carlyle.

Perth Am'boy', N. J., a city and port of entry in Middlesex county, situated at the mouth of Raritan river, where it falls into Raritan bay, at the foot of Staten Island sound, 20 miles south of New York city. It is reached from the latter by a number of railroads, chiefly by the Central of New Jersey, the Pennsylvania, and Lehigh Valley railroads. Deposits of kaolin and fire-clay are found in the city, and give employment to terra-cotta, drain-tile, and fire and glazed brick works, etc. There are also machine-shops; iron foundries; chemical, emery, and cork works; oil-refineries, together with the large coal and freight wharves of the Lehigh Valley railroad, abutting on the fine harbor. There are good schools, churches, banks, and other civic equipments. Population 17,699.

Perth, a city of Scotland, on the right bank of the Tay, 43 miles from Edinburgh and 62 miles from Glasgow. The great beauty of its surroundings—the noble river, the two wooded heights, Moncreiff and Kinnoul hills, each 700 feet high, and away to the north, the Grampians—makes the "Fair City" well worthy the name. A handsome bridge of nine

arches connects the city with the suburb of Bridgend, where Ruskin spent a portion of his childhood. Along the bank of the Tay extend two beautiful public parks, each containing nearly 100 acres.

The *Five Articles of Perth*, memorable in the ecclesiastical history of Scotland, were agreed upon in a meeting of the general assembly, by command of James VI., in 1618. They enjoined kneeling at the Lord's Supper, the observance of Christmas, Good Friday, Easter, and Pentecost, and sanctioned the private administration of baptism and the Lord's Supper. These articles became one of the chief subjects of that contention between the king and the people which produced such serious results in the succeeding reign of Charles I. The general assembly of Glasgow in 1638 declared that of Perth to have been "unfree, unlawful, and null," and condemned the five articles. The population of Perth in 1900 was 30,820.

Peru, a republic of South America, bounded on the north by Ecuador, on the east by Brazil and Bolivia, on the south by Chile and the Pacific ocean, and on the west by the Pacific. Its area is not definitely known, but may be estimated at about 695,733 square miles. The population, not including wild Indians, according to a census made in 1896, was 4,609,999, the aboriginal Inca Indians constituting over fifty per cent. of this number. The length of Peru along the Pacific coast is nearly 1,500 miles; its breadth at its northern boundary is between 700 and 800 miles, while at the southern boundary it is less than 100 miles. The surface of Peru is divided into three distinct tracts, the climate of which varies from torrid heat to arctic cold, and whose productions range from the stunted herbage of the mountain slopes to the rich fruits of the tropical valleys. These three separate regions are the Coast, the Sierra, and the Montaña. The Coast is a strip of land from 30 to 60 miles in width, extending from the western Cordillera to the Pacific ocean. It is for the most part a sandy desert, but it contains many fertile valleys watered by streams that have their sources on the slopes of the Cordilleras. Between these valleys are trackless deserts of greater or less width, covered with a shifting, yellow sand, which is often carried about by the wind in pillars 100 feet high. In the Coast region, rain is unknown. This is due to the fact that the southeast trade winds of the Atlantic, after traversing the continent from its eastern coast, exhaust their remaining moisture in covering the Cordilleras with snow, after which they fall upon the western coast of Peru cool and dry. The Sierra embraces all the region between the eastern and western Cordilleras and the two ranges of the Andes. This region averages 100 miles in width, and has been estimated to contain an area of 150,000 to 200,000 square miles. After the tablelands of Thibet, those of Peru are the highest in the world. Unlike those of Thibet, which are mere grassy uplands, they are studded with towns and villages; and even at this elevation the climate is pleasant, and wheat, corn, barley, rye, and potatoes are produced in no insignificant quantities. At the height of 9,000 feet above the sea level, the mean temperature is 60° Fahrenheit, and the variation throughout the year is not great. The soil of the Sierras is of great variety, but is generally fertile.

The Montaña region extends eastward from the Andes to Brazil and Bolivia. It embraces more than half the area of Peru, and almost its only inhabitants are a few scattered tribes of Indians. It consists of vast forests and alluvial plains, is rich in all the productions of tropical latitudes, and teems with vegetable and animal life. The wealth of Peru consists entirely in mineral, vegetable, and animal products. The chief exports are cotton, coffee, and sugar. Maize, cocoa, rice, and tobacco are also among the exports. Wood, alpaca, and rubber are with guano exported products, together with bar silver, gold, copper, and lead. The Andes abound in gold, silver, copper, lead, etc.; and in the Montaña region, gold is said to exist in abundance in veins and in pools on the margins of rivers. The public revenue is derived mainly from the sale of guano, and only to a small extent from customs.

Peru was under the dominion of Spain from the time of its conquest by Pizarro in the 16th century until the year 1821, when it was proclaimed an independent republic under the protectorate of General San Martin, one of the liberators of Chile. San Martin retired on the arrival of Gen. Simon Bolivar in 1823, and the next year occurred the battle of Ayacucho, in which the Spanish viceroy was taken prisoner, and the Spanish dominion finally came to an end. Bolivar left Peru two years later, but it was not until 1844 that the government was fully settled under the presidency of Ramon Castilla. In 1879, Peru, as the ally of Bolivia, became involved in a war with Chile, the latter state coveting the nitrate deposits in the Peruvian province of Tarapacà. This war was disastrous to Peru on both land and sea, the provinces of Tacna and Tarapacà being wrested from her, and in 1881 the Chilean army entered Lima, the capital. Peace was concluded in October, 1883, and some months afterward the Chileans evacuated the country. Under the presidency of General Càceres and his successor, Col. Don Remijio Morales Bermudez, Peru made slow but certain progress in repairing the wastes and losses that she suffered during her conflict with Chile.

Perugia (*pā-rō'jā*), a city of Italy, stands on the right bank of the Tiber, 1,700 feet above the level of the sea, ten miles east of the lake of Perugia, and 125 miles by rail

from Rome. It is surrounded by walls pierced with numerous gates, of which the Etruscan arch of Augustus is the finest. The university (founded in 1276) has 26 teachers and 320 students, a botanical garden, an observatory, a valuable antiquarian museum, and a library of 40,000 volumes. Perugia became a part of the kingdom of Italy in 1860, and has a population of 61,292.

Perugino (*pā-rū-jē'nō*), a celebrated Italian painter, whose real name was Pietro Vannucci, was born in Umbria in 1446, but as he established himself in the neighboring city of Perugia, he has generally been given the name of Perugino. At Rome, to which place he went in 1483, Pope Sixtus IV. employed him in the Sistine chapel; his fresco, *Christ giving the Keys to Peter*, is the best of those still visible — others being destroyed by him to make way for Michael Angelo's *Last Judgment*. He returned to Perugia in 1512 and painted a number of pictures there. He was engaged in painting frescos in a church near Perugia in 1524, when he was seized with the plague, of which he died.

Pessimism (*pes'sim-ism*), is the theory or doctrine that on the whole the world is bad rather than good; or, it might be defined as the negative answer to the question, "Is life worth living?" Pessimism in its hold upon so many minds may be referred to the contemplation of actual pain and unhappiness in the world, and also to the fact that the actual world is so far inferior to the ideals of the human soul that we can never be satisfied with things as they are, or even with the progress mankind is making toward a higher and better condition. Pessimism as a mood or temper of mind has existed in all ages of the world, but it is only in recent times that it has been elaborated into a complete philosophy or theory in the systems of Schopenhaur and his successor, E. von Hartmann. The full force of pessimism lies in the assertion that all the ends and aims of life are illusory, that life brings only illusions, the chief illusion of all being man's belief that he is born to enjoy life. According to the pessimistic theory, nothing of value is ever attained in this world, as its very essence consists in strife and change, and in the case of the individual life there is an excess of unhappiness and pain over happiness and pleasure. To the first of these statements, that nothing of value can be attained in this world, it may be answered that it is not rational to despise the realization of certain ends because there arise other ends to be realized. It is natural and therefore rational for the infant to enjoy its first walk across the floor even though it has all the lessons of life yet to learn. The assertion that in the individual life there is more pain than pleasure is disproved by our consciousness and our experience. We desire to live, therefore our lives must be worth living, at least to ourselves. But whatever errors may be found in pessimism, it certainly involves the truth that happiness is not to be obtained by direct seeking, and that life can be made valuable only by losing sight of self and directing our thoughts and energies to high and noble purposes without ourselves; or, to express the same principle in scriptural phrase, "He that loseth his life shall find it."

Pestalozzi (*pes-tä-lot'sē*), **Johann Heinrich,** a Swiss educational reformer and founder of modern pedagogy, was born at Zurich, Jan. 12, 1746. Eager to be an adjuster of social wrongs from his youth, he sought to realize his aims through the education of the young, and to him belongs the high honor of conceiving a method which is the corner stone of all sound theories of education, especially of primary education. Although he was illiterate, ill-dressed, a poor speaker, and a poor manager, and although all his undertakings resulted in practical failure, he yet aroused the admiration of Europe, and called forth a host of disciples, who down to the present day have carried out the principles of their master with the greatest enthusiasm. Pestalozzi was totally unable to cope with the world, but he awoke the minds of men to a sense of their responsibility to childhood, and ushered in the 19th century as the educational age *par excellence*. He first sought to carry out his theories by collecting a number of orphans and outcast children upon a farm in the canton of Aargau to educate them by a blending of industrial, mental, and moral training; but on account of a faulty domestic economy this enterprise failed, and was abandoned after a five years' struggle. Soon after this he published his *Evening Hours of a Hermit*. In this work he developed the following principles as the basis of education: In educating man, seek first of all to *know* him; the method whereby to educate anyone should be founded upon his own nature; in his nature are hidden the forces that will draw out his faculties, therefore exercise them; it is exercise that connects the wants of our nature with the objects that satisfy those wants, and everyone's education should answer to his own needs and the inner call of his or her soul. In later years, Pestalozzi published his work *How Gertrude Educates Her Children*, which is the recognized exposition of the Pestalozzian method, and sets forth that the education and development of human nature should be in harmony with natural laws; that in order to teach well, we should study the processes of nature in man and its particular processes in individuals, and that *observation*, which is a spontaneous perception of things, is the method by which all objects of knowledge are brought home to us. This last affirmation contains the essence of the whole theory of institutional education. In 1805, Pestalozzi moved his school from Berthond to Yverdon, which drew upon him the eyes of all Europe; but the same incapacity in practical affairs that had caused the failure of all his other

schemes showed itself here, and in 1825 this school was closed, and Pestalozzi withdrew to Brugg, where he lived an object of mingled pity and respect until his death, which took place Feb. 17, 1827.

Pesth, or rather Budapest, the capital of Hungary, and next to Vienna, the second city in the Austro-Hungarian empire. Pesth stands on the left bank and Buda on the right bank of the Danube, 170 miles from Vienna, and since 1873 the two cities have been united in one municipality. The two towns are connected by chain bridges and a railway bridge. Buda is much the older town, Pesth being an essentially modern place — the growth of the 19th century principally. It has many fine streets and squares, and the buildings are noted for their large size and substantial appearance. Among them may be mentioned the Jewish synagogue, the parish church, the national museum, the parliament house, etc. While Pesth stands on a plain, Buda is built on small, steep hills, and is backed by vine-clad slopes. Population of both towns in 1890, 505,763. See BUDAPEST.

Pet'als, the individual parts of the corolla, or inner set of floral leaves. The petals are usually the showy members of a flower, their size, delicacy of texture, and color giving it its character. See FLOWER.

Petard (*pē-tärd'*), an instrument for blowing open the gates of a fortress, demolishing palisades, etc. It consisted of an iron or wooden case filled with powder and ball; this was firmly fastened to a plank provided with hooks, by which it was securely attached to a gate. The petard, which was lighted by a slow match, has been superseded by powder bags.

Pe'ter, St., one of the twelve apostles of Jesus, was born at Bethsaida, on the sea of Galilee, but during the public ministry of Jesus, had his home at Capernaum, where he appears to have lived with his brother Andrew. His original name was Simon, to which Jesus added Cephas, from the Syriac *kepha*, "a rock," the Greek word for the same meaning *petra*, whence Peter. He was a fisherman, and was engaged in his daily work when Jesus called both him and Andrew to be his disciples, promising to make them "fishers of men." Peter was undoubtedly regarded by Jesus with special favor and affection. In many respects he was an ideal disciple, warmly attached to his master, and ardent, fearless, and energetic in the service of the cause he had espoused. It is not without reason, therefore, that Matthew heads his list of apostles with "the first, Simon, which is called Peter." This position of leadership among the apostles Peter continued to hold. Peter was the first mover in the election of a new apostle in place of Judas Iscariot; he was the spokesman of the other apostles on the day of Pentecost, and when they were brought before the council, he was the judge who condemned Ananias and Sapphira, and he was the first apostle to baptize a Gentile convert.

Peter took an active part in the apostles' council or conference in Jerusalem, and at Antioch he labored in harmony with Paul for a time, but afterward arose the famous dispute between them, in which Paul says "he was to be blamed" for separating himself from the Gentile converts, and refusing longer to eat with them, lest he might give offense to certain Jewish converts. The history of Peter from this time rests mainly on tradition. It is generally believed that after remaining in Antioch for some time — according to Jerome and Eusebius, he was bishop there for several years — his missionary labors extended to Pontus, Cappadocia, Galatia, and Bithynia and, some have thought, even to Babylon. It is now generally conceded that he paid one or more visits to Rome, and that he suffered martyrdom there. Tradition records that Peter was crucified with his head downward, he himself requesting this, as he was not worthy to be crucified in the same position as his Lord and master.

Pe'ter the Great (Peter I., Alexeievitch, emperor of Russia), was born at Moscow, June 11, 1672. His father died in 1676, leaving the kingdom to his eldest son, Feodor, Peter's half-brother. Feodor died in 1682, without issue, after naming Peter as his successor, to the exclusion of his own full brother, Ivan, who was weak-minded. This, however, provoked an insurrection of the "strelzi," or militia, under the leadership of Ivan's sister, the grand duchess, Sophia, who thereby succeeded in obtaining the coronation of Ivan and Peter as joint rulers, with herself as regent. Immediately after his coronation Peter was placed under the instruction of François Lefort, a native of Geneva, who taught him the various arts and sciences of civilization, and showed him how far Russia was behind other European nations in all these. In the year 1689, Peter called upon his sister Sophia to resign her position as regent, which she refused to do; but after a severe contest, she was compelled to yield, and was shut up in a convent, where she remained until her death, in 1704. Ivan abdicated his share of the government in 1696.

PETER THE GREAT.

Peter's first care in assuming the government was to reorganize his army, in which he was greatly assisted by Gordon and Lefort,

both military men. He also labored to create a navy, and to this end invited skilled engineers and architects from other countries to assist in the construction of his ships; and he himself went to sea on board English and Dutch vessels that he might acquire the art of navigation. Many of the young nobility were ordered to travel in Holland and Italy, to take special notice of all matters in connection with shipbuilding and naval equipment; others were sent to Germany to study the military art. In 1697, Peter set out on his famous tour or visit to foreign countries, and worked for some time as a ship carpenter at Zaandam, in the Netherlands, and to his knowledge of shipbuilding and other trades added the study of astronomy, natural philosophy, geography, and even anatomy and surgery. On the invitation of William III., he visited England and for three months, partly in London and partly in Deptford, labored to acquire all kinds of useful information. He returned to Russia in 1698, taking with him five hundred English engineers, artisans, etc., and immediately proceeded to the execution of various reforms in his government. Among others was the introduction of arithmetic, which was unknown in Russia up to this time, accounts having been previously kept by means of the abacus, an instrument consisting of a frame with a number of parallel wires on which beads or counters are strung. Trade with foreign countries was not only permitted but insisted upon. Many changes in manners and dress were also prescribed and enforced on the people, and the czar's reforming zeal even extended to the national church.

On May 27, 1703, Peter laid the foundation of the new capital of Russia, St. Petersburg, being at the time engaged in a bitter war with Charles XII. of Sweden. In this long contest, the Russians were nearly always defeated, but at the battle of Pultowa, July 8, 1709, Charles' forces were completely routed, and Peter took possession of the Baltic provinces and a portion of Finland in the next year. In 1712, his marriage with his mistress Catharine was celebrated at St. Petersburg, and all the offices of the central government were transferred to the new capital. In company with the czarina, he made another tour of Europe in 1716–17, this time visiting Paris and carrying home with him quantities of books, paintings, statues, etc. Soon after this his son, Alexei, who had opposed some of his father's reforms, was condemned to death and died in prison. Many nobles implicated in his treasonable plans were punished. After concluding peace with Sweden, in 1721, Peter made war upon Persia, in order to open the Caspian sea to Russian commerce, by which he secured three Caspian provinces and the towns of Derbend and Baku. The last years of his life were chiefly employed in improving his capital and carrying out his plans for the diffusion of education among his subjects. He died at St. Petersburg, Feb. 8, 1725, and was succeeded by his empress, under the title of Catharine I.

Pe'ter II. (of Russia), the sole male representative of Peter the Great, being the son of the unfortunate Alexei (see above), was born at St. Petersburg, Oct. 23, 1715. On the death of the czarina, Catharine I., he ascended the throne, in 1727, but after a reign of a little over two years, died of the small-pox, Jan. 29, 1730.

Pe'ter III. (Feodorovitch, of Russia), grandson of Peter the Great, being the son of his eldest daughter, Anna Petrowna, was born at Kiel, Jan. 29, 1728, and in 1742 was declared by the czarina Elizabeth her successor on the throne of Russia. Peter succeeded Elizabeth, on her death in 1762, and his first act of authority was to restore East Prussia to Frederick the Great, whom he greatly admired, and to send to his aid a force of 15,000 men. He also recalled a great many political exiles from Siberia. While he was arranging a campaign to take Sleswick from Denmark, soon after his inauguration, an insurrection, headed by his wife and the principal nobles, broke out against him in St. Petersburg, a conspiracy which originated in the discontent over his liberal policy, his preference for the Germans, his indifference to the national religion, and his servility to Frederick the Great. The result of this conspiracy was that Peter was declared to have forfeited his crown, and was soon after strangled in his bed, in 1762, by Orloff and other conspirators. He was succeeded by his wife as Catharine II.

Pe'ter the Her'mit, the apostle of the first crusade for the recovery of Jerusalem from the Mohammedans, was born at Amiens, France, about the year 1050. After serving some time as a soldier he became a monk, and is said to have made a pilgrimage to the Holy Land before the year 1094, when he began the preaching campaign which started so many thousands on the famous march to Jerusalem. A portion of the first crusade army was led by Peter himself, but at the siege of Antioch he attempted to desert, and, when several miles on his way home, was brought back by the soldiers of Tancred to receive a public reprimand. When Jerusalem was taken by the crusaders, the next year, Peter preached a sermon to them on the Mount of Olives. At the end of the crusade, he returned to Europe and founded a monastery at Huy, in Belgium, where he died July 11, 1115.

Pe'ters, Christian Henry Friedrich, a highly-distinguished American astronomer, was born at Koldenbüttel, Germany, Sept. 19, 1813. After completing his course at the University of Berlin, he traveled for several years in Palestine and other countries in the east. He then came to the United States,

and after serving in the coast survey, was elected professor of astronomy at Hamilton college, New York, in 1858. In 1859, he determined accurately the longitude of his observatory, as well as that of other places in the state of New York, and of the observatory of Ann Arbor, Mich. Professor Peters took part in the observation of the solar eclipse of Aug. 7, 1869, at Des Moines, Ia., and was at the head of the party sent by the United States government to New Zealand to observe the transit of the planet Venus, which took place Dec. 9, 1874. His party obtained over 200 photographs of the transit, and he was able to measure the apparent diameter of the planet, thus determining its size more nearly than had ever been done before. He died at Clinton, N. Y., July 18, 1890.

Pe'tersburg, the third city of Virginia, on the left bank of the Appomattox river, 23 miles by rail south of Richmond. The falls above the city furnish water-power for foundries, cotton, flour and paper mills, and tobacco factories. The "Siege of Petersburg," which lasted ten months, was an important chapter in General Grant's campaign against Richmond in 1864. Although attacked several times, it did not fall until it was evacuated by the Confederate forces in the spring of 1865. Population 21,810.

Pe'ter's Pence, a name of a **tax**, for the benefit of the pope, in memory of St. Peter. Its origin has been ascribed by some to Ina, king of Wessex, by some to Offa of Mercia, and by others to Alfred the Great. It consisted in the payment of a silver penny, by every family possessing land or cattle of the yearly value of 30 pence. The tax, also called Rome-scot, varied in amount, and continued to be paid until the Reformation. The pope having suffered a great loss of revenue by the revolution of 1848, efforts have been made since that time to revive the payment of Peter's Pence, not as a tax, but by the collection of freewill offerings. In some countries this has been largely successful; and since the annexation of the papal states to the kingdom of Italy, the fund has been largely increased. On the occasion of the jubilee of Pius IX., in 1877, the payment amounted to $3,000,000.

Pet'iole, the stalk-like portion of a leaf, as distinguished from the blade. Leaves without petioles are said to be "sessile." See LEAF.

Petiolule (*pĕt'ĭ-ō-lūl*), in compound leaves the stalk-like portion of a leaflet, as distinguished from the general stalk or petiole of the whole leaf.

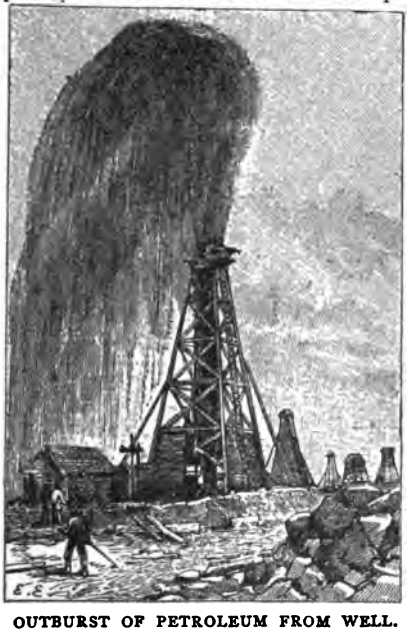
Petrarch (*pĕ'trärk*), **Frances'co,** one of the earliest and greatest of modern lyric poets, was born at Arezzo, Italy, July 20, 1304, his parents being exiled from Florence at the time. The poet's infancy was passed in Tuscany, until 1312, when his father determined to go to Avignon, whither the papal court had been transferred. There his studies began, and were continued later at Montpellier and Bologna. His father intended him for the legal profession, but instead of the law, he devoted himself to the study of the Latin classics, the two authors on whose style he strove to model his own being Cicero and Virgil. After his father's death, Petrarch returned to Avignon, and having lost a large portion of his patrimony, qualified himself for ecclesiastical preferment, but never took holy orders. It was in this early period of his life that he first saw Laura, whose name he has immortalized in his lyrics, and who inspired him with a passion which, although unrequited, has become proverbial for its constancy and purity. The identity of Laura has been a subject of considerable discussion, but the most generally-accepted theory is that of the Abbé de Sade, who identifies her as Laure de Noves, the wife of Hugo de Sade, and the mother of eleven children. The fame of Petrarch's learning and genius was such that he received the highest consideration from all the rulers and the learned men of his age; but the most glorious day of his life was when he was crowned poet-laureate by the senate of Rome on Easter Sunday, 1341. After the death of his beloved Laura, and his friend, Cardinal Colonna, he left Avignon, disgusted with the vices and corruptions of the court. The remaining years of his life were passed in various towns of northern Italy, and in his country house near Padua, where, tenderly cared for by his natural daughter, Francesca, and her husband, and occupied to the last in his favorite studies, he died, July 18, 1374. See Henry Reeve's little book on Petrarch.

Pet'rel, the name for small sea birds often seen flying over the ocean. They are commonly called Mother Carey's chickens by the sailors. There are two kinds seen in the North Atlantic — Wilson's petrel and Leach's. The former nests in the southern hemisphere in February, and comes north in May. It is the form most frequently seen in crossing the Atlantic. They follow the ship for food thrown overboard. Leach's petrel nests on our coast from Maine northward. Both these birds are small, being about seven and one-half inches long. They are black with a white spot on the upper side at the base of the tail. In all, there are about seventy species of petrels. Several inhabit the southern seas, and the group includes the giant fulmar, about the size of one of the smaller albatrosses. The name petrel is a diminutive of Peter, and refers to the appearance they present of walking on the water.

Pe'trie, William M. F., an English author and explorer, was born at Charlton, England, June 3, 1853. Having been educated privately, he early devoted himself to a study of ancient British earthworks, but in 1880 turned his attention to the Nile valley, where he has

practically been ever since, although holding a professorship in the University college, London, in the department of Egyptology. He discovered the Greek settlements at Naukratis and Daphnæ; the prehistoric Egyptian settlement at Koptos, and the home of a new race at Nagada. He published an inscription of the Israelite war at Thebes. During the 20 years he has been at work in Egypt, he has published no less than 21 volumes bearing upon the life and history of the ancient Egyptians. Perhaps that which attracted the most attention throughout the whole world of scholars was the report of his work at Tel-el-Amarna, a modern Arab village on the east side of the Nile, midway between ancient Thebes and Memphis, where Amenophis IV., the "heretic" king, built his royal residence about 1500 B. C. A great many tablets in cuneiform characters were here found, which are now in the museums of London, Berlin, and Cairo. These are mostly reports from the east, and contain many names known to Bible students.

Petro'leum, a fluid form of bitumen, also known as mineral oil, rock oil, etc. In nature it occurs principally in the pores of porous rock. It is extracted from the rock through wells, the same as water. The origin of petroleum has been much discussed, and the general belief is that it represents a distillation product of organic matter which was buried in the sediments when they accumulated. It is quite probable that both animal and plant



OUTBURST OF PETROLEUM FROM WELL.

matter have contributed to the production of petroleum. In the case of profitable petroleum wells, the porous layer containing the petroleum is usually covered by a relatively impervious layer, which prevents the oil from escaping upward. When the well boring penetrates this impervious layer, the oil has a chance to escape. It sometimes spouts up with great force, like the water in flowing wells. In other cases, it has to be pumped out. A well which flows when it is first made, often ceases to flow at a later time, and the oil then has to be pumped out. Still later, it may cease altogether to yield oil, because the reservoir (the porous rock) from which it drew its supply, is exhausted. The average length of life of an oil well is but a few years. The yield from wells is very variable, some of them yielding but a few barrels a day, while others yield hundreds, or even thousands, of barrels a day. Such extraordinary flows are usually of short duration.

Petroleum is found in various parts of the world. The following table shows the sources of the larger part of the product for the United States in 1898: —

	BARRELS.
Ohio	18,738,708
Pennsylvania	14,743,214
West Virginia	13,615,101
Indiana	3,730,907
California	2,257,207
New York	1,205,250
Texas	546,383
Colorado	444,070
Kansas	71,980

Recently (1901) extensive finds of petroleum have been made in southeastern Texas, near Beaumont. This oil field is yet but slightly developed, but appears to be most promising. The wells here are less than 1,000 feet in depth. That is about the same as the shallower wells of southeastern Ohio and West Virginia. The oil flows from some of these wells under tremendous pressure. It is estimated that in one case it was shot up into the air as high as 600 feet, and that for a time the flow amounted to as much as 1,000 barrels an hour. (See *Engineering and Mining Journal*, Jan. 26, 1901).

Petroleum occurs in formations of various ages. That of western Ohio, Indiana, Michigan, and Canada occurs in rocks of the Ordovician system; that of Tennessee and Kentucky, in the Silurian; that of New York and Pennsylvania, in the Devonian; that of West Virginia and eastern Ohio, in the Lower Carboniferous; that of Kansas, in the Carboniferous; that of Texas and the Western States, in the Cretaceous and Tertiary formations. The petroleum, as it is derived from the wells, is crude, and is subjected to refining processes before it is put on the market.

See Orton: *Geology of Ohio*, Vol. VII.; *U. S. Geological Survey*, 8th Annual Report, Part I.; *Bulletin of the Geological Society of America*, Vol. I.

Pet'tie, John, a Scottish artist, was born at East Linton, near Haddington, in 1839, and early became a student of art in the Scottish academy. His first exhibited pictures were *The Prison Pet*, at Edinburgh in

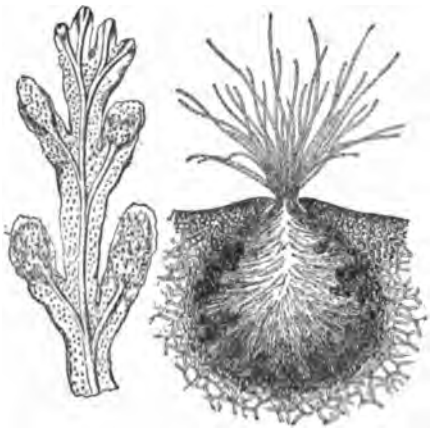
1859, and *The Armorers* at the Royal academy in 1860. But the first work which showed the high qualities of his genius was *A Drumhead Court-Martial*. He died at Hastings, Feb. 21, 1893.

Pet'ty Officers in the navy correspond to non-commissioned officers in the army.

Pe'wee (or Wood-pewee), a small fly-catcher sometimes confused with the phœbe. It is smaller than the latter, being about six and one-half inches long. It is dark olive-green above and whitish below, washed with dusky. The under bill is yellow. It is a gentle forest bird, with a plaintive note of *pe-wee-ee*. See PHŒBE.

Phædrus (*fē'drus*), translator of Æsop's "Fables" from Greek into Latin verse. While still young he came to Italy, and in Rome or some other city studied Ennius, whom he quotes in the epilogue to his third book. From the title of this book he appears to have been first the slave and afterward the freedman of Augustus Cæsar. Although Phædrus only claimed to be a translator of Æsop, he was more than that; he wrote fables of his own, using the name of Æsop to recommend his verses. Phædrus lived in the early part of the first century A. D.

Phæophyceæ (*fē-o-fī'sē-ē*), plants forming one of the great groups of algæ, commonly known as the brown algæ or "kelps." They are almost all marine, and



FUCUS OR ROCKWEED.

The figure to the right shows the receptacle which contains the sex organs.

are very characteristic forms of the coast. They are all anchored forms, their floating olive green, yellow, or brown bodies usually being buoyed up by floats or air-bladders. The largest kelps are in the colder waters, and are also called "wrack," "tangle," "dangle," etc.

Some of them are filamentous forms, but others are very much more complex. The species of Laminaria are like huge floating and rooted leaves, frequently nine to ten feet long. The largest known Laminaria is an Antarctic form, which rises to the surface from a sloping bottom, with a floating leaf-like body 600 to 900 feet long. Other forms rise from the sea-bottom like trees, with thick trunks, numerous branches, and leaf-like appendages. One of the most common forms is the "rockweed" or fucus, whose forking body is full of swollen air-bladders. The noted Sargassum or "gulf weed" is a member of this group. It is often torn from its anchorage by the waves and carried away from the coast by currents, collecting in the great sea eddies produced by oceanic currents, and forming the so-called "Sargasso seas," as that of the North Atlantic.

Phaethon (*fā'e-thon*), "the shining one" in the writings of Homer and Hesiod, a frequent title of Helios, the sun-god. In Greek mythology Phaethon is also the name of a son of Helios, famous for his unfortunate attempt to drive his father's chariot. Scarcely had the presumptuous youth seized the reins when the horses, perceiving his weakness, ran off, and approaching too near the earth, almost set it on fire. The earth then called upon Jupiter for help, and he struck down Phaethon with a thunderbolt. His sisters, who had harnessed the horses of the sun for him were changed into poplars and their tears into amber.

Phal'anx, the ancient Greek formation for heavy infantry, was a series of parallel columns standing close one behind the other. The oldest phalanx was the Spartan, in which the soldiers stood four, six, or more, generally eight, deep. The Macedonian phalanx was sixteen men deep. The heavy-armed phalanx was ordinarily flanked by *peltastes*, or light infantry, who usually fought with javelins and slings.

Phanerogams (*făn'er-ō-gămz*), a name commonly applied to the spermatophytes or seed plants, but now passing into disuse. It was given in contrast to cryptogams (which see), and means that the sexual reproduction is evident, the stamens and pistils being mistaken for sexual organs. See SPERMATOPHYTES.

Pharaoh (*fā'rō* or *fā'ra-ō*), the name or title given in the Bible to the monarchs of Egypt. Although the term is only an official title, it is generally used as if it were a proper name; and there has been great difficulty in determining the particular monarchs who pass under this name in the Old Testament.

Phar'isees, a Jewish sect or school distinguished for their devotion to the Law and their rigid observance of all the rites and ceremonies of the Jewish church. The name of Pharisees—from *perûshim*, "separated"—was probably at first bestowed upon them in derision by the Sadducees, the priestly

aristocracy, who differed from them politically, and to some extent, religiously. The Pharisees believed in future immortality, while the Sadducees held that there was nothing in the Scriptures to warrant it. Also the Pharisees held all the traditional ordinances in equal reverence with the Mosaic institution, while the Sadducees rejected many traditional observances or varied them according to the traditions of their own families. In general, the Pharisees administered justice in a much milder manner than the Sadducees, as the latter took their stand upon the strict letter and would hear of no mercy when the code was clearly violated. Out of the Pharisees arose the great doctors and teachers of the law, usually termed "Scribes," and to them the most important offices were intrusted by later rulers. That the Pharisees as a body were actuated by a sincere and patriotic purpose to preserve the religion of their fathers from corruption and foreign contamination must be admitted; but it is also very clear that in their intense devotion to the letter of the law and the traditions of the elders, they lost sight of its spirit, and were therefore wholly unprepared for the coming of that Messiah whose kingdom was a spiritual kingdom, and who said to his disciples: "The words that I speak unto you, they are spirit, and they are life."

Pheas'ant, a long-tailed game bird, related to the partridge. There are about forty species of pheasants, mostly large birds, with brilliant colors, showing metallic luster. Among their colors are gold, copper, scarlet,

PHEASANT.

green, and blue. They are mostly natives of Asia and live in dense woods. The so-called English pheasant was naturalized in Great Britain before the Norman conquest, and is bred in the game preserves of Europe. It has also been introduced into the United States. The male has metallic tints of blue and green on the breast. It is about three feet long, including the tail, which represents one-half the length. The copper pheasant of Japan, and the ringed-neck pheasant of China, have been introduced into western Oregon. The pheasants of China, Thibet, India, and islands of the Malay archipelago are often very gorgeous in plumage. The golden pheasant of China and Thibet is very striking, being mostly golden above, and scarlet below, with a ruff of orange and black. The silver pheasant is silvery white above, penciled with black. Both these birds have been introduced into Europe. The tail is sometimes very long, for example, in Reeve's pheasant of China, it is five and one-half feet long. This bird is found in the game preserves of Europe. The ruffed grouse of North America is incorrectly called pheasant. See Elliot's *A Monograph of the Phasianidæ;* Tegetmeier's *Pheasants: their Natural History and Management.*

Phelps, Edward J., an American jurist and diplomat, was born at Middlebury, Vt., July 11, 1822; educated at Middlebury college, and graduated in law at Yale in 1843. He was admitted to the bar at his old home in the same year. In 1851, he was appointed second comptroller of the United States treasury. He was a delegate to the constitutional convention of Vermont in 1870; president of the American Bar association in 1880; and Democratic candidate for governor of the state in that year. He became a professor in the law school of Yale in 1881, where he served until appointed minister to Great Britain in 1885. Mr. Phelps remained at the court of St. James until the incoming of the Republican administration in 1889. He was appointed in 1893 one of the counsel in the court of arbitration in the Bering sea controversy, to represent United States. He died at New Haven, Conn., March 9, 1900.

Phelps, Elizabeth Stuart (Mrs. Herbert D. Ward), an American authoress, was born at Andover, Mass., Aug. 31, 1844, her father being Professor Austin Phelps of the Andover Theological seminary, and her mother the daughter of Professor Moses Stuart of the same institution. Besides lecturing, writing for magazines, and engaging in various kinds of work for the advancement of women, she has written a number of novels, including *Gates Ajar* (which passed through several editions in the year of its publication), *Beyond the Gates, Hedged In, The Silent Partner, An Old Maid's Paradise, The Gates Between, Doctor Zay* (in which the question of professional life for women is considered). In 1888, she married Rev. Herbert D. Ward, and since that time in connection with him has written and published *The Master of the Magicians*, and other popular works.

Phelps, William Walter, was born at New York, Aug. 24, 1839, and graduated at Yale college in 1860. After taking a full course of study at Columbia Law school, he entered on the practice of the legal profession at Englewood, N. J., where he also became engaged in extensive business enterprises and acquired great wealth. In 1872, he was chosen fellow of Yale college by the alumni of that institution, and in 1872 was elected a member of congress, in which body he rapidly distinguished himself by his ability and efficiency.

In 1881, he was appointed by President Garfield minister to Austria, and was again elected to congress in 1882, continuing to serve in that body until appointed minister to Germany by Harrison (1889–93). He died at Englewood, N. J., June 17, 1894.

Phen'ogams, a corruption of phanerogams.

Phi Beta Kappa, a collegiate Greek letter fraternity composed of the first third of the senior class in American colleges. It takes its name from the initial letters of its motto, *Philosophia Biou Kubernetes*, "Philosophy is the guide of life." This society was founded in 1776, in the old "Raleigh Tavern," at Williamsburgh, Virginia, by 44 under-graduates of William and Mary college, of whom John Marshall, afterward chief-justice of the United States, was one. Branches were established at Yale in 1780, and at Harvard in 1781, and since then chapters have been formed in many of the universities and colleges of the country, with an active membership, in 1900, of close upon 13,000.

Phidias (*fid'i-as*), the greatest sculptor of ancient Greece, was born about 500 B. C. To Phidias came an opportunity such as comes to few artists. Pericles, having risen to the head of affairs in Athens, resolved to adorn the city with temples and other public buildings, and he therefore not only gave Phidias a commission to execute the more splendid statues that were to be erected, but made him superintendent of all the public works planned for the city. He constructed the Propylæa and the Parthenon, the sculptured ornaments of which were executed under his direct superintendence, while the statue of the goddess of Athena, of ivory and gold, was the work of Phidias himself. He also executed a colossal gold and ivory statue of Zeus for the Olympian temple in Elis; this is considered his masterpiece. In his later years, Phidias was accused of appropriating to himself a portion of the gold designed for the robe of Athena, and of impiety in having placed his own likeness and that of Pericles upon the shield of the goddess, and was thrown into prison, where he died about 430 B. C.

Philadel'phia, the chief city and seaport of Pennsylvania and the third city in population in the United States, is situated on the west bank of the Delaware river at the mouth of the Schuylkill, 135 miles northeast of Washington, and 88 miles southwest of New York. The city is coextensive with the county of Philadelphia, its greatest length being about twenty miles, and its breadth from five to ten miles. Among the most noted buildings are Independence Hall, or old State House, occupied by the Continental congress in 1776; the United States mint and custom-house, the post office, the Masonic temple, which cost over $1,500,000; the Girard college building, the Academy of Fine Arts, the Academy of Natural Sciences, etc. The city hall, begun in 1871 and completed in 1895, is of Massachusetts marble. It covers more than four acres, has 520 rooms, and is the largest city building in the world. The dome and tower, 537½ feet high, is surmounted by

a statue of Penn 36 feet in height. Not far from $20,000,000 have been expended on it. Fairmount park, in which was held the Centennial exposition of 1876, contains nearly 3,000 acres of ground, and is bisected by the Schuylkill river through its entire length of ten miles. In this park is the first established zoological garden in the United States. The Fairmount water-works supply the city with over 100,000,000 gallons of water daily. The public schools of the city, in which there are 3,500 teachers and 150,000 pupils, are maintained at an annual cost of $4,092,855, and besides these, there are over 35,000 pupils taught in Catholic schools. Philadelphia is also the seat of Girard college, and of several other highly-endowed educational institutions, including the University of Pennsylvania, La Salle (Roman Catholic) college, about ten medical and law colleges, and some 40 or 50 hospitals. Philadelphia has become the first manufacturing city in the Union, both in the number of persons employed and in the extent and variety of its productions. An aggregate capital of $400,000,000 is employed in manufacturing, and the value of the productions is $800,000,000 annually, while 250,000 persons are employed. The building of locomotives and the manufacture of iron and steel implements, of carpets and woolens, upholstery goods and cotton goods, employ about 120,000 workmen, and produce $275,000,000 yearly, and there are also several sugar refineries, oil refineries, breweries, and

great chemical works, besides a very considerable foreign commerce.

Philadelphia was founded in 1682 by William Penn, made the capital of Pennsylvania in the following year, and was the central point of the colonies during the war of independence. In Carpenter's Hall, which is still preserved, the first congress met in 1774, and in Independence Hall the Declaration of Independence was signed in 1776. Here the Federal Union was adopted in 1778, and here also the constitution was framed in 1787. Philadelphia was the capital of the Federal Union from 1790 to 1800. Population 1,293,697. See *Philadelphia and Its Environs* (Lippincott).

Philæ (*fīlē*), an island in the Nile, near Assouan and south of Cyrene in Nubia. It is situated near the first cataract, and is a small granite rock, fringed with rich verdure, about 1,200 feet long and 450 broad, almost covered with ancient buildings of great architectural beauty. The Kiosk, Pharaoh's bed, a roofless hall, belongs to the Greek and Roman period, and consists of fourteen great columns with capitals of various patterns, joined together at the lower part by solid walls, 63 feet long and 48 feet wide. The great temple of Isis, to whom the island was sacred, was built by the Ptolemies. It contains representations of the story of Osiris, his birth, bringing up, death, and embalmment by Isis. It was converted into a Christian church in 557.

Phil'ip of Mac'edon, the father of Alexander the Great, was born 382 B. C., and came to the throne 360 B. C., when twenty-two years of age. He was surrounded with many difficulties and dangers, all of which soon disappeared before his decision, energy, and wise policy. In the space of a year, he secured the safety of his kingdom, and was ready to enter upon a policy of aggression, his object being to reduce all the Grecian states to his supremacy. The Greek towns on the coast of Macedonia were the first objects of attack. In Thrace, he captured the small town of Crenides, which, under its new name of Philippi, soon acquired great wealth and fame. After a few years of comparative leisure, he advanced into Thessaly, and ultimately to the strait of Thermopylæ, which he did not attempt to force, as it was strongly guarded by Athenians. After capturing all the towns of Chalcidice, the last of which was the city of Olynthus, he made peace with the Thracians, and the next year with the Athenians. It was during this siege of Olynthus that Demosthenes delivered his famous oration on the crown, in which he sought in vain to arouse his countrymen to a sense of their danger, and cause them to resist the aggressions of the powerful and energetic Macedonian. Philip was now requested by the Thebans to interfere in their behalf in the "Sacred war," which was raging between them and the Phocians. He marched into Phocis, destroyed its cities, and sent many of its inhabitants as colonists to Thrace. In 339 B. C., the Amphictyonic council, composed of several Grecian states, declared war against the Locrians, and the next year appointed Philip commander-in-chief of all their forces. The Athenians were at last alarmed at his approach into Greece in this capacity, and formed a league with the Thebans against him; but their united forces were utterly defeated at the battle of Chæronea, 338 B. C.; and Philip was now master of all Greece. Deputies from the different states met in congress at Corinth, and after resolving to make war on the Persian king, chose Philip as leader of their armies. Philip was busily engaged in preparations for this great enterprise, when he was assassinated by Pausanias, at a festival to celebrate the marriage of his daughter with Alexander of Epirus, 336 B. C., and was succeeded by his son, Alexander the Great. Philip was faithless in the observance of treaty obligations, and utterly unscrupulous as to the means by which he gained his end; but his great ability both as a king and a soldier is conceded by all historians.

Phil'ip, sachem of the Wampanoag tribe of Indians, was the second son of Massasoit, who for nearly thirty years had been the stanch ally of the pilgrim settlers. In 1661, Philip succeeded his elder brother and kept the treaties of his father for several years. But, at length, goaded by the encroachments of the whites, he formed a confederation of tribes, amounting to nearly 10,000 warriors, and in 1675 the war known as "King Philip's war," broke out. The Indians surprised and murdered a great many colonists, but were eventually overcome, and in 1676 Philip himself was captured and slain in Rhode Island. Afterward his body was drawn and quartered and his head was exposed on a gibbet at Plymouth for a number of years. See *Entertaining History of King Philip's War*, and Irving's *Sketch Book*.

Phil'ip II., of France, called Philip Augustus, on account of his great abilities and successful administration, was born August 21, 1165, and died at Nantes, July 14, 1223. He was crowned joint king with his father, Louis VII., in 1179, and on the death of the latter, in the year following, he came into full possession of the kingdom. He was one of the greatest monarchs of the Capet dynasty, while he confirmed his power by marrying Isabella of Hainault, the last direct descendant of the Carlovingians. On the accession of Richard the Lion-hearted to the throne of England, in 1189, Philip and he set out together on the third crusade. After staying three months in the Holy Land, Philip returned home, binding himself by a solemn oath not to molest Richard's dominions; but very soon

after his arrival in France he invaded Normandy, while Richard was a prisoner in Germany. Richard's release from imprisonment and his return to England occasioned a war between the two monarchs, which continued till 1199, when peace was secured through the mediation of Pope Innocent. Richard dying shortly after, war again broke out between France and England on account of the rival claims of King John and his nephew Arthur to Richard's French possessions. Philip espoused Arthur's cause, and after the murder of that prince took possession of Normandy, Maine, Anjou, and Touraine, and added them to his dominions. The great victory of Bouvines, which Philip won, Aug. 29, 1214, over the English and the Emperor Otho of Germany, firmly established his throne, and he was able to devote the remainder of his life to reforms of justice and to building and fortifying the city of Paris.

Phil'ip IV., surnamed *Le Bel*, or "the fair," king of France, was born at Fontainebleau in 1268. He succeeded his father Philip "the rash," in 1285, and by his marriage with Queen Joanna of Navarre he obtained Navarre, Champagne, and Brie. The chief feature of his reign was his contest with Pope Boniface VIII., which grew out of his attempt to levy taxes from the clergy, which the pope directed them not to pay. In 1300, Philip threw the papal legate into prison and summoned the three estates of France — clergy, nobles, and burghers — to which Boniface replied with the bull, *Unam Sanctam*. Philip caused the bull to be publicly burned, and confiscated the property of the prelates who had sided with the pope. Boniface then excommunicated him, but Philip sent William de Nogaret to Rome, who, with the aid of the Colonnas, seized and imprisoned the pope. Though released after a few days by a popular rising, Boniface soon afterward died. In 1305, Philip obtained the elevation of one of his own creatures to the papal chair as Clement V., and seated him at Avignon, which place was the residence of the head of the church for seventy years thereafter. This period of papal history is often called "the seventy years' captivity." Philip compelled the pope to condemn the Templars in 1310, and to decree the abolition of the order two years later. They made a heroic defense, but were condemned and burned by thousands, their wealth being appropriated by the cruel and rapacious Philip. The grand-master, Jacques de Molay, was burned March 18, 1314, and at the stake he is said to have summoned Philip to appear before the judgment seat of Almighty God within a year and a day and the pope within forty days. Whether this summons was actually uttered or not, both the pope and the king died within the periods assigned to them, the latter's death occurring Nov. 29, 1314. Philip strove throughout his reign for the suppression of feudalism and the introduction of the Roman law, but under him the taxes were greatly increased, and the property of the Jews was confiscated in order to satisfy the avarice of the king; and when these means were insufficient to furnish him all the money he desired, he caused the currency to be greatly debased.

Phil'ip VI. (of Valois), king of France, was born in 1293, and became regent of France on the death of Charles IV. in 1328. Philip remained regent during the pregnancy of Charles' widow, but when she was delivered of a daughter, he caused himself to be crowned king at Rheims, the Salic law excluding females from the throne. Philip's right was disputed by Edward III., of England, the grandson of Philip IV., whose mother was the sister of Charles IV. Edward claimed that although his mother could not herself inherit the crown of France, he, as her son, might. In support of this claim, weak as it was, Edward declared war against Philip in the year 1337, which was the beginning of the long wars between England and France, which were brought to a conclusion only by the victories of Joan of Arc, nearly a hundred years later. Edward's first campaign was not attended with any important results, but in 1346, accompanied by his son, known in history as the Black Prince, then but sixteen years old, he marched almost to the gates of Paris, and won a decisive victory over Philip's forces at Crécy. The next year, Calais was taken by Edward, after which a truce was concluded between the two countries, which continued till after Philip's death, which occurred Aug. 22, 1350.

Phil'ip II. (king of Spain), son of Charles V., was born at Valladolid, May 21, 1527. In the year 1543, Philip married Mary of Portugal, who died three years later, after bearing a son, the ill-fated Don Carlos. Eight years after her death, he married Queen Mary of England, who was several years his senior. After remaining in England with her about a year, he returned to Brussels, in the month of September. By the abdication of his father, the next year, Philip became sovereign of Spain, the two Sicilies, the Netherlands, Milan, Naples, Mexico, Peru, and the Spanish possessions in Africa and the East Indies. Philip's marriage with Queen Mary was not a happy one; and after her death, in 1558, he married his third wife, Isabella of France. Philip was an intense bigot in religion, and put himself at the head of the Catholic party in Europe; but the main object of his policy was to concentrate all power in himself, and to suppress everything in the nature of free institutions within his dominions. He found the inquisition a very effective means of tyranny in Spain; but in the Netherlands a formidable revolt was organized, and, under the leadership of William the Silent, the seven provinces formed the union of Utrecht, in 1579, and maintained a successful war against Spain, until their in-

dependence was fully achieved, although William himself was assassinated, at the instigation of Philip, in the year 1584.

After the death of William the Silent, Philip proceeded to organize the "Invincible Armada" for the conquest of England, placing the same under the command of Alexander Farnese, prince of Parma; but his ships were scattered by the storms of the sea, and the valor of English sailors, and only defeat and disaster resulted from all his plans and preparations. The one great triumph of Philip's reign was the naval victory of Lepanto, won by his half-brother, Don John of Austria, over the Turks.

The desperate heroism of the Netherlanders and the defeat of the Armada, added to financial distress at home, embittered the last years of Philip, and he died of a lingering and loathsome disease at the Escurial, Madrid, Sept. 13, 1598, being succeeded by Philip III., his son by his fourth wife, the Archduchess Anne of Austria.

Philip possessed considerable ability, but little political wisdom, and although he undertook a great many vast enterprises, scarcely any of them led to a profitable result. He was cold and austere without being virtuous, and although a bigot and a persecutor, he had no real respect for honor or religion. There is hardly a character in history whom historians have more unanimously united in condemning. See the histories of Prescott, Motley, and Froude.

Phil'ip V., the first Bourbon king of Spain, was born at Versailles, Dec. 19, 1683, his father being the Dauphin Louis, son of Louis XIV. of France. In the year 1700, the crown of Spain was bequeathed to him by Charles II. He entered Madrid in 1701, and after a long struggle with his rival, the Archduke Charles, was left in possession of his throne by the peace of Utrecht in 1713. His queen, Maria Louisa, dying in the next year, Philip soon after married Elizabeth Farnese, of Parma, "the termagant," to use Carlyle's phrase, who disturbed the peace of Europe for thirty years. Her dearest wish was to drive the Hapsburgs out of Italy in the interests of her sons by a former marriage; but all her efforts resulted only in securing the two Sicilies for Don Carlos. Spain joined the coalition against Maria Theresa; and her younger son, Don Philip, was at first successful in conquering the Milanese; but as soon as the Silesian war was closed by the peace of Dresden, the Austrian queen sent her troops into Italy and drove out the Spaniards. At this crisis Philip, who had been in a state of mental stupor for several years, died at Madrid, July 9, 1746.

Phil'ip, John Woodward, an American naval officer, was born at New York city, Aug. 26, 1840. In 1861, he graduated from the naval academy, and served as midshipman on board various vessels blockading the Gulf harbors and also in the James river fleet. He became a lieutenant in 1862, and lieutenant-commander in 1866; commander in 1874; captain in 1889, and commodore in 1898. He was wounded at Stone river during the Civil war. During the years of peace he made a tour of the world in command of the Woodruff Scientific expedition (1877). He was in command of the battleship *Texas* during the fight off Santiago bay, in the Spanish-American war; and his request of his men not to cheer over their dying foes excited widespread comment. He was a very earnest Christian soldier, and led his sailors and marines in prayer at the close of the fight above mentioned. He was for a time in command of the North Pacific squadron, and later assigned to the command of the navy-yard at Brooklyn, where he died, with the rank of rear-admiral, June 30, 1900.

Phil'ip the Bold, son of John the Good, of France, and founder of the second and last ducal house of Burgundy, was born Jan. 15, 1342. He was present at the battle of Poitiers, in 1356, when only fourteen years of age, and displayed such heroic courage in risking his own life to save his father's, that he earned the title of Le Hardi, or "the Bold." He shared his father's captivity in England, and on his return to France, in 1360, received as the reward of his bravery the duchy of Touraine, and in 1563 also the duchy of Burgundy. Flanders, Artois, Rethel, Nevers, and the county of Burgundy fell to him by the death of his father-in-law, the count of Flanders, in 1384, and his firm and wise government quickly won him the esteem and affection of his subjects. He encouraged arts, manufactures, and commerce, and his territory was one of the best governed in Europe. During the minority and imbecility of his nephew, Charles VI. of France, he acted as regent of that kingdom, and displayed great wisdom and ability both in preventing insurrection within the state and in defending it against the attacks of the English. He died April 27, 1404.

Phil'ip the Good, son of John the Fearless, and grandson of Philip the Bold, was born at Dijon, the capital of Burgundy, June 13, 1396. In order to avenge the death of his father, who had been assassinated at the bridge of Montereau, at the instigation of the dauphin (afterward Charles VII.), when he succeeded to the duchy of Burgundy, he entered into an alliance with Henry V. of England, recognizing him as the rightful regent of France and heir to the throne after Charles VI.'s death. This agreement, although it disregarded the terms of the Salic law, was sanctioned by the king and the states-general of France in the treaty of Noyes in 1420; but the dauphin refused to accept it and took up arms. He was, however, defeated at Crévant and at Verneuil, and driven beyond the Loire. Some time

after this, on account of some insults of the English viceroy, Philip made a final peace with Charles, who gladly accepted the hard conditions prescribed by Philip. The English in revenge committed great havoc among the merchant navies of Flanders, which so irritated Philip that he declared war against them, and with the assistance of the king of France, gradually expelled them from their French possessions. Under Philip, Burgundy was the most prosperous and tranquil state in Europe; and in spite of several insurrections in Ghent and in Bruges, caused by the imposition of heavy taxes, he was greatly beloved by his people. He died at Bruges, July 15, 1467. See Barante's *History of the Dukes of Burgundy and the House of Valois.*

Philippine Islands, The, a group of islands in the Pacific ocean lying southeast of Hong-Kong, China, which were discovered by Magellan in 1521. He was slain a few months later upon one of the smaller islands during the progress of one of the numerous tribal wars. Spain attempted to make good her claim to these lands a few years afterward by sending out an expedition under Villabos who named the islands in honor of the heir to the Spanish throne, afterward Philip II. The first attempts at settlement were made upon Zebu; but in 1581 Manila was founded, and it has since continued to be the chief city of the archipelago. The exact number of the islands is unknown, but it is sometimes given as "more than 1,200." Most of the islands, however, are small, and many of them uninhabitable. The largest islands are nine in number, and they are called Luzon, Mindanao, Samar, Mindoro, Panay, Leyte, Masbate, and Cebu. The total area of the habitable islands is supposed to be about 114,326 square miles. The population is also a matter of uncertainty, but is given as between 5,985,000 and 7,000,000. Some estimates are even higher; but as they are all more or less guesswork they are of little value. The census of those lately under Spanish rule is somewhat less than 6,000,000. The islands are exceedingly fertile, and their mountains are clothed with forests of inestimable value. The one chief product of the islands is hemp; sugar, coffee, cocoanuts, tobacco, and indigo following in the order named. Coal to the amount of 60,000 tons a year has been mined in Cebu, and gold-mining has at times promised important developments. The chief imports of the islands are cotton goods, silks, drugs, and chemicals. The total value of exports in 1894 was $33,149,984, and the imports the same year reached $28,529,777. Both exports and imports fell off the next year; and during the insurrection which broke out in 1896 business was greatly depressed. In January, 1898, peace was agreed upon by a compact between the Spanish authorities and Aguinaldo, leader of the Filipinos, the terms of which do not appear to have been kept by either party. In April, 1898, war broke out between Spain and the United States, the first serious encounter being the battle of Manila Bay, May 1, 1898, when the Spanish squadron under Admiral Montojo was completely destroyed. At the close of this war, Spain (by treaty Dec. 10, 1898) ceded the Philippines to the United States, $20,000,000 being paid to Spain. Meantime, Aguinaldo proclaimed the Philippines an independent republic and thus brought on a conflict between his followers and the United States, which was terminated only by his capture in April, 1901. On July 4, 1901, military was superseded by civil government, under Wm. H. Taft, of Ohio, who was appointed civil governor of the islands. Manila, with a population of 154,000, upon the island of Luzon, is the seat of the government constituted by the authority of congress under the personal direction of the President of the United States. See AGUINALDO, and SPANISH-AMERICAN WAR. See also Dean C. Worcester's *The Philippine Islands.*

Philippopolis (*fil-ip-op'ō-lis*), capital of eastern Rumelia or southern Bulgaria, on the navigable Maritza, 110 miles from Adrianople. It manufactures silk, cotton, tobacco, leather, etc. Population 41,068, of whom one-half are Bulgarians, the remainder being Turks, Greeks, etc. Philippopolis was occupied by the Russians in 1878, and in 1885 a revolution broke out here which led to the incorporation of eastern Rumelia with Bulgaria.

Philistines (*fil-is'tinz*) ("strangers"), a people mentioned in the Bible as being in frequent conflict with the Jews, and who lived on the coast of the Mediterranean to the southwest of Judæa. Their first appearance as the enemies of Israel was during the period of the Judges. They were subject to five princes who ruled over the cities or provinces of Gaza, Ashdod, Askalon, Gath, and Ekron. In the time of Eli they were so powerful that they even carried away the ark. Saul, the first king of Israel, was engaged in frequent conflicts with them, and both he and his sons fell in a disastrous battle against them at Gilboa. David won a great many victories over them, and under Solomon most of their territory was annexed to that of the Jews, and they continued in subjection to the kings of Judah until the reign of Ahaz, three hundred years later, when they revolted and made great havoc in the territory of Judah. Hezekiah, the son and successor of Ahaz, however, subdued them and brought them to obedience, without the aid of the Egyptians. Under the later kings of Judah they appear, from the menaces of the prophets, to have brought many calamities on the Jews — if they did not recover their full independence. In the time of the Maccabees the Philistines were Syrian subjects, and in the time of Herod the Great they appear no longer to have an existence as a separate race or nation,

even the name of their country being merged in that of Palestine.

Phil'lips, Wen'dell, the distinguished orator and abolitionist, was born of wealthy and aristocratic parentage at Boston, Mass., Nov. 29, 1811. After taking a course of several years' study in the public Latin school of his native city, he entered Harvard college, from which he graduated in 1831, at the age of twenty. While yet in his collegiate course Phillips was noted not only for his superior scholarship, but for his oratorical gifts and the marked purity and dignity of his character. Strange to say, however, this young man who afterward became the special champion of the slave in the face of the civilized world was at this time a representative aristocrat. In 1834, having taken a three years' course of legal study, Mr. Phillips was admitted to the bar at Boston, but his silvery voice was not to be confined within the court rooms of that city — a nation was waiting to be thrilled and electrified by his eloquent speech. A little more than a year after entering upon the practice of his profession he witnessed the mobbing of William Lloyd Garrison at Boston, which made a deep and lasting impression upon his mind and awoke him to serious thought upon the evils of slavery. Two or three years later, the young lawyer attended a meeting of an anti-slavery convention at Lynn, where he delivered an eloquent address, in which he avowed himself an abolitionist. But it was in Faneuil hall, in the latter part of the same year, that Mr. Phillips, then only twenty-six years old, delivered the first of those marvelous philippics that did so much to arouse the anti-slavery sentiment of the nation, the occasion being a meeting called to denounce the murder of E. P. Lovejoy at Alton, Ill., for advocating anti-slavery sentiments in his paper published at that place. One of Mr. Phillips' auditors on that occasion says of his address: "I had heard him once before (in his first anti-slavery speech at Lynn), as a few others in that great meeting probably had, and my expectations were high; but he transcended them all and took the audience by storm. Never before, I venture to say, did the walls of the old 'Cradle of Liberty' echo to a finer strain of eloquence." From that time on Mr. Phillips continued the faithful and unflinching opponent of slavery, raising his voice against it throughout the land and devoting his gifts and varied powers to the single purpose of its abolition and destruction. But although the very prince of agitators, he himself was always calm and unperturbed. Sooner, no doubt, than he ever anticipated was the fruition of his hopes fully realized, in the Emancipation Proclamation of President Lincoln.

Although the matter of Mr. Phillips' speeches was nearly always fiery and impassioned, his delivery as well as his manner on the platform was invariably calm, reserved, perfectly easy, and natural, giving him a power over his audiences that compelled their interest and attention, even when they most disagreed with him. Very appropriately was he called "the unagitated agitator." He died at Boston, Feb. 2, 1884.

Phillips'burg, N. J., a city of Warren county, on the Delaware river, opposite Easton, Pa., where the river is crossed by two iron bridges. It is situated in a fine agricultural, limestone, and iron-ore region. Besides extensive iron works, a rolling mill, boiler and machine works, and a reaper and mower factory, there is a silk mill and several other industries. There are good schools in the town. Population 10,052.

Phi'lo Judæ'us, the distinguished Jewish philosopher of the 1st century, was born at Alexandria about 20–10 B. C. Belonging to a wealthy family, he received a liberal education, and such was his zeal for learning that he had passed through the ordinary course of Greek studies at a very early age. But he considered philosophy the mistress of all sciences, and he tells us that metaphysical speculation was the only thing that could give him complete pleasure and satisfaction. He was acquainted with Homer, Plato, and the Greek tragedians; but with all his Greek culture he remained a Jew, holding Jewish philosophy as the highest wisdom and the divine revelation given to Moses as the source of all true religion. Of his life little is known, except that he made one visit to Jerusalem, and that when over fifty years of age he went to Rome as the advocate of his Jewish brethren in Alexandria, who refused to worship the emperor Caligula.

To Philo the divinity of the Jewish law is the basis and test of all true philosophy, and although he admits that some portions of the Jewish scriptures may be interpreted in an allegorical sense, he yet insists that in general their literal meaning is the one that must be accepted. At the same time he frequently presents the allegorical meaning as the one really divine, and sometimes, without expressly denying the literal meaning, treats it as absurd. While thus cherishing philosophy, he held fast to his reverence for the law, and nearly all his writings were an effort to harmonize the two. In a word, he sought to be a disciple of both — a Greek, with all the refinement of Greek culture, and at the same time a pious and faithful Jew. According to Philo, God alone is the real Good, the perfect and final cause of all things, which ceaselessly flow outward from Himself. He is the primeval light, which cannot be seen by itself, but which may be known from its rays that fill the whole world.

Philo holds firmly to the belief in immortality; but future rewards and punishments are not regarded by him in the ordinary sense of those terms. Virtue and sin have their rewards within themselves; but the soul, which is "pre-existing," carries this con-

sciousness with it in a more intense and exalted manner. Paradise is oneness with God; there is no hell for souls without a body, and no devil in Philo's system. See *Philo-Judæus*, by Drummond.

Philoctetes (*fil-ok-tē'tēz*), a famous archer, the friend and armor-bearer of Hercules, who bequeathed him his bow and poisoned arrows. As one of the suitors of Helen, he led seven ships against Troy; but being bitten in the foot by a snake, or, according to one account, wounded by his own arrows, as his wound gave forth an unendurable stench, the Greeks left him on the island of Lemnos, where he remained ten years. But an oracle declaring that Troy could not be taken without the aid of Philoctetes, Ulysses and Neoptolemus were sent to Lemnos to bring him to the Grecian camp, where, healed by Æsculapius or his sons, he slew Paris and otherwise assisted in the capture of Troy.

Philology (*fi-lol'ō-gy*). This word is derived from two Greek words, *philos*, "a friend," and *logos*, "a word"; and like many other words it has varied greatly in its meaning. In the time of Plato it meant the love of discussion, confined mainly to the moral and social question in which Plato delighted; and the method of discussion was the Socratic one by asking questions. At Alexandria, the "philologer" gave attention to all the knowledge of his day, brought together for the first time in the great library in that city; but the scholars of Alexandria applied themselves especially to the study of the older Greek literature. It widened again at the revival of learning to include the study of grammar, rhetoric, literature, poetry, archæology — in a word, all the "humane" studies. Since the middle of the 19th century, the word has been used in a more restricted sense; so that, whereas philology formerly meant the study of the literature of the world, it is now limited to the study of languages, apart from the literature embodied in them. It is the science which deals with the origin, development, and general structure of the different languages of the world and of human language as a whole. In the progress of this study not only has great light been thrown on the origin of different languages; but they have been classified and grouped, and in many cases languages which seemed to have no points of similarity have been traced to a common origin. Sir William Jones, the great oriental linguist, declared that "no philologer could examine the Sanskrit, Greek, and Latin without believing them to have sprung from the same source, which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for believing that both the Gothic and the Celtic had the same origin with the Sanskrit." There are two main classes of languages: First, those which show no signs of inflection — for example, in which the plural of man is not formed by a vowel change (as our men), nor by an added suffix (as in Latin homin-*es*), but by a combination of two words (as our man-kind); second, those which are inflected in greater or less degree. This latter class is divided into two great families: (1) the Semitic, comprising the Hebrew, Aramaic, Arabic, Syriac, etc.; (2) the Indo-Germanic or Aryan family, the chief languages of which are the Sanskrit, the Armenian, the Albanian, the Latin, the Celtic, the Teutonic or Germanic, the Slavonic, etc. See Isaac Taylor's *Origin of the Aryans*.

Philos'ophy (Greek *philos*, "a friend," and *sophia*, "wisdom"). A complete and final definition of this word is impossible, as the objects of the science, its methods, and even the possibility of its being or becoming a science, are still matters of debate between different schools. Philosophy has been called the "mother of the sciences," as it was only by slow degrees that the separate sciences came into life, each one of them being developed and formulated by men imbued with the philosophical spirit, which is the "love of wisdom." As the number of special sciences increased, philosophy could no longer in a strict sense "take all knowledge to be her province"; but her claim to be the only science of the universe as a whole was not thereby given up, but rather emphasized. Unity and harmony in one conception of the universe is th aim which philosophy always has in view. Whether this idcal can ever be reached by man is another question; but the conception of a complete system of things satisfactory to the reason and the moral sense must ever be the spring and inspiration of philosophical effort. The philosopher, therefore, always has his eye upon the whole, and his function is to study the relation of all the parts to the whole and to one another. No one thing can be fully understood except in the light of its relation to other things, and therefore the philosopher seeks to penetrate the reason and essence of things and to know the *why* and the *wherefore* of all the phenomena of nature. The history of philosophy is an important part of philosophical study. Indeed, philosophy cannot be studied with profit apart from its history.

Thales of Miletus is generally reckoned the first Grecian philosopher, and the history of philosophy is generally said to commence at his time, about 600 years B. C. It is usual to divide the history of philosophy into three distinct periods: (1) Ancient or Greek philosophy, from the time of Thales to about 500 A. D.; (2) mediæval philosophy, from 500 to 1600 A. D.; (3) modern philosophy, from 1600 to the present era. Ancient philosophy is again divided into three periods: (1) The pre-Socratic philosophers — Pythagoras, Parmenides, Anaxagoras, and others — who devoted their attention mainly to the phenomena of external things; (2) Socrates and the sophists who turned man's attention upon himself; (3) the idealistic systems of Plato

and Aristotle. The Stoics, Epicureans, Sceptics, and later the Neo-Platonists and other schools, make up the history of philosophy until the downfall of the Roman empire and the death of Bœthius. Mediæval philosophy is mainly an effort to apply the logic of Aristotle to the doctrines of the church and to harmonize his philosophy with Christian theology. Bacon and Descartes, in the beginning of the 17th century, may be considered the founders of modern philosophy, to give an adequate history of which would require volumes. See English translations of histories by Erdmann, Ueberweg, and Schwegler.

Phloem (*flō'ĕm*), (in plants). A woody strand is known as a vascular bundle, because it contains different forms of the cells known as vessels. Each individual vascular bundle consists of two elements, the wood and the bast. The bast elements of a vascular bundle taken together are called the "phloem," in contrast with the wood elements, which are called the "xylem." In an ordinary tree it is the xylem tissue which accumulates as the permanent wood, while the phloem tissue forms the fibrous lining of the bark. In the stems of Monocotyledons, as the cornstalk, the vascular bundles are scattered, and no bark is formed, but each bundle is composed of phloem on its outer side and xylem on its inner side. In the vascular bundles of the stems of most ferns the phloem completely surrounds the xylem; while in all roots the phloem and xylem occur in alternate strands about the center. The phloem is concern in the transfer of foods.

Phlox (*flŏks*), a genus of the *Polemonium* family containing about 30 species, which are natives of North America and northern Asia, nearly all of the species being found in North America. They are mostly hardy herbs with usually showy red, violet, or white flowers. The perennial species are among the most popular of garden plants. Perhaps one of the best-known phloxes of cultivation is *P. drummondii*, occurring throughout Texas and cultivated everywhere. *P. subulata* and its varieties are the best known of the dwarf creeping kinds, and are frequently called "ground" or "moss pinks." *P. maculata*, the wild Sweet William, is probably the best known and widely distributed of the wild forms.

PHLOX.

Phocion (*fō'shi-on*), an Athenian general, was born about the end of the 5th century B. C. Although of humble origin, he studied under Plato, and perhaps under Diogenes also. In 341 B. C., Phocion was successful in overcoming the Macedonian party in Eubœa and in restoring the ascendency of Athens, and the next year, being sent to the relief of Byzantium, he forced Philip to abandon the siege of that city and to evacuate the Chersonesus. A little later, however, he placed himself in opposition to Demosthenes and others who advocated resistance to Philip's demands, and after the assassination of Philip, in 336 B. C., we find him striving to repress the desire for war among the Athenians, on account of which many regarded him as a traitor; but this charge was doubtless unjust. On the death of Alexander the Great, Phocion endeavored in vain to hinder the Athenians from going to war with Antipater. After the death of Antipater he was involved in the intrigues of Cassander, and was forced to flee to Phocis, where he was delivered up to the Athenians and condemned to drink hemlock (317 B. C.). His body was carried by some of his friends to Eleusis and there burned.

Phœ'be, a small fly-catcher nesting about houses and other structures. Its nest of moss and mud may be placed under bridges, in barns, sheds, the shelter of piazzas and other similar situations. It is about seven inches long, dark above and white below, tinged with yellow. Its bill is black. It is sometimes called pewee, but that name is better reserved for the wood-pewee. It winters north of the frost-line. It owes its name to its song of *pewit-phœbe*. See PEWEE.

Phœ'bus ("the bright"), an epithet and afterward a name of Apollo. It had reference to the youthful beauty of the god and to the radiance of the sun, when, at a later period, Apollo became identified with Helios, the sun-god.

Phœnicia (*fē-nĭsh'i-a*), the name of a certain territory lying on the east coast of the Mediterranean, north of Judea. The boundary lines of Phœnicia differed at different times, but its length was generally about 200 miles and its average width about 20 miles. It is impossible to say when the first Phœnician settlers entered the country; but it is generally conceded that they did not come from one region, but from several different directions, and they grew into one nationality very slowly. The history of Phœnicia covers nearly 2,000 years; and although our sources of information are very meager, it may be divided into four distinct periods. The first of these comprise the immigration and gradual development of the various tribes until the historical time when Sidon began to take the lead, about 1,500 B. C. The second period dates from the conquest of Palestine by the Hebrews, when Sidon had already become

the "first born of Canaan," as recorded in Genesis. The flourishing state of its commerce and manufactures is also seen from many passages in Homer. The gradual ascendency of the rival city of Tyre marks the beginning of the third period, in which Phœnicia attained her greatest power and glory, her ships covering every sea, and her commerce extending far and wide among other nations. During the reigns of David and Solomon (980–917 B. C.) very friendly relations existed between the Israelites and the Phœnicians under Hiram, king of Tyre. As each country needed what the other could supply, a very close alliance was formed, between Hiram and Solomon especially, Hiram furnishing a portion of the material for Solomon's temple at Jerusalem. By this time, too, the Phœnicians had not only planted colonies on the coasts and islands of the Ægean and Mediterranean seas, but had passed through the Strait of Gibraltar, and established themselves on the western coast of Spain and of Africa, while at the same time their alliance with the Hebrews permitted them to find their way to the Indies by the Red sea. Although at first they traded in the wares of Egypt and Assyria, they soon became manufacturers on a very extensive scale, and drew the whole world into the circle of their commerce. The two chief articles of their manufacture were glass and the purple dye obtained from a shellfish of the Mediterranean. Purple was one of the most noted luxuries of ancient times — especially in Asia. In temples and palaces for gods and men purple garments, hangings, curtains, and veils were used very extensively; and Alexander the Great found in Susa alone a store of purple worth 5,000 talents. Sidon's principal production was glass — invented there by accident, it was said; but most probably the invention came from Egypt. The mining operations of the Phœnicians were very extensive at this time; and they well understood how to work the metals thus obtained. The description of the mining process in Job xxviii. 1–11, must have been derived from a sight of the Phœnician mining works. The art of pounding brass had certainly reached a high degree of perfection to enable Hiram to execute such works for Solomon's temple as are described in the Bible. Hiram's reign seems to have been the beginning of the end of Phœnicia's prosperity and glory. He was succeeded by his son Baleastartus, who died after a reign of seven years, and a long series of political calamities and civil wars then ensued. The fourth and last period of Phœnician history may be dated from the middle of the 8th century B. C., when Shalmaneser, king of Assyria, besieged Tyre for five years without being able to take it. Peace was concluded on terms that were very favorable to Tyre; but two centuries later Phœnicia was conqured by Assyria. She was afterward conquered by Nebuchadnezzar, and remained subject to Babylon until the capture of that city by Cyrus the Great, when she became a part of the Medo-Persian empire; and when Persia was conquered by Alexander the Great, the last shadow of Phœnicia's independence passed away. Since 65 B. C., the Phœnician territory has been a part of Syria. The religion of the Phœnicians was like that of all ancient Semitic religions — except that of the Hebrews — a kind of Pantheistic worship of nature, their two principal deities being Baal and Astarte. See *History of Phœnicia*, by Rawlinson.

Phœ'nix, the name of a mythical Egyptian bird, which is said to have burned itself, when a new Phœnix arose out of its ashes.

Phonet'ics, the science of the sounds of the human voice. Sound is produced by the expulsion of air from the lungs through the windpipe, and when this air in its passage through the throat sets the vocal cords in vibration, what we call "voice" is produced. After passing through the throat the voice enters the mouth, or nose, or both of these. As a practical science, phonetics comprehends not only a knowledge of the various sounds uttered in human speech, but also the invention or discovery of an alphabetical symbol to represent each of them. The sounds of the voice are of two kinds — "fixed sounds," where the cavities of the mouth remain unchanged during the passage of the air, and "glides," where these cavities are constantly changing, or, in other words, where the utterance is variously modified by the tongue, palate, lips, and teeth. The former of these are called *vowels*, and in the English language are represented by the letters, *a, e, i, o, u, y;* the latter are called consonants-with-sounders, as they are sounded with the vowels, but not alone. The great variations in spelling and pronunciation in the English tongue have long been a source of perplexity to foreigners learning our language, and have caused many "phonetic reformers" to arise, with plans for producing uniformity; but none of these have ever been adopted, except in the case of a few words. Perhaps the reason of this is that however "irregular" may be the spelling of so many words, yet the forms in which they are written have become as firmly fixed in our mental habit as are the sounds they represent and the ideas conveyed by those sounds; hence we can never consent to any changes, except those that are gradual, and proceed as by a process of evolution. Another difficulty in reference to the phonetic reform would be, that even if it were possible to devise a fixed alphabetical symbol for every sound or combination of sounds, to which all good writers would conform, the pronunciation of words would at once begin to vary, and in the course of time our spelling and pronunciation might be as "irregular" as they now are.

Pho'nograph, an instrument invented by Edison in 1877, for the purpose of recording

and reproducing words spoken by the human voice. Leon Scott had already shown that, by speaking in front of a diaphragm, on the rear side of which was fixed a stylus, he could obtain a graphical record of the human voice on a cylinder rotating behind the diaphragm. The step which Edison made was to introduce a wax cylinder and a needle-point attached to the diaphragm. On rotating the wax cylinder, the needle-point cuts a groove. And if while this groove is being cut one "talks to the diaphragm" the indentations of the needle-point in the wax will vary with each pulsation of the voice. The axis of the cylinder is provided with a screw so that the groove takes the form of a spiral as the cylinder is rotated and translated while the stylus is fixed in one position. A record having been impressed upon the wax, it is only necessary to allow the stylus again to trace the groove in order to impress upon the diaphragm exactly—or nearly exactly—the same vibrations which originally produced the groove. In this way, the phonograph is made to repeat whatever is said to it. A new phonographic principle has recently (1900) been invented by a Danish engineer, Poulsen, and was exhibited practically for the first time at the Paris Exposition. Poulsen uses the current in a telephone circuit to magnetize a strip of steel tape which is drawn continuously between the poles of an electro-magnet—the electro-magnet being energized by the telephone current. The record of anything spoken into the telephone is thus stored up in the magnetization of the steel tape. Accordingly, when the steel tape is again drawn between the poles of the electro-magnet, the telephone in the circuit will repeat, owing to currents induced by the steel tape, whatever was originally spoken to it. Still a third phonographic principle has recently (1901) been devised by Nerust; but has not yet been perfected. It is based upon the electrolysis produced by an electric current.

Phonog'raphy. See SHORTHAND.

Phonom'eter is the name given by Thomas Edison to an instrument of his own invention for testing the force of the human voice in speaking. It consists chiefly of a mouthpiece and diaphragm, behind the latter of which is placed a delicate mechanism which operates a 15-inch fly-wheel by means of which a hole can be bored in an ordinary pine board.

Phonophore (*fō'no-fōr*), **The,** is a device of Mr. Langdon Davies of London, England, for transmitting electric signals through circuits which are not closed. Messages have been sent over wires open at both ends, under circumstances which would render ordinary telegraphing impossible. The same wire has been used at once for ordinary telegraphing and for the transmission of phonophore signals. When, the resistance having been greatly increased, the ordinary signals ceased, those of the phonophore continued as distinct as before. The transmitter is fitted with a vibrating reed at one end, and the receiver with a stretched steel band at the other, which can be tuned to the same note.

Phosphorescence (*fŏs'fŏr-ĕs'sens*). When a body emits light because it has been raised to a high temperature, we describe the phenomenon by the name *incandescence;* but when a body emits light without being raised to a correspondingly high temperature, the process is called *luminescence.* A piece of sugar cut in the dark will emit a faint light; this is an example of luminescence. A solution of sulphate of quinine held in ultra-violet light will emit a faint blue light; this is another example of luminescence, which is generally known as *fluorescence.* The Germans call it *photo-luminescence,* because it is an effect produced by light. Red ink, when made of eosin, behaves in the same way as quinine. But as soon as the illumination ceases, these bodies cease to give off their fluorescent light. There are certain other bodies, however, such as sulphides of barium, calcium, and strontium which continue to exhibit fluorescence even after illumination has ceased. This phenomenon of persistent fluorescence is called *phosphorescence.* Becquerel has proved that most bodies exhibit phosphorescence, but only for a very short time after illumination. The student should carefully note that the glow exhibited by phosphorous in the dark is due to slow oxidation, and is not a case of phosphorescence at all. Properly classified, it is a case of *chemical* luminescence.

Phos'phorus, one of the non-metallic elements. At ordinary temperatures it is an almost colorless, or faintly yellow, solid substance, having the glistening appearance and consistence of wax. If it be heated to 140° F. in the air, it catches fire and burns with a brilliant white flame. It is so inflammable as to burn by mere friction at ordinary temperatures. Even the warmth of the hand may set it to burning. Hence, in experiments, care must be taken lest the hands be severely burned. It is kept in water lest it may spontaneously get on fire. It shines in the dark, from the slow combustion, which it undergoes. Taken internally, it is a powerful irritant poison. Persons engaged in the manufacture of matches are frequently seriously affected by its fumes. Scientists have overcome this danger to some extent by the discovery of red phosphorus, which is prepared from the ordinary phosphorus by heating it in a closed iron vessel. Phosphorus is not found in an uncombined state in nature. It was first discovered by Brandt, in 1669. Bones at present furnish a large part of the phosphorus of commerce. Bones are burned to whiteness and powdered, then mixed with sulphuric acid to decompose the phosphate of lime in the ash; the solution of the superphosphate is

evaporated to a syrup, mixed with charcoal and then distilled, when the phosphorus rises in vapor and is condensed. The mineral apatite is also used instead of bones.

Photius (*fō'shi-us*), a patriarch at Constantinople, whose chief distinction is his influence in bringing about the separation between the Latin and the Greek churches. The separation did not completely take place during his time, but its beginning did. Steps were taken under his leadership which could not be retraced. Ignatius tried to correct the vices of Michael III., Byzantine emperor (842–867). For this he was deposed and banished, and Photius, although a layman, was appointed in his stead, and was hurried through all the successive stages of sacred orders, and installed as patriarch. His election was confirmed by two successive councils. The pope reinstated Ignatius, and excommunicated Photius, but the emperor, sustaining Photius, he retained possession, and retaliated on the pope by calling a new council. This council in 867 A. D. raised a controversy of doctrine and discipline between the churches of the east and west. The east withdrew from the west. The Emperor Michael being put to death, Photius was banished to Cyprus, and Ignatius was reinstated. The controversy went on, Photius was recalled, and he summoned a council which condemned the western church. Some time after this the separation was completed. He died about 891 A. D.

Pho'to-Engrav'ing is a process for the conversion of a photograph into an engraving, from which engraving prints may be taken by any good printing press. Such perfection has been reached in this art that photo-engravings have largely replaced wood-engravings for the purposes of book and newspaper illustration. One of the best, if not most of the processes in use to-day, will be found based upon discoveries made in the early part of the nineteenth century, that asphaltum, when it has been subjected to the action of light, is no longer soluble in its ordinary solvents. A plate therefore coated with asphaltum which has been exposed in the camera obscura to light and shade would possess a surface, part of which was soluble and part insoluble. By the application of biting acids, these plates are then chemically etched. This process is especially useful to reproduce line engravings or the pen-and-ink sketches used so freely in the daily papers and which are now rapidly produced by chemical processes. Many of the variations in the ordinary process are kept secret, and others could hardly be explained to any other than an expert.

Photog'raphy. The art of making pictures by the direct action of light on a sensitive surface dates from the beginning of the last century. The action of light on certain salts of silver was studied by Scheele, a Swedish chemist, in 1777, who laid the foundation for the work which followed. He found that certain of the salts were blackened by exposure to light, the effect being due largely to the blue and violet rays in the spectrum. It was an easy step to coat paper with this sensitive substance, and obtain impressions of leaves, ferns, and similar objects by the action of sunlight, but no way was known of rendering the pictures permanent, and they attracted no great amount of attention. In 1839, a Frenchman named Daguerre succeeded in producing a sensitive surface on a copper plate which was so rapidly affected by light that impressions could be made on it in the camera, which impressions could be made permanent. The process at once met with great favor, and, owing to its comparative cheapness, almost immediately supplanted miniature painting, which was then in vogue. The disadvantages of Daguerre's process were manifold. Very long exposures were required, a sitting was required for each picture, and the pictures had to be held in a certain light to be seen.

The next step was the invention of the collodion plate, which shortened the time of exposure, and furnished the means of producing any number of pictures from a single plate. It was necessary to use these plates in a wet condition, however, and their employment was consequently limited to the studio. The discovery of the dry plate, which is in use at the present time, was made about a quarter of a century ago, and was the means of bringing the art within the reach of everybody. Before the days of dry plates the photographer was obliged to carry about with him a portable dark room, for the plates had to be immersed in a bath of silver nitrate immediately before exposure, and the development could not be postponed a moment after exposure.

The present dry-plate process is essentially as follows. Glass plates are coated with a film of gelatine containing a mixture of bromide and iodide of silver. After exposure in the camera they are developed by means of suitable chemicals in a room illuminated only with red light. The action of the light on the plate is to start a reaction in the silver salt which requires the action of the developer to complete it. This reaction is the transformation of the white bromide of silver into black metallic silver. The plate after development consequently appears black wherever the light has acted on it, the resulting picture being called a negative, since the high lights are black, and the deep shadows white. After development the plate is transferred to a bath of hyposulphite of soda, which dissolves the unaffected silver salts leaving the gelatine quite transparent except for the black deposit which forms the picture. From this negative any number of pictures can be printed by exposing sheets of sensitized paper under it to the action of sunlight. The black deposit of sil-

ver in the film screens the paper from the blackening action of the light; consequently the resulting print is white in those places which, in the negative, are dark, and the picture is a positive. Modern plates are made so sensitive that it is possible to secure pictures of objects in sunlight in the $\frac{1}{1000}$ part of a second. The plates of Daguerre required an exposure of from five to fifteen minutes.

Since the introduction of these extremely sensitive plates photography has proved of the greatest aid in scientific investigations. In astronomy clusters of stars and nebulæ have been photographed, which no eye can see, even in the most powerful telescopes, for the photographic plate can be exposed for hours to the image, the action of the feeble light accumulating in the sensitive film, whereas in the eye, if the light is too feeble at once to affect the retina, prolonged gazing is wholly without effect.

By employing the light of the electric spark, rapidly moving objects can be photographed in as brief an interval as the millionth part of a second. In this way beautiful pictures of flying rifle balls, with the ripples and waves of air which accompany them, and the boiling wake which follows them, have been secured by Professor Boys of London. Professor Wood, of the University of Wisconsin, had secured in a similar manner pictures of sound waves in air, the image of the spherical wave of condensed air being impressed on the photographic plate by the light of an electric spark occurring at just the right moment. By means of cameras fitted with electric lights, which have been lowered into the sea, pictures of the ocean's bottom, with the sea plants and coral formations, have been taken. Swung from the tails of kites, cameras, operated by an electric current sent up the wire kite string, give us pictures of our surroundings as they appear from an elevation of a mile or two.

Book and magazine illustration is now done largely by photography, the old-fashioned woodcut having been driven out by the zinc plate, which is engraved or etched by a photographic process, giving an absolute fac-simile of the original drawing. One of the most remarkable developments within the last ten years has been the production of plates which are sensitive to all the colors of the spectrum. The ordinary commercial plates are sensitive only to the blue and violet parts of the spectrum, consequently red or yellow objects always come out black in the finished picture. Vogel, of Berlin, discovered, however, that if the plates were slightly stained with some aniline dye capable of absorbing the red and yellow light, they at once became sensitive to these colors, consequently such plates could be used for photographing colored objects, where it was essential that correct color values should be rendered. Plates are now made which will blacken in the light of the ordinary dark-room red lamp, almost as quickly as ordinary plates in candle light. Such plates are called arthochromatic plates, and they are used for photographing paintings and other colored objects, as well as in many of the processes of color photography. (See COLOR PHOTOGRAPHY.) Great improvements have also been made in photographic lenses within the past quarter of a century, the firm of Zeiss, in Jena, having been most active in the development of the modern photographic objective.

It is impossible to predict what the future has in store for photography. Still more sensitive plates would be of immense use, particularly in scientific photography, and it is not by any means impossible that some new discovery may give us at any time a plate ten times as rapid as the present one. What is most desired, however, is some satisfactory color process, which can hardly be expected until some one is fortunate to discover that unknown chemical which has the property of assuming a color similar in hue to the color of the light which illuminates it, and *retaining that color permanently*, a discovery of which there is no immediate promise.

COLOR PHOTOGRAPHY. — At the very beginning of the art of photography it was observed that traces of color sometimes appeared in the picture which bore some resemblance to the color of the light acting on the plate. Photographs of the solar spectrum were obtained in this way at the beginning of the last century, in which the colors were reproduced with more or less fidelity, but no method was discovered of rendering the colors permanent, and it is only within the last few years that satisfactory methods have been devised of producing colored pictures by the aid of photography. The methods in use at the present time may be divided into two classes, the direct, in which the color is produced by the action of the light, and the indirect, in which the color is applied subsequent to the taking of the picture, the photographic process being modified so as to cause the colors to distribute themselves properly in the finished picture.

The only successful process of the first class is that of Lippmann, the French physicist, whose method was carefully worked out by theory before a single experiment was tried. Lippmann's process is essentially as follows: A photographic plate is placed in a holder with the glass side toward the lens of the camera, and mercury is poured into the back of the holder, forming a metallic mirror in contact with the sensitive surface of the plate. The light after passing through the film is reflected back through the film in the opposite direction by the quicksilver mirror. A very remarkable thing now takes place. The reflected light waves from the mirror interfere with the oncoming waves, producing what are known as stationary waves in the sensitive film. Now while ordinary light waves

deposit the silver in the film in a solid mass, the stationary waves have the singular power of depositing it in exceedingly thin laminæ or films, each one thinner than the thinnest gold leaf. The thickness of the silver laminæ varies with the color of the light producing them, red light or long waves producing thicker films than blue light or short waves. Thin films we know show brilliant colors by reflected light, the commonest example being the soap bubble, and the silver laminæ in Lippmann's pictures show color in exactly the same way. The color of any part of the bubble depends on the thickness of the soap film, and in the same way the color of any portion of the photograph depends on the thickness of the silver films deposited by the light waves in that place. The curious thing about the process is that light of any given color will deposit films of just the right thickness to show the same color by reflected light after the plate is developed and fixed in the usual manner. And what is still more remarkable, this fact was recognized by the inventor of the process before any of his experimental work was done. The production of pictures by this method has thus far been confined to the laboratory, the conditions for success not yet being quite fully understood. Probably not more than half a dozen people in the world have succeeded in getting satisfactory results, owing to the experimental difficulties.

Of the indirect processes there are a number which have been developed far enough to be considered commercial successes. These processes are all based on the principle that any color can be imitated by a mixture of the three primary colors, red, green, and blue. The most beautiful results have been obtained by Mr. Ives of Philadelphia, one of the pioneers in this line of work, whose process consists, briefly, in taking three negatives of the subject through red, green, and blue glasses. These glasses prevent light of any other color than that which they are designed to transmit from getting at the plate; consequently each negative is a record of the distribution of one of the three primary colors in the original. From these negatives three transparencies on glass are printed, which, when thrown superimposed on a screen by means of three lanterns furnished with colored glasses similar to the ones used in taking the pictures, combine to form a very perfect reproduction of the original.

For exhibiting the pictures without the lanterns Mr. Ives has devised an instrument which he has named the "kromskop," in which the colored images are combined by reflectors. The pictures are stereoscopic as well, and the result is a reproduction so perfect that it is almost impossible to believe that we are not looking at the original object itself, for it stands out in full perspective with every color perfect.

Colored pictures can be produced from the three negatives taken through the colored glasses by making prints on thin glass plates coated with gelatine, staining them with aniline colors and then mounting them in superposition. The results obtained this way are, however, very inferior to those obtained by means of the kromskop, though they have the advantage of requiring no special instrument for their exhibition.

Another process, which was perfected independently and almost simultaneously by Dr. Joly of Edinburgh, and Mr. McDonough of Chicago, has been recently put upon a commercial basis. In this process the negative is taken on a plate in front of which is placed a screen ruled with very fine lines in red, green, and blue ink, the colors following each other in succession across the screen. This screen breaks up the picture into linear strips, any one of which may be regarded as a record of one of the three primary colors along that portion of the picture. From the negative obtained in this way a positive is printed on glass, which, when mounted in contact with a similar tri-color ruled screen, reproduces the colors of the original. The objection to this method is the obtrusiveness of the lines, especially when the pictures are projected. The colors are much weaker and less faithfully reproduced than by the kromskop method.

Still a third method has been recently devised by Professor Wood of the University of Wisconsin, in which the colors are produced by the diffraction of light. The peculiar advantage of this process is that the pictures may be duplicated by contact printing the same as ordinary pictures, but they require a special apparatus for their exhibition, and their preparation is a matter of considerable difficulty. This method, like that of Lippmann, has not yet got beyond the experimental stage. R. W. Wood.

Pho'tograv'ure. The expense of photogravure work greatly limits its use mostly to high-class bookwork. Large pictures, however, are produced by it, which rival the finest steel engraving in finish and delicacy. The photographs can be reproduced, but the process is largely employed for obtaining engravings, such as copies of celebrated pictures. The process is so nearly perfect that any touch of the painter's brush is clearly seen in the copy. We here give one of the methods. (See PHOTOGRAPHY for sensitized plate, negative, etc.) A gelatine relief is obtained by exposing bichromated gelatine to the action of light beneath a negative. The gelatine used is mixed with a certain quantity of black lead in a more or less granular form This causes the relief to have a surface which is granular in character, and also makes it a conducting one for electricity. Put now into an electrotype bath; it will soon be covered with a deposit of copper. A copper printing-plate is thus made, from which pictures are printed.

Pho'tophone, a curious instrument invented by Graham Bell in 1880. It is based upon the

fact, discovered by J. E. Mayhew in 1873, that the resistance of annealed selenium is less in sunlight than in the dark. Using a piece of thin silvered glass on a diaphragm, Bell was able, by means of the human voice, to deflect a pencil of sunlight so that, with each pulsation of the voice, a distant piece of selenium was alternately illuminated and left in the dark. This piece of selenium was in the circuit of a telephone receiver and a battery, so that at each illumination a sudden increase of current passed through the receiver, because the resistance of the selenium was diminished. One with his ear at the receiver, therefore, heard every pulsation of the voice that deflected the sunbeam upon the selenium. Such an instrument he called a "photophone."

Photosyntax (*fō'tō-sin'tăks*), a term formerly used for photosynthesis (which see).

Photosynthesis (*fō'tō-sin'thĕ-sis*), the process by which green plants make sugar, starch, and similar food. The materials used for this are carbon dioxide and water. The former is obtained chiefly (if not exclusively) by the leaves and twigs from the air, where it constitutes three parts in 10,000. It passes through the stomata (which see, also AĔRATION) by diffusion, dissolves in the water, saturating the cell walls, and so enters the cells. The organs by which the food is made are the minute green bodies, called chloroplasts, or chlorophyll bodies, which give the plant its color. They are composed of protoplasm, which holds a green dye, chlorophyll (which see), and are imbedded in the colorless protoplasm of those cells which lie near the surface of a plant. The chlorophyll absorbs some of the light, especially the red and yellow parts, and this energy is used (how is unknown) in the process of food-making. Even twilight (not moonlight) suffices for some photosynthesis; the amount of food made is proportional, other things being equal, to the brightness of the light. The details of the process are not known. Usually a sugar appears as the end product; this increases to a certain amount in the water of the cell; some of it is turned into starch, minute granules being formed in the chloroplasts. The food is constantly being carried away to places of use or storage. In daylight, food is usually produced more rapidly than it can be disposed of, but as photosynthesis ceases at night, the surplus is then removed.

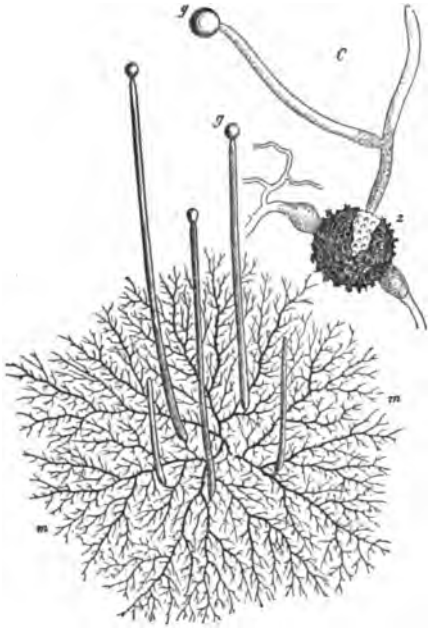
Phototaxis (*fō-tō-tăk'sis*) (in plants), the sensitiveness of an organism, free to move about, to unequal illumination (see IRRITABILITY), to which it responds by taking up a definite attitude with respect to the direction from which the brighter light acts. Only water plants are free to respond. Diatoms, desmids, some filamentous algæ, and zoospores of algæ and fungi show these reactions. Algal zoospores swim toward light and fungous zoospores swim away from it.

Phren'ology. In popular language, phrenology may be defined as the theory of mental philosophy based on the size, or the relative size, of the different parts of the brain. It claims that we can localize the different parts of the brain which give rise to different mental functions. Phrenologists make a map of the cranium, writing on one division, self-esteem; on another, wit, and so on. Examining your head, the phrenologist will put his finger on one point and say, "This man has a large development of self-esteem." Moving his hand to another bump, "This man is lacking in veneration," or "He has a great power of language," or "He has to try hard to give exact statements," and so on. The cultivated phrenologist thus goes through all the divisions of mental and moral qualities, finding a local boundary in the brain for each. In Britain, Gall, Spurgheim, and George and Andrew Combe, may be mentioned as representative phrenologists. In America, the more noted are Dr. Charles Caldwell, the brothers Fowler, and Wells.

Phryg'ia, an ancient country of Asia Minor, whose boundaries varied at different periods. It is supposed that at one time Phrygia included most of the peninsula. In general, it was a high plateau which afforded pasturage for flocks. Gold was found in the mountains and streams. Vines were cultivated in some districts, and Phrygia marble was greatly prized. Phyrgia was conquered by Crœsus in the 6th century, and he in turn was conquered by the Persians in 549. The influence of the Phrygian religion is traced in Greek mythology.

Phycomycetes (*fī'kō-mī-sē'tēz*), plants forming one of the great groups of fungi, which is distinguished by being more like the algæ in structure and reproductive habits than any of the fungus groups. The name means "alga-like fungi." The mycelium is composed of coenocytic threads or hyphæ, that is, filaments which contain no partitions. (See COENOCYTE). It seems to be more than probable that the group has been derived from the green algæ. Prominent members of the group are as follows: Saprolegnia forms are known as "water moulds," because they live upon the dead bodies of water plants and animals, sometimes attacking living fish, one species being very destructive to fish in hatcheries. It is interesting to note that this group of Fungi has retained the aquatic habit of the algæ. As a consequence, its asexual spores are ciliated and have the power of swimming. Another feature of the water-moulds is that the oogonium sometimes forms several eggs, and that frequently the eggs form new plants without any fertilization, being an illustration of the habit called parthenogenesis (which see). The mucor forms are well represented by the "black moulds," which form white furry growths on damp bread, manure heaps, etc. From the pros-

trate mycelium numerous erect branches arise, each bearing at its summit a globular sporangium containing numerous asexual



Mould, showing mycelium (*m*), young sporangia (*g*), and fertilized egg (*z*).

spores. The mucors are isogamous (which see). The peronospora forms are the "downy mildews" which are very common internal parasites on seed plants, one of the most common kinds attacking grape leaves. The presence of the parasite is made known by discolored and finally deadened spots on the leaves where the tissues have been killed. The spore-bearing branches rise above the surface of the leaf, and many of them arising near together, they form little velvety patches suggesting the name downy mildew. These forms are heterogamous. See HETEROGAMY.

Phyl'loclad (in plants). See CLADOPHYLL.

Phyllodia (*fi-lō'di-a*), (in plants), petioles which resemble leaves in form and function. The most conspicuous display of phyllodia is among the acacias, especially those of Australia. The normal leaves are pinnately compound, but for the most part they do not develop, the petiole becoming flat and doing the leaf work.

Phyllotaxy (*fil'lo-tăk'sy*). The name literally means "leaf arrangement," and has to do with the distribution of leaves upon the stem and the laws which govern it. In general, there are two types of leaf arrangement: that in which the two or more leaves are developed at the same node, giving rise to what is called the "verticillate" or "cyclic" arrangement; and that in which but a single leaf occurs at each node, giving rise to the "alternate" or "spiral" arrangement. In the case of the spiral arrangement, some relations have been discovered which seem to be more curious than important. In the simplest cases, the leaves occur in two vertical rows, the angular divergence between any two successive leaves being one-half of the circumference of the stem, or 180°. This type of phyllotaxy is designated by the fraction $\frac{1}{2}$, which shows the angular divergence, while the denominator indicates the number of vertical ranks. In the next higher series, the leaves occur in three rows, the angular divergence between successive leaves being one-third the circumference, or 120°. The fraction $\frac{1}{3}$ designates this arrangement. The next higher arrangement, is the one in which there are five vertical rows, but in order to reach a leaf standing directly over the one started from, a spiral is traced twice around the stem. The angular divergence between two successive leaves, therefore, is two-fifths of the circumference, or 144°, and this arrangement is designated by the fraction $\frac{2}{5}$. It has been found that any fraction may be derived by adding the numerators and denominators of the two preceding fractions. For example, the next higher arrangement would be $\frac{3}{8}$, which means that the angular divergence is three-eighths the circumference of the stem, that is, eight leaves are passed before one is reached standing directly over the one started from, and in finding the eighth leaf a spiral has been traced three times around the stem. Such high orders of arrangement, as $\frac{5}{13}$, $\frac{8}{21}$, etc., are displayed in pine cones.

Phyllox'era. Se GRAPE PHYLLOXERA.

Phys'ical Sci'ence, a term used in contrast with *natural* science to denote all those sciences which deal especially with inanimate matter. This distinction between *natural* and *physical* sciences, which was explicitly suggested by Maxwell, would reserve natural science for the subjects considered under the heads of Zoology, Botany, Paleontology, Physiology, Anatomy, Psychology, Anthropology, Ethnology, etc., all of which deal with life in some of its aspects; while among the physical sciences would be included Physics, Chemistry, Mineralogy, Geology, Astronomy, etc. This classification would make Biology the fundamental science of the natural group and Physics the foundation of the physical group. Physical Science may be defined, therefore, as that branch of learning which deals especially with energy and with inanimate matter.

It should be borne in mind by the student that *physical* and *natural* originally meant the same thing, the only difference being that the former is of Greek origin, while the latter comes from the Latin. Accordingly, we still find a great diversity of usage. Thus Lord Kelvin still speaks of a certain physicist as a "distinguished naturalist." The distinction

suggested by Maxwell is, however, being rapidly adopted.

The unprecedented growth of physical science during the 19th century has had the effect of enormously subdividing the subject. Thus astronomy which is, in fact, the simplest branch of physics requires a peculiar set of instruments for its pursuit and is, therefore, no longer studied under the head of physics. The same is true of chemistry, which is the physics of the molecule: it has become a large subject requiring a special equipment, and is now a science quite separate from physics. Such was, however, not the case when Robert Boyle studied physics and chemistry. In like manner, geology is the *physics of the Earth's Crust;* but it must be studied afield as well as in a special laboratory and is, hence, a separate and very important science. Mineralogy also deals with the physics of a special group of bodies. But these bodies are so vast in number and so enormously important in commerce that they must be studied elaborately and carefully under a special head, and with a special equipment.

Turning now from the *pure* physical sciences to the *applied* physical sciences, we find them grouped under the general head of *engineering*, which in turn has already been extensively subdivided. It is the rapid advance in physical science which has made possible the rapid improvements in modern civilization, somewhat in the same manner that the rapid advances in natural science have made possible a more powerful and beneficent science of medicine and have introduced into modern thought the controlling principle of evolution.

Physics (*fĭz'ĭks*), in its broad sense, is that science which deals with the properties of matter and of energy. In its narrow sense, physics is defined in such a way as to exclude those properties of matter which depend upon its composition (referring them to chemistry), and those properties of matter which are exhibited only in living beings (referring them to biology).

For many years, however, there has ceased to be any sharp distinction between physics and chemistry, witness the new sciences, physical chemistry and electro chemistry.

Popularly defined, physics is made up of the sciences of mechanics, heat, light, sound, electricity, and magnetism. A sounder view is that which regards physics as the application of dynamics to the phenomena of sound, heat, light, electricity, and magnetism.

The subject of physics in this work has been treated under separate heads, accordingly see ARTICLES, DYNAMICS, ACOUSTICS, HEAT, LIGHT, ELECTRICITY, MAGNETISM, ELASTICITY.

Physiog'raphy. SCOPE OF THE SUBJECT.—This term has but recently come into use, and its meaning is not yet clearly and uniformly defined. In England, physiography is regarded as the introduction to physical science in general. It is made to include the elements of physics, chemistry, astronomy, physical geography, and geology, and sometimes even certain phases of botany and zoology. In America, the term has a somewhat different meaning. It is sometimes used as a synonym for physical geography, and it is sometimes defined as the science which describes and explains the physical features of the earth's surface. In this latter sense it is the correlative of meteorology, which treats of the atmosphere, and of oceanography, which treats of the oceans. According to early usage, the term physical geography meant a description of the earth's physical features; but physiography does not content itself with a mere description of physical features. It attempts also to explain how existing physical features originated. This indeed is the fundamental distinction between physiography, as the term is commonly used in America, and that part of physical geography which deals with the physical features of the earth's surface. In its attempt to explain the origin of the present features of the earth's surface, physiography necessarily draws, to some extent, on the past history of the earth; that is, on geology. Between physiography and geology, therefore, there is no sharp line of division. The present features of the earth are the surface expression of the geological processes which have operated in the past. The relation of physiography to geology may be likened to the relation of political geography to history. Political geography is an expression, in one form, of history. The political geography of all stages of history would be, from one point of view, a summary of history. Similarly, if the physiography of each stage of the earth's history were known, this knowledge would give us, from one point of view, the complete history of the earth.

The atmosphere is as much a part of the earth as the rocks are. The study of the atmosphere is meteorology, but, even in its narrowest meaning, physiography includes the consideration of the atmospheric forces and processes which have shaped, or helped to shape, the present surface of the land. This includes the movements of the air (winds), the moisture of the air, especially precipitation, the changes of temperature, and the chemical changes effected, directly or indirectly, through the influence of the atmosphere. While meteorology includes the study of atmospheric movements as such, physiography, in its narrower sense, includes only the effects of those movements on that part of the earth which lies below the atmosphere. The ocean, likewise, is a part of the earth. The science which deals with the ocean, as such, is oceanography; but the consideration of the ocean as a part of the earth falls within the province of geology, while a consideration of the effects of oceanic activities which modify the surface of the solid part of the earth falls within the scope of physiography. Thus, the effects

of rivers, waves, currents, etc., on the configuration of the solid part of the earth fall within the province of physiography. Physiography, therefore, concerns itself primarily with the topographic results of geologic processes. It is a special phase of geology. Since the geological processes which have left pronounced topographic results are the processes of late geological time, physiography has to do with but a brief part of the earth's history.

PHYSIOGRAPHIC PROCESSES. — Powell long ago grouped all processes that work on the earth's surface into three classes: (1) The processes of diastrophism; (2) the processes of vulcanism, and (3) the processes of gradation. *Diastrophism* includes the up and down movements of the earth's crust, movements which, however gentle and slow, are continually in progress. *Vulcanism* includes all processes connected with volcanoes. *Gradation* includes all processes by which material is shifted from one point on the earth's surface to another. The centers of diastrophic and volcanic activity are beneath the surface. The processes of gradation are in operation on the surface, chiefly at the plane of contact between atmosphere and land, and between water and the solid part of the earth beneath it. The transfer of material in gradation is usually from higher to lower levels. Thus rivers carry debris from land to sea. They *degrade* the land, and the material, deposited in the sea, *aggrades* its bottom. Glaciers, likewise, carry material from higher levels to lower. They degrade the places where they gather debris, and aggrade the places where they leave it. The degradation of one place generally involves the aggradation of another. The sand and dust blown by the wind constitute a partial exception to the rule that the materials shifted about on the earth's surface are transferred from higher to lower levels.

LAND AND WATER AREAS. — The greatest features of the earth's crust are the elevations known as continents, in contrast with the depressions known as ocean basins. The sharp topographic division-line between continents and ocean basins does not correspond with the borders of the continental land areas. For a distance about the continental lands the water is very shallow. There is then a sudden descent of the bottom to much greater depths. The area beneath the shallow water is the *continental shelf*. Its outer border is usually about 100 fathoms below the level of the sea. From the physiographic point of view, the outer edge of the continental shelf is the border of the continent. While the explanation of the existence of continents and ocean basins is a problem of physiography, it is an unsolved problem. No assertion can be made at the present time as to how these greatest of physical features originated. The continents have sometimes been looked on as uplifted portions of the earth's crust; but it would perhaps be quite as near the truth to consider the ocean basins as depressed portions. It is, however, far from certain that the surface of the solid part of the earth was ever regular. If the continents were lifted up, or if they were left up as the result of the sinking of the ocean basins, they are the result of diastrophism. If this was not their origin, they probably came into existence when the earth was in process of formation, whatever that process was. Smaller land masses, that is, islands, have originated in various ways. Some are diastrophic, some are gradational (aggradational), and many are volcanic.

Physiography has to do with both the horizontal and vertical configuration of land areas and sea. The horizontal configuration of the one is the counterpart of the horizontal configuration of the other; but the vertical configuration of the one stands in no necessary relation to that of the other.

THE HORIZONTAL CONFIGURATION OF LAND AREAS. — It is the province of physiography to define, classify, and explain the origin of all sorts of horizontal irregularities of land areas. Among the horizontal irregularities of the land are peninsulas, capes, etc., or land masses projecting into the sea. Among the horizontal irregularities of the ocean are gulfs, bays, etc., or bodies of water projecting into the land. The sizes, positions, and shapes of these irregularities are readily expressed on maps. Not so their origin. They have, indeed, originated in many different ways. For example, the uplift of an area of sea bottom along a line at right angles to the coast of a continent, would give rise to a peninsula, like Florida. The uplift of two such peninsulas near each other might leave a gulf or bay between them. Again, the sinking of a coast allows the sea to invade the lower ends of the river valleys, forming bays, such as Delaware bay and Chesapeake bay. When the sea converts the lower ends of adjacent valleys into bays, it leaves a peninsula between. Peninsulas and bays formed in this way are the results of diastrophism. Small peninsulas or capes, like Cape May, may be built by deposits of sand and gravel made by waves and shore currents. They are the result of gradation, in this case of aggradation. Glaciers moving down valleys to the sea, as in high latitudes, may gouge out the lower ends of the valleys through which they pass, cutting them down far below sea level. When the ice melts, deep, narrow bays or *fiords*, like those of Greenland, Norway, Alaska, etc., are the result. Such bays are a result of gradation, in this case degradation. Volcanic activity on a coast line may result in extending the land, making a cape, or in destroying land which previously existed, leaving a bay. Thus horizontal irregularities may arise by vulcanism, as well as by diastrophism and gradation. Horizontal irregularities arise in many ways not here enumerated, especially by various processes of gradation; but the fore-

going illustrations will suffice to show that horizontal irregularities may result from any one of the three sets of processes referred to above. The horizontal configuration of a land area may be altered by animal or plant life, as when coral reefs are constructed, or when mangrove trees invade the water, extending the land. These may be looked on as special cases of aggradation.

Relief Features of the First Order. — Physiography has also to do with the vertical configuration of the land. The great relief types are three: Plains, plateaus, and mountains.

Plains are relatively low areas of considerable extent, with surfaces which are not notably rough. *Plateaus* are similar tracts of greater altitude, and which stand up more or less prominently above their surroundings on one or more sides. *Mountains* usually have less areal extent, and stand up more conspicuously above their surroundings. They generally have somewhat narrow summits and steep slopes.

As topographic features, plateaus and plains may be said to differ from one another chiefly in elevation; yet there is no specific elevation above which land may not rise, and remain a plain. Formerly, plains were often defined as lands below 1,000 feet in elevation; but this arbitrary definition has no warrant in nature or in usage. The fact is, that plains often grade into plateaus, and that there is no sharp line of demarkation or basis of separation which is uniformly applicable. An extensive tract of land, 500 feet above the sea, would probably be called a plain if it were surrounded, or nearly surrounded, by higher land, or if it were bordered by notably high land on one side, and descended gradually to much lower levels on others. On the other hand, a tract of land, 500 feet above the sea, would probably be called a plateau if it were bordered on one or more sides by a tract of considerable extent, which had an elevation of but 100 or 200 feet, particularly if the descent to the lower level were abrupt. Extensive areas 1,000 feet, or even considerably more, above the sea, would probably be called plains rather than plateaus, if they were surrounded, or largely surrounded, by higher lands, while they would be called plateaus if they stood up distinctly above their surroundings. Thus parts of the *plains* of the Mississippi basin are higher than parts of the Piedmont *plateau* lying east of the Appalachian mountains. It is, therefore, a question of surroundings and relations, rather than actual elevation above the sea, which determines whether a tract shall be called a plain or a plateau.

A plateau may be bordered by slopes which descend abruptly on all sides, or by slopes which descend gently on all sides; or a plateau may descend abruptly or gently on one side, and be bordered by a higher plateau or by a mountain range on another. In the latter case, the rise to the higher slopes may be abrupt or gentle. If abrupt, the separation of plateau and mountain is distinct; if gentle, the one grades into the other. If a high plateau becomes narrow and long, and if it descends in all directions, or on both sides, it may approach a mountain range in form.

Mountains are not more sharply defined than plains and plateaus. The term mountain implies notable elevation, but a mountain is not necessarily higher than a plateau. Thus the plateau of Thibet is much higher than any part of the Appalachian mountain system. The term mountain implies (1) a considerable elevation above surroundings, and (2) crests of limited area. An isolated elevation 1,000 feet above its surroundings, rising abruptly above a low flat plain, would doubtless be called a mountain, though an elevation, of the same height, with gentler slopes, on a rolling plateau, might not be.

It is the task of physiography to describe the forms and relations of plains, plateaus, and mountains, to explain how they came into existence, and how they came to assume the forms which they now have. Some plains originated by diastrophism, as by the elevation of shallow sea bottom enough to convert it into land; others are the result of aggradation, the building up of sea-bottom slightly above the level of the sea; others are the result of the degradation of mountains and plateaus; and still others owe their origin to the combined action of diastrophic and gradational forces. Subsequent to the origin of plains, their surfaces have been modified by rain, rivers, winds, glaciers, etc. It is the task of physiography to determine the nature and the extent of the changes which these several agencies have effected. Plateaus are the result either of diastrophism or vulcanism, or both. They are plains elevated to the condition of plateaus, or, less commonly, they are built up by lava flows. After they come into existence, plateaus are subject to the same changes as plains. Mountains have originated in various ways: by diastrophism, as in the case of mountains formed by the upfolding of the superficial strata of the earth's crust, or by the up-thrust of blocks of the earth's crust; by volcanoes, as in the case of volcanic peaks; and by gradation. The origin of mountains by gradation will be referred to later. Like plains and plateaus, mountains are modified by wind and water and air, after they are formed. Physiography essays to explain how they originated, and how far their present forms are the result of original uplift or upbuilding, and how far the result of subsequent gradation.

Minor Relief Features. — The great relief forms, plains, plateaus, and mountains, are affected by numerous smaller relief features. Thus, a plain or a plateau may be affected by depressions (valleys) cut out by streams. Between the valleys, elevations remain. If

the elevations be long and narrow, they are *ridges;* if short, *hills.* The valleys are *made;* the ridges and hills are *left.* As a result of the excavation of valleys, plains may be far from flat. Generally speaking, the valleys are deep in proportion as the land is high. The valleys of plateaus are, on the whole, deeper than those of plains, and the ridges and hills between them are therefore higher. If the ridges or hills be very high, they may be called mountains. For example, the Catskill mountains are simply the big hills left in the erosion of the plateau which once existed where the mountains now are. The depressions between the mountainous hills have been worn out by running water. It is thus that mountains originate as the result of gradational processes, operating on plateaus. Special names are given to special forms of hills or mountains, developed by erosion. Here belong *buttes*, large, flat-topped, high hills developed by erosion in arid regions; *mesas*, which are more extensive remnants of plateaus, etc.

Along valley bottoms, whether the valleys are in plains, plateaus, or mountains, narrow *alluvial* plains are often developed. So, too, about the borders of lakes, whether in plains, plateaus, or mountains, low, flat *lacustrine* plains of limited extent are made, either as the result of deposition in the lake, or as the result of the lowering of its level, or both. Lacustrine and alluvial plains are minor, secondary features, in relief forms of the first order. Small plains are also developed in other ways. Along streams and lakes, or along the ocean, terraces are often developed. They represent other minor topographic forms developed in plains, plateaus, or mountains.

Between highlands and lowlands there are always *slopes.* The slopes between mountains and plateaus are parts of the mountains and plateaus, respectively. So, too, the slopes between the surface of a plateau and the bottom of a valley cut in it are parts both of the plateau and of the valley. Yet slopes constitute a somewhat distinct class of topographic forms. If slopes are very steep, and especially if they are steep and high, they are called *cliffs.* Cliffs occur along sea and lake shores, as well as along valleys. It is within the province of physiography to explain how these secondary and minor features, such as alluvial plains, lacustrine plains, terraces, slopes, cliffs, etc., arose, and how their individual peculiarities of form were developed.

Another topographic form is the *basin.* Basins, like most topographic types, are of various sorts. Some of them are large and some are small. They may affect the surfaces of plains or of plateaus, or they may occur among mountains. Some of them have outlets, and some have not. Those which have not may give rise to lakes, ponds, etc. Ponds and lakes may have outlets, but below the level of the outlet there is a basin which has no outlet, else there would be no lake or pond. Other so-called basins are inclosed on three sides and open on the fourth, or at least at some one point. It is customary to speak of the great depression between the Appalachian mountains on the east, the Rockies on the west, and the Height of Land on the north, as the Mississippi basin, although it is by no means completely inclosed by high land. It is the function of physiography to define the various types of basins, and to explain their modes of origin and their individual characteristics.

CONFIGURATION OF THE SEA BOTTOM.—The configuration of the sea bottom also falls within the province of physiography; and, while the sea bottom is less familiar than the land, its general features are known. It is known, for example, that there are great areas of the sea bottom elevated above their surroundings. Such areas are comparable, in some sense, to the plateaus on land. There are great areas where the ocean bed is depressed, relative to the areas just referred to. Such areas are comparable to the plains of the land. There are other depressions in the ocean bed, more limited in area, which are comparable to basins on the land, though some of them are much larger, both in area and depth, than the inclosed basins on the land. Many parts of the ocean basin have been affected by vulcanism. Volcanic peaks are, on the whole, more notable features of the ocean bottom than of the land. In its fundamental features, or features of the first order, therefore, the ocean bed has some likeness to the land. But gradational, and especially degradational agencies, are hardly operative on the ocean bottom, except in very shallow water. Since it is degradational agencies which produce the most notable secondary features of land surfaces, and since these agencies are little operative in the sea, the sea bottom is, in general, without the hills the ridges, the mountain peaks due to erosion, the valleys, valley plains, and terraces, which abound on the land. These physiographic forms are sometimes found on the sea bottom, and the areas where they occur are thought to have been land at one time, though now submerged. On the other hand, the shallow sea bottom is affected by bars, reefs, etc., built by waves and shore currents, and by coral polyps. Reefs are not formed on land, and only occur there, when an area of sea bottom is elevated to the estate of land.

Physiol'ogy. Anatomy shows us that animals and plants are wonderfully constructed. But after we understand their architecture, and even their minute structure, the questions remain: What are all the organs and tissues for, and what takes place within the parts that are actually alive? Physiology attempts to answer questions of this nature. It therefore stands in contrast with anatomy and is supplementary to it. The activities of the body are varied and depend on life for their manifestation — they may be called vital activities. Physiology embraces a study of them all. This subject began to attract the attention of the ancient medical men, who wished to fathom the activities of the body in order to heal it in disease. But it is such a difficult thing to begin to comprehend the activities of life, that even the simpler relationships were imperfectly understood, and they resorted to mystical explanations. They spoke of spirits and humors in the body as causing the various changes. The arteries were supposed to carry air, the veins only blood, and nothing was known of the circulation. In these early days, also, anatomy, physiology, and medicine were all united into a poorly digested mass of facts and fancies. This state of affairs lasted till the 16th century and then the awakening came through the efforts of gifted men endued with the spirit of independent investigation. The advances made depended upon the work or leadership of these men, and certain periods of especial importance should be pointed out.

First is the period of Harvey (1578–1657). In his time the old idea of spirits and humors was giving way, but there was still much vagueness about the relationships and activities of the body. He helped to illuminate the subject by showing a connection between arteries and veins and demonstrating the circulation of the blood. Harvey did not see the blood passing through the capillaries from arteries to veins, but his reasoning was unassailable that such a connection must exist, and that the blood made a complete circulation. He gave this conclusion in his medical lectures as early as 1619, but did not publish his views until 1628. It was reserved for Malpighi, in 1661, actually to see the circulation through capillaries under the microscope, and for Leeuwenhoek, in 1669 and later years, greatly to extend the observations. The next great period was marked by the work of Haller (1708–77), who made physiology an independent subject. It had previously been united with anatomy and medicine; he made it a subject to be studied for its own sake. The period that marks the beginning of modern physiology came next, and was due to the genius and force of Johannes Müller (1801–58). He studied physiology so broadly that he made it comparative. He used every means at his command — experiment, observations on simpler animals, the microscope, the discoveries in physics, chemistry, and psychology. He made physiology systematic and broadly comparative, and gained for himself the title of the "greatest physiologist of modern times." Not only did he do important work himself, but, as professor of physiology at Berlin, he trained many talented young men, among whom were Ludwig (1816–95), Du Bois-Reymond (1818–96), and Helmholtz (1821–94). Thus his influence reached to the present time and affected recent physiology. With these distinguished German physiologists should be mentioned Claude Bernard (1813–78) of France, and Sir Michael Foster of England (1836–).

Physiology has broadened and deepened until it includes the vital activities of the entire animal and vegetable worlds. Every action or function dependent upon life is embraced by it. These are so varied that they must be reduced to order and system, and, when that has been done, we observe that all the functions may be grouped under three great headings. Those concerned with Nutrition, those connected with Relation, and those pertaining to Reproduction. The division nutrition embraces every activity concerned in nourishing the body. It must include a discussion of the blood, its structure, circulation, and changes. All about the heart and the influences which affect it. The digestive system, the kinds of food, the nature of digestion, the absorption of the food into the circulation, the secretion of substances like the digestive juices and other forms of secretions in the body, the action of the liver, pancreas, and similar organs. Respiration is connected with nutrition, because the oxygen brought in is used in all processes of the body, and the removal of the carbon dioxide (Co_2) is an aid to nutrition. One must, therefore, learn all about the breathing organs, and the nature of the exchanges between the blood, the air, and the tissues. The living protoplasm of the body is continually undergoing disintegration, it breaks into carbon dioxide, water, and nitrogenous compounds. In order that nutrition may be effectively carried on these waste products must be removed. This topic includes the action of the kidneys, the lungs, and the skin. The varied chemical changes in assimilating the food, and the reverse set of changes resulting in the liberation of energy must be considered under the heading Nutrition.

Another great division of physiology deals with the means by which an animal or plant is brought into proper relation with its surroundings. This includes, in higher animals, the action of the nervous system and sense-organs, as well as control of the nervous system over the organs. The muscles and organs of protection are also involved in bringing about a harmonious relation between surroundings and the animal. Finally, repro-

duction refers to the preservation of the race, and is more for the benefit of the race, generally speaking, than for the individual.

A study of all these varied activities is physiology. Reference must be made to text-books and manuals for further consideration. It is a common fault with our elementary physiologies, to go too much into the discussion of the effects of alcohol and narcotics. The importance of such a discussion is unquestioned, but the facts of physiology and hygiene should stand out in unrivaled prominence. Among the smaller texts, Huxley's *Lessons in Elementary Physiology* (new edition, 1900), is the most lucid statement of the facts of physiology yet presented. Among the best books of greater extent may be mentioned the following: Fosters' *Text-book of Physiology* (4 vols., fifth edition, 1891–93); Stewart's *Manual of Physiology* (third edition, 1898); Kirke's *Handbook of Physiology* (the latest edition); Howell's *An American Text-book of Physiology* (1896); Verworn's *General Physiology* (1899); Martin's *The Human Body;* Hall's *Text-book of Physiology* (1899). See BLOOD, CIRCULATION, HEART, LIVER, MUSCLE, NERVES, RESPIRATION, etc. WM. A. LOCY.

Physiol'ogy (of plants), that branch of science which treats of the activities of living beings. These are essentially the same in plants as in animals, but are often simpler. Plant physiology is concerned with the action of the plant body as a whole, the part which each of its organs takes, and the ways in which they are adjusted to one another and to the external world. (See also ECOLOGY.) The work of a particular part, or organ, is called its function. The important general functions of plants are absorption, water transfer, transpiration, nutrition (in the narrower sense) including digestion, photosynthesis, and assimilation, secretion, respiration, growth, and movement. (See these topics; also IRRITABILITY.) In the higher plants, the root is an absorbing organ for water, mineral salts, and such organic matter as is soluble in water; the root, stem, and leaves are furnished with strands of tissues along which water and foods can travel readily; the leaves and the surface of the stem, at least when young, are organs of absorption and evolution of the gases carbon dioxide and oxygen; they also lose water by evaporation, and are most important as organs for the making of carbohydrate foods. All these functions, however, may go on in a single cell of one of the simplest plants.

Pian'oforte, a stringed musical instrument played by keys, developed out of the clavichord and harpsichord. It differs from these chiefly in the introduction of hammers with which to put the strings in vibration, connected with the keys by a mechanism that enables the player to modify at will the intensity of the sounds. It is this peculiarity to which the name is due, *piano* being the Italian for soft, and *forte* for loud. The strings are stretched across a compound frame of wood and metal, composed of bars, rods, and strengtheners of various kinds. This framework includes a wooden sound-board. The mechanism by which hammers are connected with the keys is called the *action* of the instrument. The duration of a note is regulated by the damper. This consists of a piece of leather, resting on the top of the string, and connected with the back part of the key by a vertical wire. When a key is pressed down, its damper is raised off the string so as to allow the sound to be clear and open; but when the finger is taken from the key, the damper wire falls immediately, and the damper presses down on the string, muffling and stopping the vibration. One of the pedals is called the loud one, the other the soft one. Great difference of detail exists in the "actions" of different makes, but in all are the same essential parts. See Hopkins' *Musical Instruments.*

Piaster (*pī-ăs'ter*), "a plaster," in the Latin; in the Romance languages, "any thing spread out," "a plate," "a coin." The word is applied to an old Spanish coin, worth not quite $1.00 of United States money. It was divided into eight reals, and hence was called "a piece of eight." The Italian piaster is an imitation of, and is nearly equal to, the Spanish piaster in value. The Turkish piaster is worth about four cents of United States money.

Pibroch (*pē'brŏk*), a form of bagpipe music, generally of a warlike character. The rhythm is irregular and difficult for a stranger to follow; but played by a good piper it has a powerful effect.

Picayune (*pĭk'ā-ūn'*), a name derived from the Carib language, and used in Louisiana for a small coin worth six and one-quarter cents, current in the United States before 1857, and known by various names in different states — fourpence, fippence, fip, and sixpence.

Pick'erel. See PIKE.

Pick'ering, Edward Charles, a distinguished American astronomer, born at Boston, July 19, 1846; educated at Harvard, where he graduated from the Lawrence Scientific school in 1865. He immediately accepted an instructorship in physics at the Massachusetts Institute of Technology, where he founded the first physical laboratory in America, and where he remained until 1877, when he went to Harvard as professor of astronomy and director of the observatory, a position which he has filled with increasing distinction during a quarter of a century. Professor Pickering's most original work is perhaps along the line of stellar photometry and stellar spectroscopy. But the conception and skillful direction of the many lines of work carried on at the Harvard observatory,

as well as the building up of the observatory itself, must always remain a great service to science and a monument to Professor Pickering. He is a member of the National Academy of Science, the author of several important volumes, and the editor of the *Harvard Annals*, an invaluable series of astronomical reports.

Pick'ett, George Edward, an American soldier who won world-wide distinction in the Confederate service at Gettysburg, where he made one of the most gallant and desperate charges ever known in the history of war. He was born at Richmond, Va., Jan. 25, 1825, and graduated at West Point in time to enter the army as a second-lieutenant during the war with Mexico. He was brevetted first-lieutenant, and afterward captain, for conspicuous bravery in Mexico. He served for the most part on the frontier between 1848 and 1861. At the outbreak of the Civil war, he resigned his commission as captain in the army of the United States and entered the Confederate service as a colonel. He became a major-general in 1862. He was engaged in several desperate battles under Lee, but won special distinction as the leader of the assaulting column, July 3, 1863, upon which the fate of the Confederacy hung. The point reached by his troops in this charge, and from which they were at last driven back, is marked upon the field of Gettysburg to-day by a granite monument. In the campaign of 1864–65, he made the final stand at Five Forks, and he prevented the capture of Petersburg by General Butler. At the close of the war he returned to Richmond and engaged in life-insurance business, dying at Norfolk, Va., July 30, 1875.

GEN. G. E. PICKETT.

Picts, a people, who from 296–844 A. D., inhabited eastern Scotland from the Forth to the Pentland Firth. Sometimes we find them called by the name Cruthnig. The first mention of them in Roman annals is in connection with campaigns in Britain in 296 and 306 A. D. The first mention of the Scots is made in connection with their being united with the Picts in harassing the Romans in 360 A. D. The Pictish kingdom was overthrown about 850 A. D., when the Scots became the predominant race. It is undecided what was the language the Picts spoke, though the prevailing opinion is that they were a Celtic race. See Skene's *Chronicles of the Picts and Scots.*

Pied'mont, the northwest part of the kingdom of Italy, comprising the modern provinces of Turin, Alessandria, Cuneo, and Novara. Area, 11,340 square miles; population 3,417,047. Much of its land is reclaimed by irrigation, and made highly productive. The system of irrigation is well-nigh perfect. It is watered by the upper Po. The country is rich in Waldensian memories.

Pierce, Franklin, fourteenth President of the United States, was born in New Hampshire, Nov. 23, 1804. He early came into political prominence in his native state. In 1837, he was elected to the United States senate, of which he was the youngest member. In 1842, he resigned his seat. He was a Democrat of the Jackson school, and a zealous advocate for the admission of Texas, with or without slavery. He volunteered as a private in the Mexican war, but the President made him a brigadier-general. In 1852, he received the Democratic nomination for the presidency and obtained the electoral votes of all the states, save Vermont, Massachusetts, Tennessee, and Kentucky. During his administration, the Missouri Compromise was repealed by the passage of the Kansas-Nebraska bill. At the close of his administration, he spent three years in Europe; returned home to Concord, but took no part in politics. He died at Concord, N.H., Oct. 8, 1869.

FRANKLIN PIERCE.

Pierre, the capital of South Dakota, is situated near the site of old Fort Pierre, in about the center of the state. The fort was founded in 1829, and was named after one of its early fur traders. The present population of Pierre is 2,306.

Pierre'pont, Edwards, American lawyer and diplomat, was born at New Haven, Conn., in 1817; and died at New York, March 6, 1892. As attorney-general of the United States, he conducted the trial of Surratt, for being an accomplice in the murder of President Lincoln. In 1876, he was sent as minister to Germany. As a jurist he had a wide reputation, and European governments were influenced by his writings upon international law.

Pig. See SWINE.

Pigeon (*pij'un*), a name for members of the dove family. There are about 300 species of pigeons all over the world, being most abundant in the East Indies. Only two are found in the Eastern United States — the wild pigeon, and the turtle dove. The wild pigeon, or passenger pigeon, is now exceedingly rare. It was formerly very abundant, perching in the forests in such numbers as to

break limbs of trees, and covering a large territory in their daily flight in search of food. During migration, they flew in such large flocks that it would sometimes require days for them to pass a particular point. They were nearly exterminated by wholesale slaughter. It is a bird about seventeen inches long, with large wings, and a long pointed tail. The male is bluish above, purple brownish-red below, more violet behind, with a black bill and yellow feet. It depended largely upon acorns and beechnuts for food, with occasional feasts on grain and berries. The turtle dove, or mourning dove, is still quite common. The long, soft, mournful note of the male during the nesting season, is known to nearly everyone in the United States. It is a smaller bird than the passenger pigeon, being about 11¾ inches long. The upper parts are olive grayish brown, the neck iridescent, the breast pinkish, and the belly buff; the outer tail feathers are tipped with white. They nest in isolated pairs and two broods are produced a year. There is a large number of domestic pigeons, all descended from a wild form generally believed to be the blue rock-pigeon, but there is now some reason to doubt this. Pigeon breeding has been engaged in throughout Europe and Eastern countries for centuries. It is a favorite pastime in the United States. A great range of variation has been produced by breeding. Some of the more conspicuous varieties are: the fan-tail, with large spreading tail; the pouter, with inflated breast; the tumbler, carrier, trumpeter, barb, and jacobin. Mr. Darwin made use of pigeons in observing the changes produced in animals under domestication, through the influence of artificial selection. The breed called carrier is not the one used for carrying messages, but the homing pigeon is employed for that purpose. There is no real distinction between doves and pigeons.

PASSENGER PIGEON.

Pig'ments, the color materials of painting. It is necessary to distinguish these from dyeing colors. Pigments are insoluble, and, mixed in oil or water or other liquid, are used for painting. Dye-stuffs are held in solution as tinctorial substances. A pigment must have covering power, that is, it must cover and conceal with an opaque covering the surface on which it is spread. When dry, it must have durability; must resist the air. It should also dry quickly. Pigments for artistic work need to be prepared with more care, and of better material, if possible, than for mechanical purposes. A house can be repainted, but a madonna cannot be. Artists' pigments are ground to a finer powder than ordinary paints.

Pike, a ravenous fresh-water fish, with long slender body, broad snout and large mouth. There are five species of the pike family. One inhabits the fresh waters of both continents; the other four are all American. The muskallunge, attaining a length of eight feet, is the finest and largest of the pikes. It is found in the Great Lake region, and, occasionally, in the Ohio valley. The smaller varieties are commonly called pickerel in the United States. They all rank high as food fishes.

Pike's Peak, a peak of the Rocky mountains, 65 miles south of Denver, in Colorado, discovered by Captain (afterward General) Z. M. Pike, in 1806, 14,134 feet high. A railway from Manitou to the top, nine miles in length, was constructed in 1891.

Pi'late, Pon'tius, the Roman procurator of Judæa, who, after his most solemn assertions of the innocence of Christ, yielded to the demands of his accusers and gave him up to be crucified. There are quite a number of traditions as to what was the end of Pilate: that he committed suicide; that he was beheaded by Nero; that he embraced Christianity, and in the Ethiopic church he is celebrated as a saint. One tells how his body was thrown into the Tiber, making an overflow; another that the body was carried to Mount Pilatus, and there sunk securely in the deep pool on its top. But here again it made storms arise, and every year the devil, on Good Friday, lifts him out of the pool and places him on the judgment seat, where he washes his hands anew. In the Greek church, Pilate's wife has been canonized as a saint. His era is the first half of the 1st century.

Pile-driver, a machine for driving piles. The ordinary form consists of a heavy iron weight which can be raised vertically from ten to forty feet between upright guides and then be released to fall on the pile beneath. The common weight of the ram is from 1,000 to 2,000 pounds, but weights of 4,000 pounds and over are occasionally used. It is usually lifted by a wire rope, which is wound up on a drum revolved by a small steam engine, the ram being released when the desired height is reached. In the Vulcan-Nasmyth steam pile-driver, a hammer is attached directly to the rod of a piston which works in a vertical steam cylinder. The admission of the steam to the cylinder causes reciprocating hammering, the number and character of the blows

being regulated by an adjustable valve-gear. Another form of pile-driver is the gunpowder pile. In this the explosive force of gunpowder confined in a suitable mortar is used to drive the pile.

Pileus (*pī'le-ŭs*), the spreading cap-like portion of a mushroom or toadstool. See BASIDIOMYCETES.

Pil'grim Fathers, the founders of the first English colony settling in Massachusetts. This colony belonged to a sect of separatists originating in Yorkshire, England, who had, previous to their sailing for the New World, spent some time as exiles for religion's sake in Holland. The company, numbering 100 men, women, and children, set sail from Plymouth, England, Sept. 6, 1620, bound for the banks of the Hudson. But after a long and stormy voyage, they were driven on the bleak and desolate shores of Cape Cod. They landed Dec. 21, 1620, at a place to which they gave the name of Plymouth. A monument to their memory has been erected there. Before landing they drew up and signed a compact of government, which is regarded as the first written constitution we have an historical account of.

Pil'lory, an instrument for the public exposure and punishment of criminals. It consisted of a post and frame fixed on a platform. In the frame, which is attached to the post after the manner of a sign-board, are three holes through which the hands and head of the criminal are thrust, and out of which he cannot draw them. Thus standing behind the frame he faces the gazing crowd. The exposure was a chief part of the punishment. It was at one time customary to shave the head wholly or partially.

In the laws of Edmund I. it was required to so construct the pillory as not to put the body "into peril." In the earliest pillory punishments, they seem to have been confined to offenses not amounting to felony, called misdemeanors, such as using deceitful measures and weights, libel, seditious writings, etc. Later on, common scolds, brawlers, and others were punished in this way. In the 17th and 18th centuries, it came to be used for the punishment of political offenders. It was abolished altogether in Britain in 1837.

Pil'low, Gid'eon John'son, an American soldier, was born in Williamson county, Tenn., June 8, 1806. He graduated at the University of Nashville in 1827, and not long after was admitted to the bar. He served as a delegate to the Democratic convention which nominated James K. Polk to the presidency. During the Mexican war he was appointed a brigadier-general of volunteers. He commanded the right wing at the battle of Cerro Gordo, where he was wounded. Being promoted for gallantry, he took part in the battles of Molino del Rey and Chapultepec, where he was again and more severely wounded. He practiced law in his own state until the beginning of the Civil war, to avert which he had proposed various compromises. But having entered the Confederate service in 1861, he was rapidly advanced to the command of a brigade, and he took part in the battles of Belmont and Fort Donnelson. He was second in command when the latter was taken by the Federal troops, but made his escape. He afterward served under General Beauregard in the southwest. He died in Lee county, Ark., Oct. 8, 1878.

Pi'lot, a person deputed to take charge of the course of a ship through a particular sea reach, or dangerous channel, or out of, or into port. He "stands at the wheel" we say. He must know how to manipulate the rudder and must be familiar with the channel. A steamboat neglecting to have a duly licensed pilot for a given port or reach would forfeit its insurance in case of an accident.

Pinck'ney, Charles Cotes'worth, an American statesman, was born at Charleston, S. C., Feb. 25, 1746. He took part in the earliest movements of the revolution of 1776. In the war which was then brought on, he did noble and conspicuous service. He was Washington's aid-de-camp at Brandywine and Germantown. He saw much active service until 1780, when he was taken prisoner at the surrender of Charleston. A member of the convention that framed the constitution of the United States, he introduced the clause forbidding religious tests of qualification for office. In 1796, he was sent as minister to France, but the Directory refused to receive him, and he had to quit the country. War between France and the United States was at the time threatening. The French intimated to Pinckney and his associates that a gift of money from the United States would avert war. Then Pinckney burst out in the famous utterance: "War be it then; millions for defense, but not a cent for tribute." He was thrice an unsuccessful candidate for the presidency. He died at Charleston, S. C., Aug. 16, 1825.

Pin'dar, the chief lyric poet of Greece, was born about 522 B. C. near Thebes, and died at Argos 443 B. C. He began his career as a writer of choral odes at the early age of twenty years, and soon reaching the highest rank of his profession, composed odes for persons in all parts of the world. Wherever he went he was honored and loved for his own sake as well as for his art. States vied with each other in doing him honor. Though a frequenter of princely houses and kings' palaces, he never lost his manly independence. In his poems he gives advice and reproof as well as praise to his patrons. He warns the great Hiero of Syracuse to avoid flatterers, and cautions one ruler against severity. Two conquerors of Thebes, Pausanias, the Spartan, during the Peloponnesian war, and later Alexander the Great, left no other dwelling

in Thebes standing than the house in which Pindar had lived. Of most of his poems we have fragments only. The *Triumphal Odes*, celebrating triumphs in the Olympian, Pythian, Nemean, and Isthmian games, are entire. A victory won either in the chariot race, for prowess in wrestling, or for skill in music, was held to confer honor not only on the winner and his family, but also on his city, and received a "solemn celebration." Pindar treats the victory not as a mere incident, but as connected with the victor's whole life and history. He loves to dwell on the *moral* side of it not merely on the bodily prowess, but on the temperance, love to parents, or piety, which secured the favor of the gods who granted success. Of myths relating things unworthy of the gods, he says: "I cannot think this way of the divine beings." The groundwork of his poetry consists in the legends which form the Greek religious literature.

Pine, species of the genus *Pinus*, the largest genus of the Conifers, and distributed throughout north temperate regions. They are exceedingly important forest trees, and are developed in a most magnificent way in the western mountain regions. The commonest species in the eastern United States are *P. Strobus*, the white pine; *P. resinosa*, the red pine; and *P. palustris*, the long-leaved or Georgia pine. In the western mountain regions *P. ponderosa*, the great yellow pine, is one of the most important lumber trees. *P. edulis*, the pifion or nut pine, occurs in southern Colorado and southward. One of the most important pines in cultivation is the Scotch pine, *P. silvestris*, the common pine of northern Europe. The Austrian pine, *P. Austriaca* (*P. Laricio*), is a fast growing and massive tree, and common in cultivation.

Pine and Pine Lum'bering in the United States. The pine is a tree belonging to the gymnospermous trees, of the family of *Pinaclæ* and the order *Coniferæ*. It has narrow, angular two or three-edged leaves in bunches of two to five, inclosed in a sheath of membranous scales. One western species has a single rounded leaf in this sheath. There are upward of twenty varieties of pine in the United States, of which fourteen varieties are without much commercial value. Of the remaining the white pine is of greatest value, being straight-grained, easily worked, free from pitch, and, where properly cared for, exceedingly durable. It originally spread in one great forest from Maine through all the northern and upper-lake states; reaching, however, its greatest perfection in Michigan, Wisconsin, and Minnesota. These forests were composed of trees from 75 to 150 feet in height, and from 10 to 11 feet in girth. The red, Canadian, or Norway pine, comes next in value, seldom reaching the dimensions of the best white pines, but reaching, nevertheless, respectable proportions. Its wood is heavy, resinous, and difficult to work. The yellow pine is the most important in the southern states, and is sometimes known as the Georgia pine. Its wood is a dark yellow or orange color. It is hard, heavy, and tough. The long-leaved variety is much sought after for shipbuilding. The Oregon pine or Douglas fir, of the northern Pacific coast, is commercially of great importance, sometimes reaching a height of three hundred feet. The cut of white pines has been so enormous and relentless since the settlement of the country that it is estimated, if the present average of 7,000,000,000 feet of white-pine timber be cut every year and 2,465,368,600 shingles be annually made, the supply will be exhausted in a decade of years. The lumbering interests are drawing more heavily each year upon the forests of the west and south, the improvements in machinery enabling men to use woods which it was impossible to work by hand. The redwood of California, the Douglas fir of Oregon, and the yellow pine of the southwest, are being brought into the market in increasing bulk each year. Thus alone can what remains of our white pine forests be saved from rapid and total extinction.

Pine Bluff, county seat of Jefferson county, Ark., is built on a high bluff on the south bank of the Arkansas river, about 120 miles from its mouth. It lies 38 miles southeast of Little Rock city. It contains iron works, manufactures cotton-seed oil, flour, bricks, and lumber, and ships large quantities of cotton. Population 11,496.

Pine'apple, the fruit of *Ananas sativa*, a member of the *Bromelia* family. It is native to tropical America and has become naturalized in the tropical regions of Asia and Africa. The chief regions of "pine growing," as it is called, which supply the markets of the United States, are southern Florida and the various West Indian islands, the Isle of Pines being named from this industry. The so-called fruit consists of a fleshy cone-like flower cluster which includes the axis and bracts and flowers of a whole inflorescence. Numerous cultivated forms have been developed.

Pink, the name of a species of the genus *Dianthus*, and extended to the members of the pink family. The common pinks of old gardens are supposed to have descended from *D. plumarius*, a native of eastern Europe. The "sweet William" or "bunch pink" is *D. barbatus*, abundant in all country gardens and a native of Europe. The "carnation" or "clove pink" is *D. caryophyllus*, which occurs in a great variety of colors, either pure or variegated, and is grown mostly indoors. Some of the wild flowers which belong to this family are also called pinks, as for example, the "fire pink" (*Silene Virginiana*), which occurs in woods in early spring, and is conspicuous on account of its crimson red petals.

Pins. These simple articles, almost a symbol for a thing of the smallest value, are not only useful, but a prime necessity, yet they did not come into use without the help of art and inventive genius. The earliest kind of pins were probably thorns, or small bones of fish or other animals. Later on, there were pins made of brass, copper, and iron. These were of various forms, and often with gold and ornamental heads. Modern solid-headed pins are made on a machine that was patented by an American named Wright, in 1824. The process is as follows: First, wire of suitable sizes is manufactured, mostly of brass, but iron and steel are also used. When reeled, the wire is ready for use. A pair of pinchers, worked by a machine, draws from a reel of wire a length sufficient to make a pin; its head, which is at the same time made, is straightened by passing through studs. The pin length is seized by jaws from which a portion of the wire, of which the head is to be made, projects and is exposed to blows from a die hammer. The pin is then pushed forward twice, at each time receiving a blow from the die hammer. The wire is then cut to the length of the pin. The headed blanks drop into a slot formed by two inclined and beveled-edged bars. The opening between the bars is just large enough to prevent the heads of the pins from falling through, so that the blanks become sustained in a row along the slot. They are then caught between two parts of the machine, which causes them to rotate, and are thus passed in front of the cylinder which acts like a file and points the pins. As many as 160 a minute can be turned out by a single machine. The pins are cleaned of grease and other matter by boiling them in weak beer. They are next coated in tin, and are then brightened by shaking them in a bag or barrel with bran or sawdust. They are papered by machinery, which is as ingenious as the way by which they are made.

Pipe'fish, a long slender fish with a straight tubular snout, like a pipestem. It is common on the Atlantic coast from Newfoundland south. The male has a brood pouch under the tail, in which the eggs are developed and the young protected for some time after they are hatched. Several other species are found in different seas.

Piq'ua, O., a city of Miami county, on the Miami river and the Miami and Erie canal, in a rich agricultural section, 27 miles north of Dayton, and 72 miles west of Columbus. It is served by the Pittsburg, Cincinnati, and St. Louis, and the Cincinnati and Michigan railroads. It has good water-power from the Miami. Its industries include large linseed-oil works, strawboard, hosiery and woolen mills, furniture, carriage, and stove works, tin-plate and bent-wood works, etc. It has some good schools, and a number of churches, banks, and a public library. Population 12,172.

Pi'racy is robbery on the high seas, and although considered a crime at the present time by all nations, formerly the sea rover was as much a pirate as a trader. Thus the Phœnicians combined piracy with lawful seafaring enterprise. In the days of Homer, piracy was considered a respectable, even a dignified, calling, and the Greeks had a natural genius for it. Cilicia was long the headquarters for Mediterranean piracy, until in 67 B. C. Pompey made his memorable expedition against the pirates with great naval and military forces. The Norse vikings were the terror of western coasts and waters from the 8th to the 11th centuries. The Hanseatic league was formed for mutual defense against the Baltic and other pirates. Later, the Moslem rovers scourged the Mediterranean commingling naval war on a large scale with peddling, thieving, and stealing slaves. Algiers was a stronghold of pirates till well into the 19th century, and in the 17th century the English channel swarmed with corsairs, Algerine pirates. In 1635, they actually entered Cork harbor, and carried off a boat with eight fishermen, to be sold as slaves in Algiers. The buccaneers preyed mainly on the Spanish commerce with the Spanish-American colonies. Captain Kidd, who was sent out against pirates in 1696 by a private company in London, was found to be playing the game of pirate himself, was arrested and tried for piracy and murder, found guilty and hanged May 23, 1701. The original of Scott's "Pirate" was John Gow, who, though bold and successful under the guise of friendship, was proved to be a great villain, and with nine of his men was executed. So late as 1864 five men were hanged in London for murder and piracy. The African slave trade was not considered piracy by the law of nations, though the United States and Great Britain declared it to be so by statute, and after 1841 Austria, Prussia, and Russia made the same declaration. The home of professional piracy is now confined to the Malay peninsula.

Piræus (*pī-rē'us*), the harbor of Athens, Greece; Athens being about five miles from the sea. As far back as the time of Pericles, long walls joined the port with Athens. These were built for protection, so that between them travel to and from the port and the city would be undisturbed. A few traces of the wall remain. The fortification being destroyed by Sulla 86 B. C., the town fell into decay. Since 1834, the modern town has grown up, for more than half the export trade of Greece passes through the port of Piræus. It has a large trade. Population 42,169.

Pisa (*pē'zȧ*), one of the oldest cities of Italy, and once the rival of Venice and Genoa. It still has standing walls and a citadel, and is situated on the river Arno, 50 miles west of Florence and 13 miles northeast of Leghorn, to which place its once prosperous

commerce has been almost wholly transferred. It is still a city of fine buildings, foremost among which is the cathedral, built in the 11th century, with a noble dome, fine paintings by Cimabue, Andrea del Sarto, and others, and beautiful marble altars. In shape it is a Latin cross, 311 feet long, by 252 wide; the nave is 109 feet high. Outside it has a magnificent façade of four rows of pilasters and arches, and fine bronze doors by Giovanni de Bologna and others. Near by stands the "Leaning Tower of Pisa," which is a splendid specimen of the southern Romanesque architecture, but is peculiar in that it deviates about 14 feet from the perpendicular. This is not due to original design. The tower seems to have begun to heel over to one side when the third story was completed; the architects deliberately accepted the conditions and adhered to the inclining position, but diminished the slope of the upper stories so as to keep the center of gravity well within the walls. The tower is 180 feet in height, consists of eight stories, divided by rows of columns, the last, which contains the bells, being smaller in diameter than the others. The tower was built in 1174 and succeeding years, but the eighth story was not completed until the middle of the 14th century. The marble baptistry or church of St. John (1152–1278), opposite the cathedral, is circular, and supports a dome crowned with a cupola. The interior, noted for its wonderful echo, contains the elaborate pulpit of Niccola Pisana. Pisa contains numerous other churches, some of great age, and many fine palaces, a university, which dates from 1338, with fine library of 150,000 volumes, natural history museum, botanical garden, 1,087 students and 56 lecturers. Many distinguished Italians were born here. Among them Galileo, Giovanni, Pisano, Leonardo the mathematician, and two popes, Eugenius III. and Nicholas V.

Ancient Pisa was an Etruscan city, which became subject to Rome in the 2d century B. C. Early in the 11th century, Pisa had developed into a powerful republic, possessing a formidable fleet and much territory along the Tyrrhenian sea. Throughout the 11th century, Pisa was at the height of its prosperity, and the splendid monuments of art still adorning it belong to this period. In the succeeding conflicts between the Guelphs and the Ghibellines, Pisa lost and gained until in 1284 the Pisan fleet was crushed at Meloria by the Guelphs, headed by Florence and Genoa. From this time, Pisa, having to surrender much territory, declined steadily, until in the middle of the 16th century it had less than 8,600 inhabitants. Population of modern Pisa 66,567. The industries are now confined to silks, cottons, ribbons, and the working of coral and alabaster.

Pisidia (*pi-sid'i-ă*), in ancient geography, was a country in Asia Minor, north of Pamphylia, which separated it from the Mediterranean, and south of Phrygia. It was a rugged and mountainous district comprising some of the loftiest portions of the great range of the Taurus mountains. The rivers are the Cestrus and Eurymedon, and it has in its northern part a fresh-water lake, about 30 miles long. In early times it was occupied by wild, lawless races of mountaineers, who were never entirely subjugated by the various powers ruling Asia Minor at different times. The first mention of Pisidians in history occurs in the *Anabasis* of Xenophon. Later, they resisted the march of Alexander the Great through their country. In Strabo's time they had passed quietly under the Roman power. Pisidia once contained considerable towns, the ruins of which have been brought to light recently by Arundell, Hamilton, and Daniell. The most remarkable ruins are those of Termessus, Cremna, Sagalussus, Sedge, a large and wealthy city in Strabo's time, and Antioch, which Paul visited.

Pisistratus (*pi-sis'tra-tus*), a tyrant of Athens, was born 605 B. C. He was at first in sympathy with Solon, the great Athenian lawgiver, but afterward he came out as leader of one of the parties into which Attica was divided. The one he joined was composed chiefly of the laboring population, anxious for political privileges. He came into the market place with self-inflicted wounds, calling upon the people to protect him from his enemies. A motion to give him fifty men for a body-guard was carried against the strong opposition of Solon. This guard he gradually increased until he became strong enough to take possession of the Acropolis. The leader of the opposing party fled from the city, but returned five or six years afterward and drove Pisistratus into exile. But supported by Thebes and Argos he was able to retake Athens in a short time. He held power at Athens for sixteen years after this, dying in 527 B. C. In the main he ruled Athens well, enforced the laws of Solon, secured provision for old and disabled soldiers, emptied the city of its poorest citizens by supplying them with seed and cattle, and encouraged literature more than any other Athenian had ever done. To him and to the poets and scholars whom he gathered about him the world owes the first complete edition of Homer.

Pis'til (in plants), a term of somewhat indefinite application, inasmuch as it may consist of one carpel or of several carpels organized together. In the former case the pistil is spoken of as simple, in the latter case as compound. In other words, any organization of carpels which appears as a single organ with one ovary is a pistil. See FLOWER.

PISTIL. (*a*) style; (*b*) stigma; ovary hidden in flower.

Pis'tol. See REVOLVER.

Pit'cairn' Island, a solitary island in the Pacific ocean between Australia and South America, area two square miles. It owes its celebrity to its being the dwelling place of the "Mutineers of the Bounty." The British ship *Bounty* was sent out by the government for the purpose of carrying bread-fruit trees to the West Indies to be transplanted. The ship got to Tahiti a few months too soon for the season for removing the trees; hence the crew became demoralized. A short time after leaving Tahiti, twenty-five of the crew mutinied. The commander, Bligh, with a number of his officers, was set adrift in a launch. He made out to reach the Dutch East Indies. The mutineers at first went back to Tahiti. Six of those who chose to be landed at Tahiti were condemned to death, and three were executed in England (1792). In 1790, nine of these mutineers, with six Tahitian men and a dozen women, on the *Bounty*, sailed to and settled on Pitcairn island. Four years later, the Tahitian men murdered all the Englishmen, save one Alexander Smith, who changed his name to John Adams. Another report is, that the Englishmen and Tahitians murdered each other from time to time. It is certain, "that at the end of ten years John Adams was left alone with eight or nine women and several children, and that from them the present inhabitants (now 126 in number) are descended, the mutineers taking possession of the island in 1790. Adams set about the Christian education of the company. Nothing was known of them till 1808, when the American ship *Topaz*, Captain Folger, discovered them. Not until 1814 did a British vessel touch at the island. In 1831, a British vessel at their own request transferred them to Tahiti. They then numbered 87. They remained there not quite a year, and returned to Pitcairn. In 1839, it was annexed to Britain. In 1856, nearly 200 were transferred to Norfolk island, but a number of them returned. The late Queen Victoria at one time sent them a cabinet organ. The people are virtuous and contented, and choose their own pastor and magistrate.

Pitch. In mechanics, pitch is used to denote the distance between two successive threads on a screw measured along the axis of the screw. In acoustics, pitch is used to denote one of the three distinguishing features of any musical tone. The pitch of a note depends upon the number of vibrations per second which produce this note; and the numerical value of the pitch is the number of vibrations per second, or the *frequency* of the note. See ACOUSTICS.

Pitch, a black resinous substance, is obtained from the tar of coal or of wood by the application of heat at low temperatures, the heat driving out the volatile naphtha or spirit. In the production of pitch, the fire must be withdrawn before the heat of the distilling vessel reaches the point at which coke or carbon will be produced. Pitch is also obtained from natural petroleum, bone tar, and stearine residues. The two last are valued by varnish and turpentine makers. Wood-tar pitch is much used to protect timber from insects and the weather; coal-tar pitch is used in the manufacture of black varnishes for coating iron, and for making lampblack, etc. In Persia, it is prepared from goat and sheep dung. Burgundy pitch, produced in Finland, is a drug much used as a medicine.

Pit'cher Plants, those whose leaves form tubes or urns of various shapes, which contain water, and to which insects are attracted and drowned. The common pitcher plants of the temperate regions are a species of *Sarracenia*, which grow in swampy areas. In the tropics, striking illustrations of pitcher plants are found among the various species of *Nepenthes* and their allies, in which urns of various shapes are developed swinging at the ends of tendrils. See CARNIVOROUS PLANTS.

PITCHER PLANT.

Pith, a term which has both a general and a special application. In the former case, it applies to any loose, spongy tissue in plants. Strictly, however, it means the spongy tissue within the vascular cylinder of gymnosperms and dicotyledons. The tissue is parenchyma (which see), and it is apt to die very early, so that the pith of ordinary experience is a dead and empty mass of cells. The pith of ordinary commercial use is obtained from the elder.

Pit'man, Sir **Isaac,** a British educator, and the father of modern shorthand writing, was born at Trowbridge, Wiltshire county, England, Jan. 4, 1813. He was educated at the Normal college near his home, and became himself the master of a school at Barton-on-Humber in 1832. He published his first studies of the art which was to make him famous, in 1837, in a volume entitled, *Stenographic Shorthand.* A few years later he put forth a second volume, which he called *Phonography, or Writing by Sound.* Such was the general acceptance his system found, that little remains of earlier attempts. In 1843, he founded the Phonetic society, and soon after began the publication of the weekly *Phonetic Journal.* He issued many text-books upon phonography, and his system was introduced into the United States in 1847. He was knighted in 1894, and died Jan. 22, 1897. His brother, Ben Pitman, settled at Cincinnati about 1850, and made that city the headquarters for the publication of works similar to those printed by Isaac in the Old World. His system differs slightly from that of his brother, but essentially they are one.

Pitt, William, earl of Chatham, sometimes styled "Pitt the Elder," one of the greatest English orators and statesmen of the 18th century, was born at Westminster, Nov. 15, 1708. He was educated at Eton and Oxford, and entered parliament in 1735, where he took sides against the king, and led the young Whigs, known as patriots, in opposition to Walpole, then at the head of affairs. Though deprived of his commission, his influence increased rapidly both in and out of the house of commons. Walpole was driven from power in 1742, and though the king hated Pitt, he found it necessary to permit his return to the government service. Some wealthy admirers of Pitt's oratory and patriotism left him large sums of money, and, on the dismissal of Fox, Pitt became secretary of state. While Pitt was in power, success returned to the British arms. French armies were beaten everywhere by Britain and her allies —in India, in Africa, in Canada, on the Rhine—and the few ships left her were driven from almost every sea. But Pitt, the prime mover of all these brilliant victories, found himself compelled to resign on the accession of George III., when the British government adopted a vacillating policy. But he did not cease to take an interest in public affairs. He spoke strongly against the arbitrary and harsh policy of the government toward the American colonies, and warmly urged an amicable settlement of the difficulties. But when, America having entered into treaty with France, it was proposed by the duke of Richmond to remove the ministers, and make peace on any terms, ill though he was, Chatham came down to the house of lords. In a powerful address, he protested against the implied prostration of Britain before the throne of the Bourbons, and declared that war, with whatever issue, would be preferable to the proposed terms of peace. This address secured a majority against the motion, and the war was continued. But it was the orator's last effort, for his physical powers suddenly failed, he fell back into the arms of his friends, and was carried from the house by his son William, who in less than five years was himself prime minister. Chatham died in Kent, May 11, 1778. He was buried in Westminster Abbey, where a statue was erected to his memory. See his *Life*, by F. Thackeray.

WILLIAM PITT.

Pitt, William, the second son of the great earl of Chatham, was born May 28, 1759, in Kent, England, while his father was still in the house of commons, and the man most honored in England. Owing to ill-health he was educated at home, his father carefully superintending his studies, and training him in those lines which would best fit him for a brilliant career in parliament. To this was due that wonderful command of choice and accurate English which Pitt possessed above all the orators of his time. He entered parliament, Jan. 23, 1781, and his first speech made a great impression. Burke said: "He is not a chip of the old block, but the old block itself." A member of the opposition said to Fox: "Pitt will be one of the first men in parliament." To which Fox replied: "He is already the first." Although but twenty-three years of age, and poor, he refused the office of vice-treasurer of Ireland, saying he would accept nothing but a seat in the cabinet, and although this speech caused wide-eyed astonishment at the time, three months later he was in the cabinet as chancellor of the exchequer. A year later, the king, George III., urged him to act as premier and choose his associates, but with rare judgment and self-restraint, Pitt declined the dazzling offer. However, on the speedy fall of the coalition ministry then formed, with Fox and North as joint secretaries of state, the king arbitrarily appointed Pitt chancellor of the exchequer and first lord of the treasury. The best judges in the political world then considered his position hopeless, and foretold for him a briefer ministry than even the last three had been. He was opposed by North, Sheridan, and Burke, who united against him, but his dauntless courage, skill, and firmness won him the battle, and on March 25, 1784, parliament was dissolved and Pitt, only twenty-five years of age, was elected minister. He was one of England's most powerful premiers, and held sway for twenty years. He died at Putney, Jan. 23, 1806, and was buried beside his father in Westminster Abbey. See biography, by Lord Stanhope; and *Pitt*, in the "Twelve English Statesmen" series, by Lord Rosebery.

Pitts'burg, the second city of Pennsylvania in regard to population, wealth, and manufactures, is situated at the junction of the Allegheny and Monongahela rivers, which here form the Ohio. It is about eight miles long and five miles wide at its eastern limit, and covers an area of about twenty-seven and three-fifths square miles. Fort Pitt, the first building erected in the present city of Pittsburg, was begun by the French as Fort Duquesne, in 1753, and was abandoned and destroyed by them during the French and Indian war, and rebuilt, in 1758, by the English under General Forbes. The city was incorporated in 1836, and in 1900 the population was 321,616. Pittsburg is the center of the greatest natural-gas field and petroleum-producing territory in the United States. It

is also surrounded by the most extensive bituminous coal-field yet developed, and is extensively engaged in the manufacture of coke. The making of iron and steel, particularly armor plate, structural steel, and steel rails, is the leading industry. In the manufacture of plate glass, Pittsburg leads the world. Other leading industries are the manufacture of locomotives and steel cars, brass goods, brick, salt, chemicals, paper, and electrical supplies. The facilities for transportation are particularly fine; the Allegheny and Monongahela rivers are each navigable for over one hundred miles, and the Ohio connects the city with the Mississippi and the gulf of Mexico. The Pennsylvania, the Baltimore and Ohio, and the Vanderbilt systems of railways center in Pittsburg. In 1900, the river and railway tonnage exceeded that of any other city in the world. There are two hundred churches, a number of private schools and academies, and eighty-four public schools including three high schools. The public schools enroll 40,197 pupils, and employ 990 teachers. Pittsburg has many fine buildings, the principal ones being the Courthouse, the United States Government building, the Carnegie institute, the union depot, the Lake Erie depot, the Schenley hotel, and the Exposition building. The city is connected with Allegheny, and other suburbs, by seventeen bridges, and has over four hundred miles of streets and boulevards. There are six parks, Schenley park being one of the largest in the United States, and Highland one of the most beautiful.

Pitts'burg, Kans., a city and railroad center in Crawford county, southeastern Kansas, 50 miles east of Independence, and 10 miles south of Girard, the county seat. It is on the Atchison, Topeka, and Santa Fé, the Kansas City, Pittsburg, and Gulf, the Missouri Pacific, and the St. Louis and San Francisco railroads. It has in the vicinity rich coal lands and mineral deposits, coal-mines, zinc-works, etc. There are good schools, churches, banks, and the civic facilities of a growing town. Population 10,112.

Pitts'field, a city of Massachusetts, 150 miles by rail from Boston. Beautifully situated on a plateau, where six lakes around the city give rise to the Housatonic river, it contains a marble courthouse, a handsome athenæum, a women's seminary, and has a fine park near its western border. Among the manufactures are cotton and woolen goods, silk, boots and shoes, etc. Population 21,766.

Pitt'ston, Pa., an old and now growing city, in Luzerne county, on the Susquehanna river, and in the center of the rich anthracite coal region of northeastern Pennsylvania, about midway between Scranton and Wilkesbarre. Its manufactories, which have the advantage of abundant and cheap fuel, include machine shops, planing, knitting, flour, and paper-mills; stove and steel-range works; terra-cotta works, ladies' underwear factory, dye-works, and pressed-brick works. West Pittston, across the river and connected with it, is the chief residential part of the city. Pittston was named after the English statesman, William Pitt, and was settled about 1770. Population 12,556.

Pi'us, the name of nine popes:—

Pius V., originally named Michele Ghislieri, was born of poor parents, at the village of Bosco, near Milan, in the year 1504, and at the age of fourteen entered the Dominican order. His merits were recognized by Pope Paul IV., who appointed him bishop of Sutri and Nepi, in 1556, and cardinal in the following year. Being chosen pope, in 1566, he labored to restore discipline and morality at Rome, prohibited bullfights and other objectionable amusements, and regulated the taverns of the city. He also zealously maintained the inquisition, and sought to suppress heresy with a strong hand wherever it was found. But the most important event of his pontificate was the expedition which he organized, in connection with Spain and Venice, against the Turks, which resulted in the great naval victory of Lepanto, Oct. 7, 1571. He died in the following year, and was canonized by Clement XI., in 1712.

Pius VI., originally named Giovanni Angelo Braschi, was born at Cesena, Italy, Dec. 27, 1717, and on the death of Clement XIII., in the year 1775, he was chosen to the pontificate. His administration was enlightened and judicious, and to him Rome owed many substantial improvements. Soon after his accession, however, he was involved in serious conflict with the Emperor Joseph of Austria and Leopold of Tuscany, by whom he was deprived of a considerable portion of his supremacy. Soon after came the French revolution and the confiscation of all church property in France. The pope launched his thunders, but they were not heeded, and soon the storm burst upon his own head. The murder of the French political agent, Basseville, in a street scuffle at Rome, gave the French directory an excuse for attacking him. In 1797, peace was secured by the treaty of Tolentino; but new causes of contention soon arose, and, in 1798, the French marched upon Rome and took possession of the castle of St. Angelo. Pius was called upon to renounce his temporal sovereignty, and on his refusal to do so was imprisoned and carried to Florence. On the threatened advance of the Austro-Russian army, in the following year, he was transferred to Grenoble, and thence to Valence, on the Rhône, where he died, Aug. 29, 1799.

Pius VII., originally Gregorio Luigi Barnaba, was born at Cesena, Italy, Aug. 14, 1742, and became pope in the year 1800. Rome, which had been occupied by the

French for the past two years, was now restored to the papal authority, and the next year the French troops were withdrawn from the city. In 1804, Napoleon compelled Pius to come to Paris to consecrate him as emperor. He was well received, but in less than six months after his return to Rome, French troops seized Ancona and, finally, in 1809, General Miollis entered Rome and took possession of the castle of St. Angelo. The usurpation was consummated in the following year by a decree annexing Rome and all the papal territory to the French empire. The pope was then removed to Grenoble, thence to Savona, and finally to Fontainebleau, and at the latter place was compelled to sign a concordat recognizing the annexation of the Roman states to the empire. After the downfall of Napoleon, the congress of Vienna restored his territories to him, and May 24, 1814, he re-entered Rome, the remainder of his reign being devoted to wise measures of internal administration. Throughout his life, Pius was a model of gentleness, benevolence, and Christian charity. He died Aug. 20, 1823.

Pius IX., originally Giovanni Maria Mastai Ferretti, was born at Sinigaglia, Italy, May 13, 1792. In 1840, he became a cardinal, and on the death of Gregory XVI., in 1846, was elected to succeed him. He was avowedly the leader of the reform party, and one of his first acts was to grant an amnesty to all prisoners and exiles for political offenses. In March, 1848, he published his scheme for the government of the papal states by means of two chambers, one nominated by the pope and one chosen by the people. But the revolutionary fever of 1848 spread too fast for a reforming pope, and on Nov. 15, his minister, Count Rossi, was murdered in broad daylight. A few days later, the pope himself escaped to Gaeta, a Neapolitan seaport near the Roman frontier, from which place he issued a remonstrance to the various sovereigns of Europe. In April, 1849, a French expedition was sent to Civita Vecchia, and in July General Oudinot took possession of Rome, Pius himself returning and resuming his authority in the following year. After this, his policy was the reverse of what it had been, and he continued to the end of his life an unyielding conservative. In his ecclesiastical policy he was active, and uncompromising is his ultramontanism. By a bull, issued in 1854, he decreed the Immaculate Conception of the Virgin Mary as a doctrine of the church. But the most important event of his pontificate was the Vatican Council, at which bishops from all parts of the world assembled in December, 1869, and continued in session until the month of July, 1870. This council first formally proclaimed the doctrine of the papal infallibility, whenever the head of the church issues a decree on a subject of faith and morals to the universal church. For several years previous to this, the pope's temporal authority had been maintained only by French bayonets, and when the garrison at Rome was withdrawn, on the outbreak of the war with Germany, in 1870, the soldiers of Victor Emmanuel entered Rome, and for the remainder of his days the pope lived a voluntary prisoner within the Vatican, only his spiritual power remaining to him. He had the mortification to see Rome the capital of a united Italy, and Victor Emmanuel enthroned in the Quirinal with the affection of all his subjects. He died at Rome, Feb. 7, 1878, and was succeeded in the popedom by Leo XIII. (born 1810, created pope 1878).

Pizar'ro, Francis'co, the conqueror of Peru, was the illegitimate son of a Spanish colonel of infantry, and was born about the year 1470. He never learned to read and write, but entered the army at an early age and served under the "Great Captain," Gonsolvo di Cordova, in Italy. He was also one of Balboa's party that discovered the Pacific ocean, and soon after this became a resident of the isthmus of Panama, on the Pacific coast. From this point, in connection with another old soldier, named Diego de Almagro, he started on an expedition for the conquest of Peru, in the year 1526. But not being strong enough to land and form a settlement, Almagro was sent back to Panama for re-enforcements, while Pizarro and part of the force remained on an island named Gallo. But the governor of Panama refused to give any further support to the enterprise, and sent two vessels to bring Pizarro and his men back to Panama. The latter refused to return, and, drawing a line on the sand, called upon all the men who wished to remain with him and share in the success of his enterprise to come over to his side. Thirteen men crossed the line, and the others returned to Panama. Soon after this, the governor of Panama was induced to send one vessel to Pizzaro, with which he explored the coast of Peru and collected information concerning the empire of the Incas. He then returned to Panama, and soon afterward proceeded to Spain, where he applied for authority to undertake the conquest of Peru. On July 26, 1529, a commission was given him for his enterprise, with the title of captain-general, while Almagro received the title of marshal. Pizarro sailed from San Lucar on January 19, and from Panama the following year, with three vessels, containing less than 200 men, and about thirty or forty horses. Almagro was to follow with re-enforcements. Landing at Tumbez, the Spaniards commenced the march inland in May, 1532, and in November entered the city of Cajamarca. The Inca Atahualpa, being on his way to Cuzco, the capital of his empire, was treacherously captured and put to death by Pizarro, who first extorted a large sum, equal to several million dollars, for his ransom. Pizarro then marched to Cuzco, and set up the young Inca Manco, as nominal sovereign of the empire,

being careful to retain the real power in his own hands. In 1535, he founded the city of Lima as the capital of his new government. Two or three years later, a fierce quarrel arose between Pizarro and Almagro, the latter claiming that he was the lawful governor of Cuzco, and that he had not received his full share of the honors and riches to which he was entitled. This contest almost assumed the proportions of a civil war, and resulted in Almagro's being captured and beheaded by Pizarro. But Almagro's followers, driven to desperation by the manner in which they were treated by Pizarro, formed a conspiracy against him, and June 26, 1541, he was attacked in his house at Lima while partaking of his midday meal, and assassinated, his body being buried in the cathedral by stealth and at night. Pizarro's name is one of the most prominent in the history of the conquest of the New World. He was able, brave, and resolute, but perfidious and cruel to the last degree. The execution of the Inca Atahualpa is a stain upon his reputation that time will never remove; like the blood on Lady Macbeth's right hand, it is a "damnéd spot" that cannot be washed out.

Plague, a term applied during the middle ages to all fatal epidemics, but now restricted to a contagious fever prevailing at certain times and places epidemically. The general symptoms resemble those of other fevers — shivering, rise of temperature, pain in the head, back, limbs, etc. Bleeding from the lungs, though rare in recent epidemics, was formerly regarded as a characteristic symptom of the "black death" in its most virulent form. About the second or third day the most distinctive features of the disease present themselves, viz., glandular swellings, usually in the neck, armpits, or groins; these generally break and lead to prolonged suppuration. The cause of the epidemic has never been determined. It is certainly very infectious, and the infection may be conveyed by clothes, bedding, etc., as well as by direct contact with the sick. It is also the most destructive of all epidemics. The black death of 1348–50 is believed to have destroyed more than half the population of Europe. The first extensive outbreak of this disease was in the 6th century of our era, and devastated the whole Roman empire. It is supposed to have originated in Lower Egypt; but from this time on frequent epidemics occurred in Europe. The last outbreak in England was in the year 1665, and was called the "Great Plague of London." Nearly 100,000 persons perished in London alone during its ravages. Since the end of the 17th century it has only twice visited western Europe; in 1704–14 it spread from Russia and Hungary as far as Sweden, Denmark, and Bavaria, and in 1720–22, being introduced into Syria from Marseilles, it destroyed almost half the population there, and spread through Provence. The last cases known in Egypt were in 1844, and since that date it has occurred more than once in Arabia, Tripoli, Persia, and Mesopotamia, and in 1878–79 it spread to southeastern Russia.

Plain'field, N. J., an attractive city in Union county on the Central Railroad of New Jersey, 10 miles north of New Brunswick, and 25 miles west of New York city. It has some charming residences and is tastefully laid out. It has a number of good schools and churches, public library, art gallery, the Muhlenberg hospital, and other civic and philanthropic institutions. Its manufactures embrace carpet, oil-cloth, and machine-tools works, together with an establishment for the manufacture of printing-presses. Population 15,369.

Plane'tree, the oriental plane, a native of Greece and the east, was planted by the Greeks and Romans as an ornamental tree, and for centuries the youth of Greece assembled under its shade in the groves of academies to receive lessons in philosophy. It is still planted for shade and ornament in the south of Europe, and there are no finer trees in London than its planetrees. Noble specimens are to be seen in Hyde park and Russell square, and the avenue of the Thames embankment is formed with this tree. In the east the planetree attains a great size. One in the meadow of Buyukdere, on the banks of the Bosphorus, is 140 feet in circumference at the base, and is believed to be 2,000 years old. The North American plane, or buttonwood, is very similar to the oriental plane. It is the largest evergreen tree of the United States, and abounds on the banks of rivers in the middle states.

Plan'ets. If one observes the sky night after night he finds that practically all the stars maintain their relative positions; but there are certain heavenly bodies, besides the sun and moon, which form a striking exception to this general rule. There were five of these bodies known to the ancients who called them "planets" which is merely the Greek word for "wanderers." To these five bodies had been given the names Mercury, Venus, Mars, Jupiter, and Saturn. Copernicus, by placing the sun at the center of the solar system, showed that the Earth also belongs in this same group of bodies. On March 13, 1781, Sir William Herschel discovered what he at first thought was a comet, but which proved, within a year, to be another planet, the one we now call Uranus. On September 23, 1846, an eighth planet, Neptune, was found by Galle at Berlin almost exactly at the point in the heavens where it had been predicted by Leverrier in France, and by Adams in England, a discovery which is justly celebrated as the most brilliant achievement of modern astronomy. Besides these, nearly 500 smaller planets called "asteroids" have been discovered during the 19th century. See ASTEROIDS.

The following table giving the distances and periods of the various planets is taken from Young's *General Astronomy*, p. 295.

NAME.	DISTANCE FROM SUN.	SIDEREAL PERIOD.
Mercury -	0.387	88 days
Venus - -	0.723	224.7 "
Earth - -	1.000	365¼ "
Mars - - -	1.523	687 "
Mean Asteroid -	2.650	3 to 8 years
Jupiter - -	5.202	11.9 years
Saturn - -	9.539	29.5 "
Uranus -	19.183	84.0 "
Neptune -	30.054	164.8 "

It will be observed that the distance from the sun is given in terms of the distance of the earth as a unit. The relative sizes of the planets and the sun are well shown in the accompanying figure:

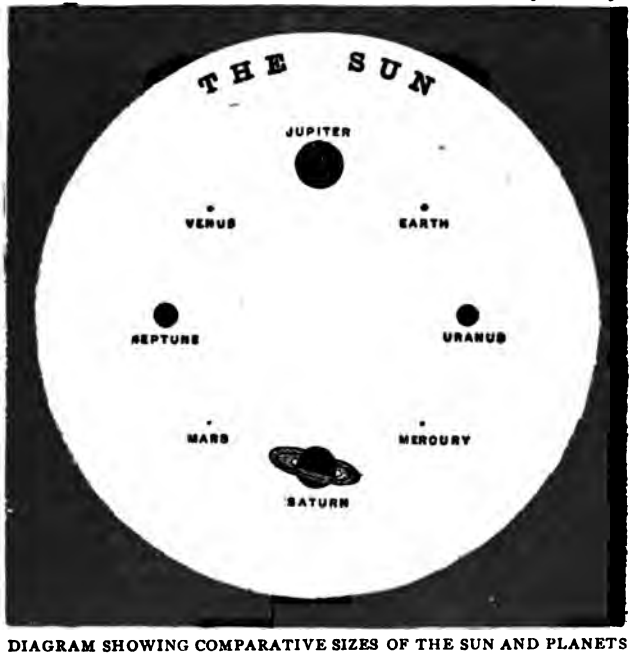

DIAGRAM SHOWING COMPARATIVE SIZES OF THE SUN AND PLANETS

For the laws which describe the motion of the planets about the sun, the reader is referred to the articles *Kepler*, and *Newton*.

Concerning the individual planets it may be noted that—

1. MERCURY, which is nearest the sun, has also the least diameter and the least mass, but the greatest density of all the planets. Its density may be remembered from the fact that it is almost exactly that of the metal mercury, being 12½ times that of water. The diameter of this planet is about 3,000 miles. No satellite has been discovered for Mercury.

2. VENUS has a diameter of 7,700 miles and a density 0.86 that of the Earth, so that in size, surface, gravity, etc., she is not very different from our own planet. No satellite is known.

3. EARTH. See article EARTH.

4. MARS has a diameter of 4,200 miles, and a density which is 0.73 that of the Earth, so that bodies at the surface of Mars weigh only 0.38 what they would at the surface of the Earth.

Two satellites of this planet were discovered by Professor Hall at Washington in August, 1877. These two moons, *Deimos* and *Phobos*, are exceedingly minute, being only 7 and 5 miles, respectively, in diameter. The surface of Mars is covered with interesting markings.

5. ASTEROIDS. See article ASTEROIDS.

6. JUPITER, the largest of all planets, has a diameter of 86,500 miles; and while its density is only one-quarter that of the Earth, its mass is 316 times as great, so that a body on the surface of Jupiter weighs more than twice as much as the same body at the surface of the Earth.

The surface of this planet exhibits some very characteristic markings, especially belts and spots, which lead to the opinion that Jupiter is a body of very high temperature compared with the other planets. He has five satellites, four discovered by Galileo, and one recently (1892) discovered by Barnard at the Lick observatory.

7. SATURN, with its system of rings, is conceded to be one of the most superb objects in the heavens. Although the diameter of the planet is only 73,000 miles, the outer ring is no less than 168,000 miles across. Two rings had been known for a long while, but the third ring was discovered by Bond in 1850. Pierce and Maxwell have proved that these rings are made up of discreet particles, and that the rings, therefore, are neither solid nor liquid. See article MAXWELL. Saturn has eight satellites discovered between the years 1665 and 1848.

8. URANUS, discovered by the elder Herschel, has a diameter of 32,000 miles; but its density is only about one-fifth as great as that of the Earth, so that notwithstanding its enormous bulk, surface gravity there is only 0.90 that of the Earth. It is accompanied by four satellites.

9. NEPTUNE, the most distant member of the family has a diameter of 35,000 miles and a density one-fifth that of the Earth. At an average distance of 2,800 millions of miles from the sun, it is absolutely invisible at the

Earth, except by the aid of a telescope. It has one satellite, discovered almost immediately after the discovery of the planet itself. See Miss Clerke's *History of Astronomy*, and Chambers' *Descriptive and Practical Astronomy.*

Plantag'enet, the name of a family that in 1154, in the person of Henry II., succeeded to the throne of England, on the extinction of the Norman dynasty in the male line, and reigned till 1485, when the battle of Bosworth gave the crown to the house of Tudor. The Plantagenet kings were Henry II., who reigned from 1154 to 1189; Richard I., who reigned from 1189 to 1199; John, from 1199 to 1216; Henry III., from 1216 to 1272; Edward I., from 1272 to 1307; Edward II., from 1307 to 1327; Edward III., from 1327 to 1377; Richard II., from 1377 to 1399; Henry IV., from 1399 to 1413; Henry V., from 1413 to 1422; Henry VI., from 1422 to 1455; Edward IV., from 1455 to 1483; Edward V., who, being a youth of thirteen when his father died in 1483, was placed in the Tower by his uncle, Richard III., and was there supposed to have been murdered by Richard's order; Richard III., who reigned from 1483 to 1485. See articles under these several names, and for the great struggle between the rival branches of the Plantagenets, see ROSES, WARS OF THE.

Plan'tain, species of *Plantago*, a genus containing more than 200 species, which are distributed everywhere, at least twenty plantains being known in North America. They all have a common habit, namely, a a rosette-like cluster of basal leaves from the center of which there rises a stalk bearing the more or less elongated dense spike of inconspicuous flowers. In the common plantain this spike is often said to resemble a rat's tail. By far the most common species is *P. major*, the dooryard plantain, which has received numerous other common names. Perhaps the next commonest form is *P. lanceolata*, known as ribwort, rib grass, and scores of old names.

Plasmo'dium, the naked protoplasmic body of the slime molds. It consists of numerous fused naked cells and has the power of motion, like a huge amœba. See MYXOMYCETES.

Plas'ter of Par'is is a name given to gypsum (*q. v.*) prepared for use in the arts, the name arising from the fact that the most famous beds of gypsum in the world are those of Montmarte, near Paris, and the product is shipped from that city. The plaster itself is merely gypsum, the natural bihydrated calcium sulphate, heated and ground fine. In this condition it constitutes a powder devoid of moisture, which moisture has been driven off by heat. But upon the reapplication of water to the mass it rapidly assumes solid form again. This property renders the material invaluable to the designer who can fill his moulds with the moist, soft mass, and presently take out the same "set" in the form given it by the matrix. Dentists use this material in taking casts of the jaws; decorators use it in ornamenting ceilings and cornices; sculptors use it in making the final model from which the marble statue is copied by skilled workmen who make that a profession.

Platæa (*pla-tē'a*), a city in the western part of Bœotia, on the borders of Attica and at the foot of Mount Cithæron, six miles from Thebes. In the year 480 B. C., it was destroyed by the Persians because the inhabitants had taken part with Athens in the battle of Marathon; but in the following year it was the scene of the victory won by Pausanias and Aristides over the Persians under Mardonius. During the third year of the Peloponnesian war, 429 B. C., it was besieged by a Theban and Spartan force, and heroically defended itself for more than two years until it was starved into surrender, the garrison of 200 men being put to the sword and the city razed to the ground. Such of the Platæans as escaped were hospitably received at Athens, and by the treaty of Antalcidas, forty years later, their children were allowed to go back and rebuild their city; but they were again driven out by the Thebans, and half a century elapsed before the victory of Philip at Chæronea enabled the Platæans finally to return to their homes.

Pla'teau, Joseph Antoine Ferdinand, a distinguished Belgian physicist, was born at Brussels in 1801, and died at Ghent in 1883. He was educated at the University of Liège, and was professor of physics at the University of Ghent from 1835 to 1883. His most important contributions to science are along two rather different lines, viz., subjective visual phenomena and capillarity. It was while engaged in the former study that he looked directly at the midday sun for 20 seconds in order that he might study its after effects. One of these "after effects" was that he became permanently blind in 1843. His work on surface tension was carried on, under his direction, by his wife and son and by his distinguished son-in-law, Van der Mensbrugghe. These researches are contained in his *Statics of Liquids* (1873) which has been translated into English by the Smithsonian institution. A more beautiful and ingenious series of experiments on surface tension than those here described it would be impossible to find. Plateau is to be remembered also as the inventor of the thaumatrope.

Plat'ing consists in covering the surface of a metal with a coating of a more valuable metal. Thus many metals and alloys are plated with gold or silver, and iron is frequently nickel-plated. The operation is performed most frequently by placing the object to be plated in an appropriate solution and causing the metal to be deposited by means of an electric current. In silver plating a

bath of silver cyanide dissolved in potassium cyanide is commonly used, while an anode of silver supplies this metal as fast as it is deposited upon the objects forming the cathode. Copper and zinc may be deposited at the same time upon iron objects, thus producing brass plating. In most cases electro-plated articles require rubbing or "burnishing" in order that they may acquire a brilliant luster.

H. L. WELLS.

Plat'inum is one of the "noble metals." It is generally found in small granules mixed with other metals, but sometimes in masses as large as a pigeon's egg — in rare cases pieces have been found weighing ten or more pounds. It is chiefly obtained from the Ural mountains, although it has also been found in Brazil, Colombia, California, Canada, and Borneo. Platinum is the heaviest form of matter known, except iridium and osmium. It expands less by heat than any other metal, and as it expands to about the same extent as glass, it is easy to fuse a wire of this metal into glass without causing the latter to break subsequently. Electric currents are thus led into the ordinary incandescent light bulbs. On account of its power of resisting the action of acids it is of great service in chemical experiments, platinum capsules, crucibles, etc., being found in every laboratory. Platinum is exceedingly malleable and ductile, but it melts only when subjected to the very highest degree of heat. On this account it is in great demand for electrical as well as chemical apparatus, and the recent introduction of the platinotype process in photography has run up the price from 35 cents per ounce in 1880 to about twice that amount at the present time.

Pla'to, a distinguished Grecian philosopher, was born during the early years of the Peloponnesian war, most probably about 425 B. C. A vast amount of detail has come down to us respecting his life, but most of it is very doubtful. According to one account, Plato was born in Athens; according to another, in the island of Ægina. He came of an aristocratic family, his father, Ariston, boasting descent from Codrus, the last king of Athens. In his youth, Plato indulged to some extent in writing poetry, but when he compared his various compositions with Homer, he abandoned the Muse entirely, and having when about twenty years old become acquainted with Socrates, he henceforth devoted himself to philosophy. His companionship with Socrates continued until the death of the latter, in the year 399 B. C. Plato made no attempt to enter on a political career. His youth was passed amid the disasters and failures of the Athenian democracy, and it is not likely that the martyrdom of his friend and teacher, Socrates, would favorably incline him to the democratic form of government. After the death of Socrates he went to Megara, where he remained some time, and afterward visited Cyrene, Egypt, Italy, and Sicily. Accounts of his visits to the Persians, the Babylonians, and the Hebrews are doubtless fictions of a later age, which supposed that wisdom could only come out of the east. On his way back to Athens, Plato is said to have been seized and sold as a slave in Ægina, but was ransomed by one Anniceris of Cyrene. On his return to Athens, about the year 388 B. C., he began to teach in the academy, a grove in the western suburb of the city, named from the hero Academus. There he gathered around him a band of disciples, teaching them mainly by questions and conversations, after the manner of his master Socrates. He twice visited Sicily, where he spent some time. Returning to Athens, he continued his work of teaching and writing until 347 B. C., when he died at a wedding feast in his eighty-first year.

The distinctive principles of the teaching of Socrates are the "inductive method" and the effort to get general definitions. When people spoke about persons or acts as just or beautiful, Socrates would ask, "What is justice?" "What is beauty?" and would test every definition brought forward by applying it to particular instances, content to remove misconception and error even when complete truth could not be obtained. This is the course pursued by Plato in his earlier dialogues; but in the *Theætetus* the Platonic Socrates asks the profounder question, "What is knowledge?" It is not "sensation," for sensation alone gives us no objective certainty. It is not "opinion," for opinion may or may not be true. A man only knows when he sees the reasons or causes of things; when he perceives facts as links in the chain of cause and effect. Man can only know that he knows when he deals with that which is permanent and universal. What then is this? Plato's answer is found in his theory of "ideas" or "forms." These are not material objects, but the everlasting essences, to be apprehended only by the reason; they are the substances of which material things are but the shadow. In our time they are generally described as "mental concepts." The form of a statue is not the marble out of which it is carved, but the thought or conception of the sculptor, of which the marble is only an expression. In his *Republic*, Plato elaborates his theory of knowledge and gives an illustration of it by picturing a majority of mankind as prisoners in a subterranean cavern chained with their backs to a fire, looking at the shadows thrown by it on the rocky wall and mistaking them for realities. The turning around of these prisoners to the light, their toilsome ascent up the steep slope to the mouth of the cave, the gradual training of their eyes to see the real things in the upper world, and then finally looking up to the sun itself, all this represents the education of the philosopher. Education is turning around the eye of the soul to the light. Learning, according to the *Meno* and *Phædrus*, is

"recollecting"; the soul in a previous existence has beheld the "ideas," or "forms"; and knowledge is possible because the mind does not acquire something alien to it, but recovers what is its own.

Philosophy to Plato was not mere intellectual speculation, but a habit of mind and a manner of living. The highest of the ideas in his view was "the good." While he does not accept the theory that pleasure is the good, neither does he agree with the cynics that all pleasure is evil. Pleasures are good or bad, high or low, according to the part of the soul to which they belong. Plato accepts without proof the popular distinction of four "cardinal virtues" — wisdom, the virtue of reason; courage, the virtue of the spirited element; temperance (*i. e.*, moderation, self-control in general), the virtue of the lower parts in their relation to the higher; and justice, the virtue of the whole soul.

In Plato's *Timæus* the cosmos, or order of the universe, is the "one only begotten image of God," its father and creator. The Creator being good, wished to make the world as nearly like Himself as possible; but no created or visible thing can be perfect. The material out of which the world was formed introduced evil into it. So also the Creator could not make the world eternal like Himself, and He therefore created Time, "the moving image of eternity." See Professor Jowett's translation of Plato. The doctrine of immortality is the main subject of the *Phædo*, and as the soul, according to Plato's philosophy, had an existence before the body, therefore it cannot be affected by the death and dissolution of the body.

Platt, Thomas C., an American business man and politician, famous as a leader of New York Republicans, was born at Owego, N. Y., July 15, 1833, and he has never acquired any other legal residence, although seldom in his birthplace except to vote. He studied at Yale college, but was not able to complete his course there on account of impaired health. He began business in his native village about 1855, but soon after became interested in lumbering in Michigan. The first public office he held was that of clerk of Tioga county. He was elected a member of congress in 1873–77, and United States senator in 1881. He resigned May 16, the same year with Roscoe Conkling. He was returned to the senate in 1897 for a period of six years. Mr. Platt has been actively engaged in many forms of business but has given most time to the affairs of the United States Express Co., of which he is president. He was the recognized leader of Republican political affairs in New York state for many years.

Platt'deutsch, or "Low Dutch," the direct descendant of old Saxon, is spoken to-day in different dialects by the peasantry of North Germany from the Rhine to Pomerania. Low German softens the consonants, but avoids the deep sibilants of high German as spoken in the south, and has simple grammatical rules. It is very appropriate in the mouths of the people who use it, their chief characteristics being a childlike good nature and sturdy honesty. Klaus Groth, Fritz Reuter, and other writers have given it a high literary standing.

Platte (or **Nebras'ka**), a tributary of the Missouri river, is formed by the junction of its north and south forks in western Nebraska. These forks, which rise among the Rocky mountains in Colorado, are 800 and 500 miles long, respectively, and neither of them is navigable. The general direction of the Platte is eastward in a wide, shallow stream over the plains of Nebraska till it reaches the Missouri river, after a winding course of over 400 miles. With its forks it drains some 300,000 square miles of territory, but like them it is not navigable.

Plautus (*plaw'tus*), **Titus Maccius,** the chief comic poet-dramatist of Rome, was born about 250 B. C. in Sarsina, a village in Umbria. We have no positive knowledge as to his early life and education, but it is probable that he came to Rome at an early age and acquired there his mastery of the most idiomatic Latin. At Rome, he found some kind of employment in connection with the stage and made money enough to set up in business for himself in the way of foreign trade. He, however, failed in business and returned to Rome in such poverty that he was compelled to earn his livelihood by turning a handmill, work usually performed by slaves. While engaged in this occupation, he wrote three plays, which proved so successful that from that time he was the favorite dramatist of his day. His plays were very popular, not only with the common people, but also with the educated classes, and were acted in the time of the Emperor Diocletian, five centuries later. The scenes of his comedies are always laid in Athens or in some other Greek town; but his Greek characters speak and act like Romans. Shakespeare himself is not more careless about inconsistencies of this kind. The charm of Plautus lies in his genuine humor and grasp of character. He goes down to the very depths of human nature, and delights his readers to-day as truly as when he made the Roman theatres ring with applause, or when St. Jerome solaced himself in his cell by reading the well-loved comedies. Shakespeare has imitated the plot of the *Menæchimi*, entirely recasting it in his *Comedy of Errors*. He died in 184 B. C. See *Roman Poets of the Republic*, by Sellar.

Play'fair, Lord, formerly known as Sir Lyon Playfair, an English chemist and statesman, was born at Meerut, India, May 21, 1818 but educated at St. Andrews university, Scotland. He early became interested in the study of chemistry, to which he devoted

himself assiduously, going to Germany in 1838 to study under Baron Liebig. He was appointed manager of the great calico-print works at Clitheroe, Lancashire; and in 1844 professor of chemistry in the Royal institution, Manchester. Under Sir Robert Peel he was made commissioner to examine into the sanitary condition of the chief cities of Great Britain. In 1851, he was made special commissioner in charge of the department of juries in the first World's Fair, the exhibition of 1851, being made a Companion of the Bath for services rendered. He had also offices in connection with the expositions of 1862 and 1878 (Paris). He served ten years as professor of chemistry in the University of Edinburgh, and in 1868 he was elected to parliament to serve for both the universities of St. Andrews and Edinburgh, holding a seat at Westminster for seventeen years. He was postmaster-general, deputy speaker of the house, and vice-president of the council at various periods. He was lord-in-waiting to the queen, and counsel to the Prince of Wales. In 1883, he was made a K. C. B. In 1885, he was president of the association for the advancement of science. He was raised to the peerage as Baron Playfair of St. Andrews in 1892. He was the author of various works upon his chosen profession and edited an edition of *Liebig's Chemistry in Its Application to Agriculture and Physiology*. He died at London, May 29, 1898.

Plays. See DRAMA.

Pleas'onton, Alfred, an American general, was born in the District of Columbia in the year 1823, and graduated at West Point in 1844. He served under General Taylor in the Mexican war, gaining the rank of brevet first-lieutenant at the battles of Palo Alto and Resaca de la Palma. After the Mexican war, he continued to serve in the regular army until the Civil war broke out, when he was appointed major of the 2d United States cavalry. He was appointed brigadier-general of volunteers by President Lincoln, July 16, 1862, and as commander of a cavalry division rendered valuable service in the army of the Potomac at Boonsborough, South Mountain, Antietam, Fredericksburg, and Chancellorsville. As chief of cavalry he also took an active part in the engagements with Lee's forces preceding the battle of Gettysburg. The next year (1864) he was transferred to Missouri, where he displayed his accustomed vigor and ability in driving the Confederate forces from the state. He resigned his commission in the regular army in 1868, after which he filled the office of commissioner of internal revenue for several months during General Grant's administration. General Pleasanton afterward resided in Washington city. He died at Washington, D. C., Feb. 17, 1897.

Pleiades (*plē'ya-dēz*), **The,** in Greek mythology, were, according to the most general account, the seven daughters of Atlas and Pleione. According to some accounts, they committed suicide from grief, either at the death of their sisters, the Hyades, or at the fate of Atlas, their father; according to others they were companions of Diana, and being pursued by Orion, were rescued from him by the gods by being translated to the sky; all authorities, however, agree that after their death or translation they were transformed into stars. Their names are Electra, Maia, Taygeta, Alcyone, Calæno, Sterope, and Merope. The group of the Pleiades, called the "Seven Stars," is placed on the shoulders of Taurus, the second sign of the zodiac, and form with the pole star and the twins, Castor and Pollux, the three angular points of a triangle.

Ple'rome (in plants). At the growing tip of a stem or a root the great regions are organized in embryonic form. In both stems and roots there are three such regions. On the outside is "dermatogen" (which see), which gives rise to the epidermis; within the dermatogen is the "periblem" (which see), which gives rise to the cortex; within the periblem and forming the central axis of the stem or root is the "plerome," which gives rise in the mature stem or root to what is known as the "stele," in which the woody bundles arise. A longitudinal section of an ordinary root or dicotyledonous stem will reveal these three great regions. Of course the pith which exists within the woody cylinder of the stem is a part of the stele.

Plin'y the Elder, so called to distinguish him from his nephew of the same name, was born either at Novum Comum (the modern Como), or at Verona, in the year 23 A. D. His education was carried on at Rome under every advantage that wealth could furnish, and at the age of twenty-three he entered the army, serving on the staff of L. Pomponius Secundus, then conducting a campaign in Germany. Returning to Rome, in 52, he practiced at the bar for a short time, and then withdrew to Como, where, during the greater part of the reign of Nero, he devoted himself to reading and authorship. Toward the close of Nero's life he was appointed procurator (collector of revenues) in Spain, and remained there until the year 71, when he returned to Rome to prosecute his studies and to assume the guardianship of his nephew, Pliny the Younger. By incessant and lifelong application he amassed materials enough to fill the 160 volumes of manuscript which he bequeathed to his nephew. His *Historia Naturalis*, in 37 books, is the only one of his works that has come down to us. Under that title the ancients classified everything of natural origin, not only botany, zoology, and mineralogy, but geography and astronomy. Pliny, however, extends this list by comments on human inventions and institutions, and even devotes two books to a history of fine art.

Pliny was in command of the Roman fleet off Misenum when the great eruption of Vesuvius occurred, in 79 A. D. Eager to witness the phenomenon as closely as possible, he landed at Stabiæ, but had not gone far toward the mountain when he was suffocated to death by the stifling vapors and cinders with which he came in contact.

Plin'y the Young'er was born at Novum Comum (Como), Italy, in 62 A. D. His education, after his tenth year, when his father died, was conducted by his mother, his uncle Pliny the Elder, and his tutor Virginius Rufus. He early manifested the highest literary talents, and made such progress that in a few years he was known as one of the most accomplished men of his time. When only eighteen he began to plead in the forum; and at twenty-five, the earliest possible age, he was quæstor Cæsaris, then prætor, and in the year 100 was chosen consul, in which year he wrote his panegyric on the Emperor Trajan. He was twice married, but died without issue, in what year is not known. It is to his letters that Pliny owes his place in literature. An avowed imitator of Cicero, he has caught much of the charm of his model, while his style is hardly, if at all, inferior. We derive from him our impressions of the public and private life of the upper classes in the 1st century; and from his correspondence with Trajan we get our clearest knowledge of the feeling with which even one of the most enlightened Romans regarded the then obscure sect of Christians. Pliny consulted the emperor as to what could be done to stop the spread of what he called "a depraved and extravagant superstition," and in reply Trajan recommended that Christians should not be sought out on suspicion, but that if accused and convicted of holding that faith, they should be punished. Accusations unsupported by proof were not to be received, while suspected persons were to have an opportunity of clearing themselves by offering prayers to the Roman gods. He died in 113 A. D.

Plow, an instrument for breaking up and turning over the soil preparatory to the raising of a crop. The plow is mentioned in the Old Testament as having been used at a very early period; and Dr. E. B. Tylor, in his *Anthropology*, has clearly shown how it arose by gradual improvement from the hoe as that did from the pick or hatchet. The modern plow, with its mouldboard for turning over the soil, was invented in the Netherlands a little more than two centuries since; but it has been greatly improved in that time. England took the lead in this improvement, followed by Scotland, in which country the chief inventors and improvers were Small (the inventor of the Scotch swing plow), Wilkie, Gray, and Sellar. In the American sulky plow the weight of the implement is supported by wheels, thus decreasing friction and enabling the plowman to ride on the plow, instead of walking. The double Michigan plow has a small plow on the beam in front of the other. The small plow pares off the surface of the soil and throws it into the previous furrow, and the large one completely buries it under a heavy furrow slice. Reversible or sidehill plows have the share and mouldboard so they can be easily changed from one side to the other. Steam plowing, although first introduced in England in 1832, is yet in its infancy; but it is reasonable to assume that ere long it will be a very common method of breaking the soil, especially on the prairie land of the United States.

Plover (*plŭv'er*), a shore-bird with long wings and slender legs, related to the snipe. There are about one hundred species of plovers, but only six are found in eastern North America. They live mostly near the water, but some forms visit uplands and dry fields. The killdeer is the one most generally known. It and the piping plover are the only ones that nest in the eastern United States. It is about 10½ inches long, with the upper parts brownish-gray and the tail rusty. The white breast

GOLDEN PLOVER.

is crossed by two dark bands which is its best field mark. The ring-necked plover looks like a small killdeer. It is about 6¾ inches long, with a single black bar across the breast. It visits our shores on its way north in May, and, again, in August and September on its journey south. It is so small it is not shot as game. Besides the two mentioned, those less frequently seen in eastern North America are, the golden, piping, black-breasted, and Wilson's plovers. The lapwing of Europe is a plover.

Plucker (*plŏk'er*) **Tube,** a long slender glass tube, first made by Geissler of Bonn (1858) on the suggestion of Plücker, for the examination of the spectra of gases. The original form of these tubes is shown in the accompanying figure. At each end a platinum

wire is sealed in; and when these wires are connected to the terminals of an induction coil, the electric discharge brings the gas to incandescence, so that its spectrum is then ready for examination by the spectroscope. An improved form of spectrum tube is one in which the capillary portion is placed "end on" instead of "side on" before the slit of the spectroscope. See Kayser's *Handbuch der Spectroscopie*.

PLÜCKER TUBE.

Plum, certain species of the genus *Prunus* to which also belong the peaches and cherries. In the plum the flowers occur in umbel-like clusters and appear either before or with leaves. The fruit is a drupe or stone fruit, as in the case of peaches and cherries. The most common plum of cultivation is *P. domestica*, which is probably of Asiatic origin. Its fruits have been made to vary exceedingly as to shape and flavor. The common wild plum of the United States is *P. Americana*, with dull yellow fruit, splashed with spots of red, which is also under cultivation. The wild goose plum is *P. hortulana*, with many varieties under cultivation. It is found wild in the Mississippi valley.

Plumb, Preston B., United States senator from Kansas, was born in Delaware county, O., Oct. 12, 1837, and removed to Kansas in the year 1856. In 1861, he commenced the practice of law in that state, but the next year was commissioned second lieutenant in the 11th Kansas infantry, in which he rose to the rank of colonel. In 1877, he was elected to the United States senate, and continued an active and useful member of that body until his death, which took place Dec. 20, 1891.

Plumule (*plū'mūl*) (in plants), the first terminal bud which appears in the embryos of most dicotyledons. Sometimes it is very minute, in other cases it contains a number of the early leaves of the plant, and in any case it develops the shoot. See EMBRYO.

Plu'tarch, a prolific author of the first century, was born at Chæronea in Bœotia, in 46 A. D. Scarcely anything is known of his personal history, except that he commenced to study at Athens under the academic philosopher Ammonius in 66, the year of the Emperor Nero's progress through Greece. He also spent several years at Rome, where he enjoyed the friendship of public officers and men of learning, besides devoting himself to a course of study and giving lectures on philosophy. The story that he became Trajan's preceptor and was raised by that emperor to the consulship, is hardly to be credited. Life at Rome not being altogether to his taste he returned to Chæronea, where he became a magistrate, and died at the advanced age of 70 or 75 years, in the reign of the Emperor Hadrian.

The work of Plutarch for which he is most noted is his *Parallel Lives*, in which he gives us the life of some distinguished Greek and some distinguished Roman, and then draws a detailed comparison between them, although some authorities consider these comparisons spurious. These lives, 44 in number, as arranged in pairs, are as follows: 1. Sertorious and Eumenes. 2. Cimon and Lucullus. 3. Lysander and Sulla. 4. Demosthenes and Cicero. 5. Agis and Cleomenes. 6. Pelopidas and Marcellus. 7. Phocion and Cato the Younger. 8. Aristides and Cato the Elder. 9. Pericles and Fabius Maximus. 10. Nicias and Crassus. 11. Dion and Brutus. 12. Timoleon and Æmilius Paulus. 13. Philopœmen and Titus Flaminius. 14. Themistocles and Camillus. 15. Alexander and Cæsar. 16. Agesilaus and Pompey. 17. Pyrrhus and Marius. 18. Solon and Valerius Publicola. 19. Demetrius and Antonius. 20. Alcibiades and Coriolanus. 21. Theseus and Romulus. 22. Lycurgus and Numa. Plutarch was not a profound thinker, but he was a man of rare gifts, and adheres throughout to his professed purpose, which was portraiture of character. For this reason his *Lives* will remain the book of all ages, so that Plutarch may almost be called the interpreter of Greece and Rome to modern times. As a moralist he is a man of practical views and sober judgment — a bright example of the illumination of the intellect by the power of morals. In his style he is picturesque, realistic, and varied, his chief fault being a tendency to diffuseness and redundancy of expression. See Sir Thomas North's version of *Plutarch's Lives*.

Plu'to, the surname of Hades, in Grecian mythology, is the third son of Cronos and Rhea, and the brother of Zeus and Poseidon. To him belongs the sovereignty of the under world — the realm of darkness and ghostly shades — where he sits enthroned as a "subterranean Zeus," and rules the spirits of the dead. His dwelling place, however, is not far from the earth. Pluto is inexorable in disposition, not to be moved by prayers or flatteries, and is borne on a car drawn by four black steeds, whom he guides with golden reins. In Homer, Hades means a person, not a place; and it is to be noticed that the poet does not divide the realm of the shades into two distinct regions. All the souls of the dead — good and bad alike — mingle together. At a later day the kingdom of the dead was divided into Elysium, the abode of the good, and Tartarus, the abode of the wicked. This change also exercised an important influence on the ancients' conception of Pluto. The ruler of the under world not only acquired additional power and majesty, but he was also regarded as a beneficent deity, who held the treasures of the earth (whence his name

Pluto, from *plutein*, "to be rich") in his hands, and who caused the fruits and abundance of the earth to spring from the under ground. Hence in later times men prayed to him before digging for the wealth hid in the bowels of the earth.

Plym'outh, an English seaport on the north shore of Plymouth sound, 240 miles from London and 125 miles from Bristol. Although at the time of the Norman conquest Plymouth was only a fishing village, under the name of Sutton, it has played a leading part in the history of England for several centuries since that time. It was the favorite port of Edward the Black Prince, the chief rendezvous of Drake, Hawkins, Grenville, Raleigh, and their fellows, and the final port of departure of the Pilgrim fathers in the *Mayflower*. In the contest of Charles I. and the parliament, it sided with the latter, and after enduring a series of sieges and blockades, extending over four years, shared with Hull the honor of saving the parliamentary cause. In the reign of James II. it was the first town to declare for the prince of Orange, and in the great French war it rivaled Portsmouth in naval activities. Population 102,000.

Plym'outh, Mass., on Plymouth bay, 37 miles by rail from Boston, is famous as the landing place of the Pilgrim fathers, Dec. 21, 1620. Plymouth Rock, on which they landed, is a granite bowlder at the water's edge and is covered by a handsome granite canopy. The pedestal, on a hill overlooking the landing place, is 46 feet in height, and is surmounted by a central figure of Faith, with four immense stone figures, representing Morality, Education, Freedom, and Law, around the base. In Pilgrim hall are preserved many relics of the first settlement of the country. The town is popular as a summer resort. Population 9,592.

Plym'outh, Pa., a borough on the Susquehanna river, the county seat of Luzerne county, four miles from Wilkesbarre, and in the center of the anthracite coal-mining activities. It is served by the Delaware, Lackawanna, and Western railroad. It has a number of public and high schools, churches, banks, and other civic institutions. Its chief industry is the shipping and handling of coal, as it is in communication, both by water and rail, with Scranton and the mines of Wilkesbarre. Population 13,649.

Plym'outh Sound, on the southwest of Devonshire, England, is a deep inlet of the English channel into which the river Tamar falls from the west, and the river Plym from the east. In 1812, was begun the construction of the Plymouth Breakwater, which is an insulated mole of stones, a mile in length, stretching across the middle of the sound, and thoroughly protecting all vessels anchored within. It was not fully completed till 1841, and cost nearly $7,500,000. Plymouth sound has been said to rival the bay of Naples in beauty. On its western shore is Mount Edgcumbe, the delightful seat of the earl of that name, said by tradition to have been selected by Medina Sidonia as his share of the English spoil. Rame Head, crowned by the ruins of a mediæval chapel, is one of the most picturesque headlands on the coast; and the estuary of the Yealm, with the peaked Mewstone at its mouth, is full of romantic beauty.

Pneumat'ic (*nū-măt' ĭk*) **Tool,** a mechanical tool operated by compressed air. In tunneling and mining, pneumatic drills are used, and similar tools are used for stone carving. The power is applied by pressure of compressed air against a piston, in a cylinder, and by a suitable automatic valve the blow can be repeated several times per minute. Pneumatic riveting machines and hoists are two other pneumatic tools used very extensively. Pneumatic tools are generally simple to operate, but not so economical as either steam or electricity.

Pneumat'ic Tube, a tube or pipe in which packages and written messages are sent by the use of compressed air, or by normal atmospheric pressure acting against a vacuum. The packages are inclosed in carriers of proper shape or size to go into the tube and are forced along the tube by pressure behind them. Pneumatic dispatch is used very extensively in large stores, in connection with "cash systems." In newspaper and telegraph offices it is used to transmit messages. In New York city, London, and several other large cities, it is used to send the mails between the main post office building, the sub-stations, and the railroad stations. In Berlin and several continental cities, it has been used for rapid delivery of local letters in connection with the post office. Lead pipes are ordinarily used for messages, but steel pipes are used for large packages.

Po, the largest river of Italy, rises on Monte Viso, one of the Cottian Alps, at an altitude of 6,000 feet, close to the French frontier. About 60 miles from its mouth, above Ferrara, it begins to form its delta, 60 miles wide from north to south. The delta is rapidly growing in area; Ravenna, once a city on the seashore, is now four miles inland. The entire length of the Po is 360 miles, and it drains an area of 28,900 square miles. It has always been a difficult river to cross on account of its width and the great volume of its waters; hence the commercial importance of such places as Piacenza and Turin, where there are the easiest fords.

Pocahon'tas, daughter of the Indian chief Powhatan, was born about the year 1595. Her name has become famous for the part she is said to have played in saving the life of Captain John Smith in the year 1607. In one of Smith's exploring expeditions in Virginia, he was taken prisoner by the Indian chief Pow-

hatan, and his head laid on a log preparatory to having his brains beaten out by a club. At this juncture, Pocahontas rushed between Smith and her father, and placing her head on that of Smith, persuaded Powhatan to spare his life. Pocahontas married an Englishman named John Rolfe, in 1614, and went to England with her husband two years later. After remaining in that country six or seven months, she embarked for Virginia, and died off Gravesend in March, 1617.

Pod the general name applied to dry and dehiscent fruits. A pod may be made up of one or more carpels. It is also used as the special name of a dry elongated fruit which consists of a single carpel, as in peas and beans. See FRUIT.

Poe (*pō*), **Edgar Allan,** an American poet, was born at Boston, Jan. 19, 1809. His father and mother both dying in his infancy, he was adopted by John Allan, a rich and childless merchant of Richmond. In 1826, he entered the University of Virginia at Charlottesville, but although a brilliant and successful student, he quitted the institution at the end of a year, deeply involved in debt through his passion for gaming. After remaining at home a year or more, he expressed a desire to enter the military profession, and Mr. Allan secured his appointment as a cadet at West Point. Here he drank to excess and so neglected his duties that he was court-martialed and dismissed in the year 1831. He returned to Richmond and was kindly received by his foster-father, who had become a widower and married a second time. It is related that Poe's conduct toward Mrs. Allan was such that he had to be driven from the house. Whether this were the case or not, when Mr. Allan died, in 1834, Poe was not mentioned in his will. Thus thrown upon his own resources for a livelihood, Poe devoted himself to literature. In 1833, the publisher of a Baltimore magazine offered prizes of $100 each for the best poem and the best prose story, both of which were won by Poe. About the same time he secured employment in connection with the *Southern Literary Messenger* at Richmond, and while there married his cousin, Virginia Clem, a beautiful and saintly girl only fourteen years old, who died in 1848. In 1837, Poe moved to New York, where he spent the next few years in various kinds of literary labor, the year 1845 being marked by the appearance of his world-famous poem, *The Raven*. In 1849, he visited Richmond, where it is said he became engaged to a woman of considerable fortune. On the 4th of October he left Richmond for Baltimore, and a few hours after reaching the latter city he was found insensible on the street and taken to a hospital, where he died two or three days later (Oct. 7, 1849). In all the sad records of genius, there is hardly any such dark and disastrous career as that of Poe. Highly gifted as he was in intellect, his moral sense seemed fatally defective. One of his most intimate acquaintances pronounced him, "characterless" and "utterly deficient in high motives." Even his love for his devoted wife could not restrain him from indulgence in the brandy and opium that were working his ruin. There is considerable dispute as to the *degree* of Poe's immorality and degradation of character, and it is certainly to be hoped that some of the pictures drawn of him are greatly exaggerated. But whatever may be said of his morals, his genius must be conceded to be of a high order. Small in quantity and limited in range as is his poetry, there is yet that in it which gives it a high place in American literature, and will cause it to be read and admired by many generations.

Poerio (*po-ā'rē-ō*), **Carlo,** an Italian patriot, was born at Naples, Dec. 10, 1803, his father being a Neapolitan lawyer who had suffered imprisonment and exile in the cause of liberty. He accompanied his father into exile, but on his return became an advocate at Naples. He was frequently imprisoned for his services to the liberal cause; and on the 19th of July, 1849, he was arrested, charged with being a member of a secret society, the Italian Unity, and condemned to imprisonment at hard labor for twenty-four years. With fifteen others, he was confined in one small chamber in the island prison of Nisida. He was afterward moved to other prisons, but was still treated with great rigor and severity. At length, however, there were such protests from other European governments, that Ferdinand II. consented to ship over sixty of his prisoners to America. They persuaded the captain of the vessel to land them at Cork, and Poerio returned by way of London to Turin. There he became a member of parliament, and in 1861 its vice-president. He died at Florence, April 28, 1867.

Po'etry (from the Greek word *poieo*, "to make" or "create"). A complete definition of poetry is impossible, its higher spiritual qualities defying analysis and description. According to the etymology of the word, it signifies a production or creation of any kind; but in actual use it applies to the products of the *imagination* and to the form or language in which they are expressed. Here the critics differ as to whether any composition should be called poetry unless it is constructed in regular measure or meter—that is, whether it must be poetic in form as well as in essence. Certain it is that our literature as well as the literature of other nations abounds in works highly imaginative and composed in truly poetic language, but which are generally called prose works, because their form has not been reduced to meter or rhyme. The book of Ruth in the Old Testament is decidedly poetical in its substance, but prosaic in form, and the same may be said of the book

of Job and the writings of the prophets. But whether we consider rhyme and meter essential to poetry or not, they greatly increase not only its beauty but its effect. The reason of this is that the music of the words so arranged heightens the emotions produced by their meaning, and thus furthers the end that the poet has in view; and so the poet is ever a "maker" as well as a singer. But, on the other hand, neither meter alone nor meter and rhyme combined will constitute poetry, unless there be truly poetic thought clothed in poetic language. The three principal kinds of poetry are the epic, the lyric, and the dramatic. The first of these refers in general to poems that are to be read or recited, not sung. It includes matters of narration, real or fictitious, philosophical reflections, etc. Lyric poetry includes the song in all its varieties, the hymn, the ode, the anthem, the sonnet, etc. Dramatic poetry embraces tragedy and comedy. In actual poetic composition, the distinction between these divisions of poetry is not always clear, as each one of them frequently contains elements belonging to the others.

Pog'gendorff, Johann Christian, an eminent German physicist, was born at Hamburg, Dec. 29, 1796; and died at Berlin, Jan. 2, 1877. He is best known, perhaps, in his capacity as editor of the great German periodical *Annalen der Physik und Chemie*, a position which he held from 1824 until his death in 1877. More than half a century of editorial supervision prepared him in an exceptional manner for the course of lectures which he delivered, in Berlin university, on the history of physics, and which were published in 1879 as a posthumous volume. Poggendorff's contributions to physics were all on electrical subjects. He devised the telescope and scale for reading galvanometers, and besides must be reckoned as one of the inventors of the galvanometer. He devised also an elegant null method for measuring the electromotive force of a voltaic cell.

POINTER.

Poi'sons. A poison may be defined as "any substance or matter which, when introduced into the body in any way, can destroy life by its own inherent qualities without acting mechanically." Poisons are sometimes classified according to their source as mineral, vegetable, and animal, or more generally, according to their action as *irritants*, *narcotics*, and *narcotico-irritants*. The irritants, when taken in ordinary doses, produce intense vomiting and purging and severe abdominal pain. They act directly upon the stomach and intestines, which they inflame and frequently corrode. The narcotics act specially on the brain and spinal cord. Among their most common symptoms are headache, giddiness, obscurity of sight, stupor, loss of muscular power, convulsions, and finally complete coma. They have no acrid, burning taste, and except a slight fullness of the cerebral vessels they leave no clearly marked post-mortem appearance. The narcotico-irritants have a mixed action. At varying periods after they have been swallowed, they produce stupor, coma, paralysis, and convulsions, owing to their effect on the brain and spinal marrow. As examples of irritant poisons we may mention sulphuric, nitric, and oxalic acids (in doses of half an ounce or more), carbolic acid, arsenic, corrosive sublimate, blue vitrol, lunar caustic, and chloride of antimony. Among the narcotics are opium, belladonna, alcohol, ether, India hemp, chloral, chloroform, etc. The narcotico-irritants include prussic acid, strychnine, nux vomica, hemlock, aconite, nicotine (the active principle of tobacco), etc. The evils resulting from the use of alcohol in its various forms have caused laws restricting or prohibiting the sale of intoxicating liquors to be passed in most of the states of the Union; and as a preventive of the evils resulting both from alcohol and tobacco, nearly all the states have laws providing for instruction in the public schools as to the effect of narcotics upon the brain and nervous system.

Poi'son Ivy. See Sumac.

Poisson (*pwä-son'*), **Simeon Denis,** an eminent French mathematical physicist, was born at Pithiviers, June 21, 1781; and died at Paris, April 25, 1840. He was educated at the *École Centrale* at Fontainebleau and at the *École Polytechnique* at Paris. It was at the latter institution that he came under the influence of, and soon commanded the attention of, two very powerful teachers, Lagrange and Laplace. In 1802, only four years after entering, he found himself professor of analysis and mechanics in the *École Polytechnique*. In 1812, he was elected to the Academy. Poisson was a staunch Republican and accordingly little in favor with the government during the régime of Napoleon; after the Restoration, however, he was much honored. Among his most important works must be mentioned, in pure mathematics, his contributions to the Calculus of Variations and to the Theory of Probabilities; in astronomy, his proof of the stability of the Solar System; and in physics his very important theorems in

electrostatics, and in fluid motion his theory of capillarity, and his mathematical theory of heat. His treatise on *Mechanics* (2 vols., Paris, 1811) was a standard text-book on this subject for half a century. See Arago's *Notices Biographique*, Vol. 2.

Poitiers (*pwa-tē-ā'*), a city of France, occupying the summit and slopes of a hill at whose base flow the Clain and Boivre rivers. Before the French revolution it had a large number of religious edifices, which even yet are quite numerous. Within and about the city are numerous Roman and Celtic remains, a dolmen, baths, and some fragments of an amphitheatre; and here, in 1882, the remains of an entire Gallo-Roman town were discovered, with temple, baths, and streets spread over fourteen acres. In the vicinity of Poitiers, Alaric II., the Visigoth was defeated and slain by Clovis in 507, and between Poitiers and Tours, Charles Martel won his great victory in the year 732, over the Saracens under Abd-ur-Rahman. Later still, Sept. 19, 1356, about five miles north of the city, Edward the Black Prince, with only 12,000 or 14,000 English and Gascon troops, defeated about 60,000 of the troops of King John of France, killing 11,000 and taking more than 2,000 prisoners. Population of Poitiers, 38,519.

Po'land (called by the natives *Polska*, a word of the same root as *Pole*, "a plain"), a former kingdom of Europe, was, before its partition by Austria, Russia, and Prussia, bounded on the north by the Baltic sea and the Russian provinces of Riga and Pskof; on the east by the Russian provinces of Smolensk, Tchernigoff, Poltava, and Kherson; on the south by Bessarabia, Moldavia, and the Carpathian mountains; on the west by the Prussian provinces of Silesia, Brandenburg, and Pomerania. Its greatest length from north to south was a little more and from east to west a little less than 700 miles, embracing an area of about 280,000 square miles. This extensive tract is crossed by only one range of hills, which rises from the north side of the Carpathian mountains and runs northeast, forming the watershed between the rivers which flow into the Baltic and the Black seas. Much of the soil is rich pasture-land, and considerable is occupied with forests of pine, birch, oak, etc. There is no real Polish history till the reign of Mieczyslaw, 962–992. He became a convert to Christianity, and Poland took her place as one of the political powers, which she continued to hold till the close of the 18th century, when her independence was destroyed and her territory divided between Austria, Russia, and Prussia. The first partition of Poland took place in 1772, when Russia seized 42,000 square miles of her territory, Prussia 13,000, and Austria 27,000. In 1793, after a fruitless resistance to the united forces of Russia and Prussia, Poland suffered another loss of territory, Russia taking possession of 96,000 square miles, and Prussia of 22,000. The Poles now became desperate, and there was a general uprising of the people against the invaders. The Prussians were compelled to retreat to their own country, and the Russians were several times routed. But Austria again engaged in the contest, and fresh Russian troops also arrived. Kosciusko being defeated and taken prisoner at the battle of Maciejowice, the Russians entered Warsaw (1813), and the Polish kingdom came to an end. In the third and last partition of Poland, the remainder of the country was divided as follows: Russia, 49,159 square miles; Prussia, 21,000; Austria, 18,000. King Stanislaus resigned his crown, and died at St. Petersburg in 1798. The main causes of the downfall of Poland, in addition to the greed and selfishness of the European powers, were: 1. The want of union and patriotism among the nobles. 2. The want of a national middle-class, the trade of the country being almost entirely in the hands of the Jews and Germans. 3. The intolerance of the Jesuits. 4. The weakness of the kings. 5. The want of natural frontiers. To-day Poland forms a government department of Russia, embracing ten provinces, and a population of 9,456,000. In 1864, it was deprived of its administrative independence, and in 1868 was incorporated as an integral part of the Czar's dominions; trial by jury was at the same time abolished, and the official use of the Polish tongue prohibited. In this region, there are two main parties, both equally opposed to Russian government, viz., the Nationalists and the Socialists.

Po'lar Bear. See BEAR.

Po'lar Circle. See ARCTIC CIRCLE.

Po'lar Ex'plora'tion. The original motive of the English in exploring the arctic seacoast was to discover a route to the wealthy countries of eastern Asia, and to share in the traffic formerly monopolized by Spain and Portugal. Thus arose attempts both to sail eastward along the north of Europe and Asia, and westward across the Atlantic. Hence arose the terms, "northeast passage," and "northwest passage." Some have traced the history of arctic exploration to the time of King Alfred, but Cabot's discovery of Labrador and Newfoundland, in 1497, may be deemed the first step in the exploration of American polar regions. Frobisher first sailed in 1576, and in 1585–88 the great navigator Davis sailed up the strait bearing his name and coasted the west of Greenland, the "land of desolation." Hudson, who had formerly tried the northeast passage, discovered, in 1610, the great bay and strait that bear his name. From the size of the bay he thought it was a part of the Pacific ocean, but this was disproved by Button, the next English explorer, two years later. After the expedition of Fox and James, in 1631, which led

only to the partial exploration of what was then named Fox channel, the North American coast was neglected for more than a century. In the reign of George III., there was a revival of English zeal in naval adventure and discovery. Captain Phipps (afterward Lord Mulgrave) sailed, in 1773, to Spitzbergen, where the heavy pack ice kept him for nearly a month from proceeding further north. He finally reached 80° north latitude, but Cook, who made the next attempt, could only penetrate to 70°45′. After these failures there was no further effort made until 1806, when Scoresby explored Jan Mayen island and the east coast of Greenland. The famous expedition of Sir John Franklin left England, May 18, 1845, his object being to reach Bering strait from Lancaster sound. In 70° north latitude and 98° west longitude, the ships were beset, and Franklin died in 1847. Among the expeditions sent out in search of Franklin was that of Collinson and McClure, which sailed from Plymouth to Bering strait in 1850. Fixed in the ice on its voyage eastward, McClure's ship was rescued the next spring about 60 miles west of Barrow strait. Belcher now turned toward the Atlantic, and thus McClure reached England in 1854, after traversing the northwest passage from ocean to ocean. He therefore received the honor of knighthood, and the sum of $50,000 was voted by parliament to him and his crew. Several routes are now completely mapped between Davis strait and Bering strait; but the northwest passage has proved of no value whatever for commercial purposes.

The more recent explorations to the north of America have added little to our geographical knowledge, however interesting they may be in certain scientific aspects. The expedition of Kane and Hayes, in 1853–55, reached in sledges Cape Constitution, in 82° north latitude, and saw what appeared to be an open polar sea. In 1871, the *Polaris*, under Captain C. F. Hall, sailed from New London, United States, and reached 82° 16′ north latitude, which was surpassed, in 1876, by the English expedition under Captain Nares. More famous and more disastrous was the "Lady Franklin Bay expedition," of 1881, under Lieutenant Greely. In October, 1883, Greely and his brave companions landed at Cape Sabine, probably the bleakest spot in all the Arctic regions, and there, in June, 1884, Commander Schley found the six men who still survived. In 1869–70, Captain Coldewey's expedition reached 77° north latitude on the east coast of Greenland, the highest latitude yet attained on that coast. The *Jeannette* expedition, under Commander De Long, sent out by the New York *Herald*, in 1879, to push north by Bering strait, ended in disaster, the vessel being crushed in the ice, in June, 1882. The latest expedition to the Arctic regions was that of Lieut. Robert E. Peary, U. S. N., which set out in the *Kite*, June 6, 1891. Reaching McCormick bay, July 24, winter quarters were established there; and the months from August to May were spent by Peary, and a handful of men, in exploring the north of Greenland by an overland journey of over 600 miles on the inland ice, while the *Kite*, commanded by Heilprin, held on its way by sea. In September, 1892, the expedition returned, having determined the northern boundary of Greenland, which is truly an island, not reaching beyond 83° north latitude.

In 1893, R. Knudsen made important corrections in the charts as to the east coast of Greenland, from his personal inspection in the neighborhood of the 68th parallel. Nansen (Fridtjof) crossed the ice-cap of the continent from east to west, in 1888, rising to a height of 9,000 feet upon the divide. Lieutenant Peary, in 1886, advanced fifty miles inland from Disco, on the ice-cap, and made his winter quarters at McCormick bay, about 77° 45′ N., 71° W.; and starting for the further north, May 14, 1892, he reached Navy Cliff, July 4, Independence bay, in 81° 37′ N. In 1895, Peary made an attempt to improve upon this record, but, after reaching Independence bay, he was reduced to such straits for lack of food as to be obliged to abandon the attempt. A noteworthy attempt to reach the pole was made by Captain Nansen, who, having constructed a ship, the *Fram*, after his own designs, permitted it to be frozen into the ice-pack of the Kara sea, in 1893, and with the ice his ship was drifted across the frozen seas which lie about the pole. He had hoped to come out of the ice between Iceland and Spitzbergen; but, the ice-pack not floating so far north as he had supposed, he left the ship and sought to go further on foot. At last he was obliged to turn back; and he reached Franz Josef Land, in 1895, and returned to Norway in 1896. The "furthest north" reached by Nansen was 86° 14′. The Duke of Abruzzi, who sailed from Christiania, June 12, 1899, is reported to have reached a point 19 geographical miles nearer the goal sought. In 1900, Lieutenant Peary sailed with still another expedition, and is still in the frozen seas, report of favorable progress having been received from him in September, 1901. A very fully-equipped expedition sailed from Tromsö, Norway, in command of Lieutenant Evelyn Baldwin, in June 1901.

Few attempts to penetrate the unknown regions of the southern, or antarctic pole, were made after the expeditions of Wilkes, d Urville, and Ross (1839–43), until of recent years. Knowledge of these regions is valuable only from a scientific point of view. But in the summer of 1892, Captain Larsen, of the Norwegian ship *Jason*, discovered, in latitude 64° 10′ S., 57° W., fossils which interested him as showing that the antarctic regions were once covered by coniferous trees. The next year Captain Larsen led an expedition through this region, reaching a point 68° 10′ S. and 60° W. The coasts were high, rocky, and mostly covered with ice. In 1894, Captain Svend

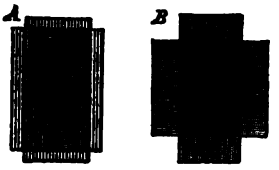
Foyn, in the whaler, *Antarctic*, visiting the southern seas in search of whales, reached a point 74° S.; Jan. 23, 1895, a landing was made at Possession island, where innumerable penguins were found nesting. The first vegetable growth (a lichen) ever found within the antarctic circle, was found both at Cape Adare and Possession island by one of the party, C. E. Borchgrevink, while upon this expedition. Part of the lands supposed by previous explorers to constitute islands, were found to be joined to the main land of the antarctic continent; and land supposed to be islands by the earliest explorers, were found to be surrounded by water. Seven islands were discovered by Captain Larsen in 65° 7′ S., 58° 22′ W., two of them covered with volcanoes.

The general result of all these explorations is that in the north polar regions the unknown has been pushed back to within 80° north latitude, while in the Greenland-Nova Zembla regions exploration has been carried within about 400 miles of the north pole. On the other hand, the south polar region, with the exception of a few patches here and there, is almost a complete blank within the antarctic circle. See *Edinburgh Review*, April, 1891, and *Scribner's Magazine*, January, 1893.

Po'lar Lights. See AURORA BOREALIS.

Polar'ity. This is a term difficult to define, except by examples and illustrations, such as the two poles of the earth, or ends of the axis on which it revolves, and also the north and south poles of a magnet. A globe or sphere not in motion presents the same aspect in every direction; but let it begin to rotate about some diameter, and at once it becomes a polar body. Looked at from one end, it appears to rotate from left to right like the hands of a clock or watch; looked at from the other, it appears to rotate in a counter direction, or from right to left facing. To any one in the northern hemisphere looking toward the equator, the sun and other heavenly bodies appear to move from left to right, but to people of the southern hemisphere, facing the equator, they appear to move in an opposite direction, or from right to left. Thus we see that such terms as up and down, right and left, can be defined only by applying them to the motion or position of some particular object; and the rotation of any object may be used to give us an idea of its polarity. Perhaps the most familiar example of polarity is the magnet. Its polarity is a force polarity, the ends or poles of one magnet having a selective action upon the ends or poles of the other. This particular action is, however, only one among many manifestations of magnetism; and the general tendency among scientists is to explain all magnetic phenomena as essentially *rotational*, the difference in the poles of the magnet being accounted for by the theory of revolving currents of electricity in planes perpendicular to the direction of the magnetic force.

Polariza'tion of Light. In the evidence which is ordinarily adduced for thinking that light consists in a wave-motion of the ether, nothing is said as to whether light vibrations are longitudinal, as is the case with sound, or transversal, as is the case with water waves. The phenomenon which answers this question decisively is the polarization of light.



TOURMALINE PLATES.

The facts are as follows: If we take a thin slice of a tourmaline crystal, cut parallel to its crystallographic axis, and examine the light which passes through it from any ordinary source of illumination, say the sky, we shall find the transmitted light of a greenish, olive color. If now we take a second crystal, exactly like the preceding, and place it upon top of the first crystal, in such a way that the axes of the two pieces are parallel, we shall find the light transmitted as before, only with greater absorption, since it has now to pass through a greater thickness. Suppose, however, that we rotate one crystal upon the other, so that their axes are no longer parallel although their faces remain in contact, we shall find that the second crystal becomes less and less able to transmit the light delivered to it by the first crystal; and when the second crystal has been turned so as to have its axis at right angles to the axis of the first crystal, *no light at all will pass through both crystals*. This latter position is shown in B, Fig. 1; the former position, with axes parallel, is shown at A, Fig. 1. The ray of light is here to be imagined as falling upon the plate of tourmaline in a direction which is perpendicular to the plane of the drawing. Either crystal alone will transmit the original ray however the crystal be placed; but either crystal alone behaves very differently toward a ray which has once passed through a piece of tourmaline. In fact, the passage of the ray through the tourmaline has given it a new property; for it now behaves differently in different azimuths. Such a ray is said to be *polarized*. And the fact that it has different properties on different sides, so to speak, proves that light waves must be transversal. If the disturbance in the ether were "end on," as in the case of sound, it could not possibly make any difference how one rotated the tourmaline through which the light is viewed.

In the early part of the 19th century, it was discovered by Malus that light which has been reflected from any polished surface has this property, which is called polarization, in a greater or less degree; and when reflection

occurs at a definite angle, known as the "angle of polarization," the reflected beam is almost completely polarized. It has been proved by Hertz and Trouton that the vibrations in polarized light are at right angles to the plane of polarization.

Pol'der, in the Netherlands, is land below the level of the sea or the nearest river, which, originally a morass or lake, has been drained and brought under cultivation. An embankment forming a canal high enough to carry the water to the sea or river is made, and apparatus for lifting the water is placed at one or more points. If the lake deepens toward the center, several canals become necessary, formed at different levels as the water surface becomes lessened, a connection being maintained with each other and with the first or outer canal which carries the water to the sea or river. In the Schermer polder, in North Holland, are four canal levels, the land between them forming long parallelograms.

Pole'cat, a carnivorous animal with a long slim body like a weasel. There are four species inhabiting the Northern hemisphere. The common polecat of Europe is dark brown above and black below. Its fur is of little value. They sleep by day, and at night plunder poultry yards and dove-cotes. They feed also on rabbits, rats, mice, and birds. Very similar species are found in Siberia, Thibet, and North America. These animals emit a foul odor when disturbed. The ferret is a domesticated variety of polecat. In the United States, the name is sometimes incorrectly applied to the skunk.

Poles (Greek *polos*, a "turning point"), in geography, are the two extremities of the axis round which the earth revolves, the North Pole being situated 90° north of the equator, and the South Pole 90° south of it. In astronomy, the poles, which for distinction are called "celestial poles," are those points in the heavens to which the earth's axis is directed and round which the heavens seem to revolve. Unfortunately no stars mark the exact position of the celestial poles, and therefore the polestar is used for this purpose, its exact position being determined by noting the point between its upper and lower *culminations*. The term "poles" has also a wider application as denoting the extremities of a line passing through the center of a great circle perpendicular to its plane. Thus we have the poles of the horizon (which are the zenith and the nadir), the poles of the ecliptic, and the poles of a meridian, and in the same sense the terrestrial and celestial poles are spoken of as the poles of the equator and the equinoctial, respectively.

Poles, in physics, denote those points of a body at which its attractive or repulsive force is concentrated.

Pole'star or **Pola'ris,** the star nearest to the North Pole of the celestial equator. The star which at the present time goes under the name of the "polestar" is the star Alpha in the constellation of Ursa Minor. This star is, however, a little more than 1° from the North Pole and has a sensible motion around it. This star will in course of time (about 2,100 A. D.), come within 28′ of the North Pole of the heavens, and will then recede from it. Two thousand years ago the star Beta of Ursa Minor was the polestar, and about 2,300 years before the Christian era the star Alpha in the constellation of the dragon was not more than 10′ from the North Pole, while 12,000 years after the present time the bright star Vega in Lyra will be within 5° of it.

Police (*pō-lēce'*) are an organized force—especially in towns and cities—for the preservation of peace and order, and the prevention of crime. This definition applies more particularly to the police of the United States and of England, as the police of most European countries have much wider functions, and are often used by rulers and ministers for political purposes, and in a more or less oppressive manner. The existing system of police administration in England is of recent origin, and many features of it were introduced during the reign of the late Queen Victoria. In the early periods of English history, there was no such thing as a separate body of police, the responsibility for the maintenance of the peace being imposed on each hundred or tithing, and the individuals composing these divisions being held jointly liable for the consequences of any violations of law which occurred within their limits. In the larger towns, the inhabitants of the various wards kept watch within their limits, special watchmen being gradually introduced; but these duties of watch and ward were performed very inefficiently, and crimes were committed with marked impunity, especially in London and other large cities. During the 18th century, various efforts were made to remedy this state of things in London, and to secure a more efficient administration both in the prevention and detection of crime; but the results obtained were very unsatisfactory. At last, in 1829, Sir Robert Peel organized the Metropolitan police, placing the new force under the control of the secretary of state, and since that time the police of counties and boroughs have been organized upon the same principles as the Metropolitan police, except that they are under the local authority. The strength of this body of Metropolitan police is 15,694, comprising 31 superintendents, 578 inspectors, 1,930 sergeants, and 13,155 constables. The city of London police force numbers 1,002 men, exclusive of those on private service and detective duty. The police force throughout the kingdom is a civil, not a military body, with the exception of the Royal Irish constabulary, which is more military than civil. This force is directly under the Irish government, and its members are armed

and drilled as soldiers. It consists of over 12,000 members under the command of an inspector-general, each county being supervised by a county inspector, and also divided into separate districts over which district inspectors are placed. Below these officers are sergeants and constables, trained in the use of arms and disciplined as soldiers.

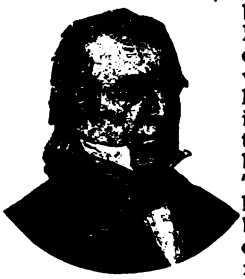
In the United States, each town and city has its separate administration; but, in general, the police system is very much like that of England. The present police organization of New York, which was substituted for the inefficient "night watch" in 1845, may be taken as a type of the American system generally. It consists of a board of police, comprising four commissioners appointed by the mayor, and the police force, who, with their various officers, are appointed by the board. The city is divided into four inspection districts, which are subdivided into thirty-five precincts. At the head of the force is a superintendent, under whom are four inspectors, a captain over each precinct, sergeants, roundsmen (visiting officers), patrolmen (the body of the force), and doormen at the stations. The captains report every morning to the central office. The roundsmen must see that the patrolmen perform their duties, and the sergeants are responsible for both roundsmen and patrolmen. Besides the general force there are several bodies, or "squads," organized for special services. Among these are the sanitary police, the detective force, the harbor police, park police, etc. In the year 1901, the police force of Greater New York numbered 7,444 men, of whom 6,261 were patrolmen, the annual cost of the entire force being $11,938,343. The police force of Chicago — now the second city in the Union — during the same year numbered 3,267, and cost $3,300,432; that of Philadelphia numbered 2,770, and cost $2,725,383; that of St. Louis numbered 1,300, and cost $1,386,500; that of Boston numbered 1,159, and cost $1,500,000; that of Baltimore numbered 880, and cost $900,000; that of San Francisco numbered 589, and cost $840,853.

Polit'ical Econ'omy has various definitions; but there is a general agreement that it is the science relating to the production, distribution, and exchange of wealth. The word is derived from the Greek words *oikos*, "house," and *nomos*, "law or rule"; but in its wider application it refers not only to the laws and institutions of nations in reference to industry and trade, but also to the arrangements of Providence in reference to the supply of man's physical wants. Although economic questions of various kinds occupied the minds of the Greeks and some other ancient nations, and were discussed by their leading thinkers and writers, there was no real science or system of political economy until the time of Adam Smith and his forerunners in the 18th century. Smith's *Wealth of Nations* was the first systematic exposition of the subject by a man thoroughly qualified for his task; and his teaching was defined by himself as a system of natural liberty. He opposed all regulations and restrictions of trade, such as protective tariffs that seem to interfere with the natural order of things, thus following the school of Rousseau, in advocating a return to nature from what he deemed a perverted civilization. He also followed the example of his predecessors, and showed himself in harmony with the new era by making labor the source of wealth. The greatness of Smith's work lies in the fact that he summed up the best thought of preceding times, and that his writings have been made the basis of all subsequent progress in economic science. But great as his influence has been, his ideas have by no means commanded universal or even general acceptance. His system has been variously criticised as being too abstract and merely theoretical; and his followers have been characterized as "students of maxims rather than the markets." The strongest point, perhaps, that is urged against him and his school is that they overlook the importance of the *nation* as the unit in economic growth and development. In answer to Smith's various arguments, it is urged that economic questions must be studied in the light of actual conditions in each state or nation, and that the wise policy can be determined only from a knowledge of all the factors that enter into industry and trade. Great changes have also taken place since Adam Smith's time, which have added new complications to the questions at issue, and have placed the science of political economy in a still more unsettled and unsatisfactory condition. Among these changes the most important is the introduction of machinery, by which individual enterprises have given place to vast corporations and "trusts," thus making the relations between capital and labor one of the leading questions in political economy; and it is urged with great force that the concentrations of capital make such a condition in the industrial world that the various issues between capital and labor cannot be settled by the mere "law of supply and demand," but that moral principles must also be invoked. Hence the relation of political economy to ethics must be considered by students of the science in our time.

In the United States, one of the leading questions in political economy is that of high or low tariff. While individual opinions range from the extreme positions of absolute free trade (that is, the admission of all foreign imports without duty) to tariff rates that would almost prohibit the introduction of foreign products, the two great political parties, Republican and Democratic, may be said to be divided on the question whether tariff duties should be levied on foreign imports for purposes of revenue only, or whether we should also have a "system of protection" under which our

manufactures should be secured against competition with those of England and other countries. This tariff question has been a fruitful theme of discussion by our statesmen and legislators from Washington's administration down to the present time, even to the extent of being made the "leading issue" in several presidential campaigns. See *Wealth of Nations*, by Adam Smith; *Principles of Political Economy*, by J. S. Mill; Clark's *Distribution of Wealth*, and Hobson's *The Economic of Distribution*.

Polk (*pōk*), **James K.**, eleventh President of the United States, was born in Mecklenburg county, N. C., Nov. 2, 1795. He was educated at the University of North Carolina, and after studying law was admitted to the bar at Columbia, Tenn., in 1820. Three years after this, he was chosen a member of the legislature of Tennessee, and in 1825 was elected to congress as the candidate of the Democratic party. In 1835, he was made speaker of the house of representatives, which position he filled with credit and ability. In 1844, he was the Democratic candidate for President against Henry Clay, and was elected by a popular majority of only 38,000, but by an electoral vote of 175 to 105.



JAMES K. POLK.

The principal feature of Polk's administration, which extended from March 4, 1845, to March 4, 1849, was the Mexican war, by which the United States acquired the great states of Texas and California and the territory of New Mexico. Texas was annexed by congress just before Polk's inauguration; and soon after he became President he sent General Taylor with a small force to occupy the disputed territory between the Neuces and Rio Grande rivers, Mexico claiming that this territory never belonged to Texas. In March, 1846, Taylor advanced to the Rio Grande and built Fort Brown, opposite the Mexican port of Matamoras. General Arista, the Mexican commander, then crossed the Rio Grande to attack Taylor, but was defeated at the two battles, Palo Alto and Resaca de la Palma, and forced to recross the river. War was at once declared by congress against Mexico and was prosecuted with energy and vigor until the City of Mexico was occupied by General Scott in September, 1847. During Polk's administration, by a compromise treaty with England, the northern boundary line of Oregon territory — now the state of Washington — was fixed at 49° north latitude. The low tariff act of 1846 was a favorite measure of Polk's, being passed in the senate by the casting vote of Vice-president Dallas. Other features of his administration were the admission of Wisconsin into the Union as a state in 1848; the adoption of the sub-treasury system by which the funds of the government are kept in vaults in Washington instead of being deposited in banks, and the creation of the interior department, its secretary being added to the cabinet of the President. On the expiration of Polk's term, he retired to his home at Nashville, Tenn., where he died a few months afterward, June 15, 1849.

Polk, Leon'idas, general in the Confederate army, and bishop of the Protestant Episcopal church, was born at Raleigh, N. C., April 10, 1806. He graduated at West Point in 1827, and received a commission in the artillery, but resigned and studied for the ministry. In 1838, he was consecrated bishop of Arkansas and Indian Territory, with charge of the dioceses of Alabama, Mississippi, and Louisiana; but in 1841 he resigned all these except the bishopric of Louisiana, which he held until his death, even when commanding a corps in the Confederate army. Soon after the outbreak of the Civil war, Bishop Polk tendered his services to the Confederate government, and was appointed major-general by Jefferson Davis. He commanded an army corps at the battle of Shiloh, and in October following was made lieutenant-general. At the battle of Chickamauga he commanded the right wing of Bragg's army, and being charged by that officer with disobedience of orders, was relieved of his command for a short time, but was afterward restored, and served under Gen. Joseph E. Johnston in Sherman's Atlanta campaign. He was killed by a cannon-shot while reconnoitering on Pine mountain, June 14, 1864.

Poll Tax, a tax levied by the *poll*, or head. In England, the imposition of a graduated poll tax in the time of Richard II. led to Wat Tyler's rebellion in 1381. A similar tax was imposed in 1513, and a tax, varying from 12*d* for a private person to £100 for a duke, was assessed in 1678 and abolished in 1689. In the United States, there is in some states a poll tax, varying from $1 to $3, while in others the imposition of such a tax is expressly forbidden by the state constitution.

Pol'len, the name by which the microspores of seed-plants are most commonly known. Pollen is developed within pollen-sacs, which occur on the anthers of stamens. Each pollen grain is an asexual spore, consisting of a single cell, which has an outer heavy and more or less modified wall, known as the "exine," and a delicate inner wall, known as the "intine." Pollen grains are often variously marked, sculptured, and even winged, by the modifications of the exine. Certain pollen grains, as those of the mallows, are covered with conspicuous spiny points, and this family may be recognized by its pollen.

Pollen has often been mistaken as the equivalent of a male cell, being spoken of as "the male element." It should be distinctly understood that pollen grains are microspores, and that microspores are asexual spores. When the pollen germinates, as other spores do, it produces a male gametophyte, as do all microspores. It is in connection with this new plantlet or male gametophyte that the sperms are developed. See POLLINATION.

Pollina'tion, the transfer of the pollen of plants from the stamen which produces it to the stigma which is prepared to receive it. Pollination is frequently confused with fertilization. Fertilization is the union of the male cell and egg, which may or may not follow pollination. In general this transfer of pollen is effected by one of two agents, the wind or insects. The plants which use wind as a carrier of pollen are called "anemophilous" plants; those which use insects for this purpose are called "entomophilous." The gymnosperms and many of the more primitive angiosperms, such as grasses and many of the common trees, are anemophilous. The great majority of angiosperms are entomophilous, and their flowers have been modified in every way to be adapted to insect visits, and the insects have been variously adapted to flowers. For anemophilous pollination, see GYMNOSPERMS. Entomophilous pollination is of two kinds; namely "self pollination," in which the pollen is transferred to the stigma of its own flower; and "cross pollination," in which the pollen is transferred to the stigma of some other flower. In the case of cross pollination the two flowers concerned may be upon the same plant, or upon different plants which may be quite distant from one another. The advantage of this relation to the insects is to secure food. This the flower provides either in the form of nectar or pollen, and the insects which pollinate flowers may be roughly divided into the two groups of nectar-feeding insects, represented by butterflies and moths, and the pollen-feeding insects, represented by bees, wasps, etc. The presence of these food supplies is made known to the insect by odor, form, and perhaps color of flowers. Those insects which are suitable for this work are necessarily flying forms, as creeping insects would brush off the pollen from their bodies in passing from one flower to another. Plants have many devices by which the unsuitable creeping insects, such as ants, may be warded off. Just what the advantage of cross pollination over self pollination may be is not very clear, but that it is of very great advantage is evident from the fact that the angiosperms have made most elaborate attempts to secure it. In most insect-pollinating flowers there are three problems: (1) to hinder self pollination; (2) to secure the visits of suitable insects; and (3) to ward off the visits of unsuitable insects. Most of the insect-pollinating flowers may fall into three great divisions on the basis of the methods they use to hinder self pollination. The first division includes those flowers in which the pollen and stigma are so related to each other in position that the pollen is not likely to fall upon the stigma. This method results in much of the irregularity of flowers, and conspicuous among these forms are the sweet peas, irises, and orchids. The story of cross pollination in orchids has been told by Darwin in a wonderfully interesting book. The second division includes those flowers in which self pollination is not prevented by the relative positions of the parts, but by the fact that the pollen and stigma are not ready at the same time. When the stigma is ready to receive, the pollen may not be ready for shedding; or when the pollen is ready for shedding, the stigma may not be ready to receive. These are the so-called dichogamous flowers (which see). It is evident that there may be two groups upon this basis; namely, those flowers in which the pollen is ready first, and those flowers in which the stigma is ready first. The former are called "protandrous flowers," the latter "protogynous flowers." The third division includes those flowers in which there are at least two forms, and the two forms are different from one another in the relative lengths of their stamens and styles, and also in the nature of their pollen. For example, in the common Houstonia, a small tubular flower, one kind of flower has the stamens included in the tube and the stigmas protruding; while the other kind has the stigmas included in the tube and the stamens protruding. Each kind of pollen is most effective upon the stigma of the same level. Accordingly, as an insect passes from one such flower to another, crowding its way into the tube, its thorax is likely to receive a band of pollen from the short stamens, and its abdomen another band from the long stamens. In this way the pollen from the thorax is rubbed upon the included stigmas and the pollen from the abdomen is rubbed upon the protruding stigmas. The whole story of the relation between insects and flowers is an exceedingly intricate one and full of surprises. JOHN M. COULTER.

Pollin'ium (in plants). In certain families, notably the milkweed and orchid families, all of the pollen grains formed within a pollen sac stick together in a mass, which is removed bodily by insects. These masses of sticky pollen are known as pollinia.

Po'lo, an equestrian game, which may be briefly described as hockey on horseback. An oblong space is marked out, the usual size of which is 300 by 200 yards; at each end in the center of the line two poles are fixed, 20 or 22 feet apart, forming the goals through which it is the object of the opposing sides to strike the ball. The players are mounted on ponies,

the size of which should not exceed 14 hands, and each player is armed with a polo stick, consisting of a strong cane about four feet long, with a crosshead about eight inches in length, with which to strike the ball of light wood. The proper number of players is four to a side, and in polo, as in most other games, combination is the first condition of success. The ponies need to be carefully trained, and they sometimes become very clever in understanding what is required of them. To become a good player requires a quick eye, good horsemanship, and a great deal of practice.

Po'lo, Marco, the greatest of mediæval travelers, was born at Venice about the year 1254. His father Nicolo Polo, and his uncle Maffeo Polo, about the time of his birth set out on a mercantile expedition, visiting Constantinople, the Crimea, and the court of Barka Khan at Sarai, and from thence proceeded to Persia and to the court of the great Kublai Khan at Cathay. Kublai heard their reports concerning the countries of Europe with great interest, and commissioned them as envoys to the pope. After an absence of nearly twenty years they reached Venice, in 1269, and two years later set out on another trip, taking young Marco with them, and arriving at the residence of Kublai Khan in the year 1275. Their second reception was even more cordial than the first, Kublai taking a decided fancy to young Marco, from the rapidity with which he learned the language and customs of the Mongols. The Polos did not return to Venice until the year 1295, when they were hardly recognized by any of their former friends and acquaintances, on account of their Tartar dress, and the imperfect manner in which they spoke their native tongue; but when their identity was fully established they were treated with great honor and distinction. In 1298, Marco was in command of a galley in the battle of Curzola, and was taken a prisoner to Genoa, where he was kept in confinement for a year or more. Here he dictated to another prisoner an account of his journey to the east; but his stories were very incredulously received by the people of his time. After his liberation he returned to Venice, where he died in 1324, and was buried in the Church of St. Lorenzo. See his work, edited by Col. Sir Henry Yule.

Polybius (*po-lib'i-us*), the Greek historian, was born about the year 204 B. C. at Megalopolis in Arcadia. He was one of the 1,000 Achæans who, after the conquest of Macedonia, in 168 B. C., were sent to Rome on the ground that the Achæans had failed to assist the Romans against Perseus. At Rome, he was the guest of Æmilius Paulus, and became the close friend of his son Scipio Æmilianus, accompanying him in his military expeditions. In 151 B. C., the surviving Achæan exiles were permitted to return to Greece; but Polybius followed Scipio in his African campaign, and was present at the destruction of Carthage in 146 B. C. But the war between the Romans and Achæans afterward summoned him to Greece, where he arrived soon after the taking of Corinth; and so grateful were his people for his services in securing favorable terms from their conquerors that they erected statues in his honor in his native city and elsewhere. It was about this time that he undertook the writing of his great historical work, the design of which is to show how and why all the civilized countries of the world fell under the dominion of Rome. He died about 125 B. C.

Polycarp (*pol'i-karp*), one of the early Christian fathers, was born about the year 69 A. D., and probably of Christian parents. Polycarp's life is a very important one, from the fact that he bridges the period between the age of the original apostles and that of his own disciple Irenæus. Whether he was actually appointed bishop at Smyrna by the Apostle John may well be doubted, but he certainly occupied a prominent position in the church from his earliest manhood. This is the tribute that Irenæus pays to his memory: "I can tell the very place where the blessed Polycarp used to sit and discourse. . . . Whatsoever things he had heard from John and others about the Lord he would relate as having received them from eyewitnesses."

Toward the close of his life, Polycarp visited Rome, and on his return to Smyrna became the victim of a persecution of the Christians in that place. Being offered his life by the proconsul if he would renounce Christ, he answered: "Eighty and six years have I served Him, and He has done me only good—why should I deny Him now?" The games being over, death by fire was substituted for death by wild beasts, the mob eagerly gathering fuel for the flames (A. D. 155.) The only writing left by Polycarp is an epistle to the Philippians, the authenticity of which has been seriously questioned, but may now be considered as clearly established.

Polycrates (*po-lik'ra-tēz*), tyrant of Samos from 536 to 522 B. C. After conquering several islands of the archipelago and even some towns on the Asiatic mainland, he waged a successful war against the inhabitants of Miletus, and defeated their allies, the Thesbians, in a great sea fight. His alliance with Amasis, king of Egypt, proves the importance of this island prince in the eyes even of great monarchs. According to Herodotus, Amasis so dreaded the misfortunes that the envious gods must be preparing for so fortunate a mortal, that he wrote a letter to Polycrates, advising him to give up his most valuable possessions. In compliance with this advice, Polycrates cast a signet ring of beautiful workmanship into the sea, but the next day a fisherman presented his prince with a large fish he had just

caught, and in its belly was found the ring that had been thrown away. From this Amasis concluded that Polycrates was a doomed man, and he immediately broke off the alliance. It is thought by some, however, that Polycrates himself broke off the alliance in order to secure the friendship of the Persian monarch Cambyses. At any rate, when Cambyses invaded Egypt, in the year 525 B. C., Polycrates sent him forty ships in which he placed all the Samians who were hostile to his government, hoping that they would never return. But they soon mutinied against the Persian authority, and sailed back to Samos for the purpose of overthrowing Polycrates. Failing in this effort, they proceeded to Sparta, and formed an alliance with both the Spartans and the Corinthians. A triple force of Samians, Spartans, and Corinthians now besieged Samos in vain, and Polycrates became more firmly established in his authority than ever. But evil fortune overtook him at last. His deadly enemy, Orœtes, satrap of Sardis, enticed him to visit Magnesia, where he was seized and crucified.

Polyembryony (*pŏlĭ-ĕm'brĭ-o-nĭ*) (in plants), a name applied to any case in which more than one embryo occurs in a seed. This is a thing of rare occurrence, although quite a number of embryos start in the seeds of Gymnosperms. As a rule, when several embryos begin, one of them sooner or later develops at the expense of the others, which gradually disappear. Now and then, however, more than one embryo is found in both Gymnosperms and Angiosperms, the extra embryo having arisen either from an extra fertilized egg, as is probably true in the Gymnosperms, or as the budding outgrowth from some part outside of the egg, as is often the case in orange seeds.

Polynesia (*pol-i-nē'shē-ă*), (Greek *polys*, "many"; and *nesos*, "an island"), a term applied to the islands of the Pacific ocean east of the Philippines, New Guinea, and Australia, except Japan, the Kuriles, Aleutians, Queen Charlotte, Vancouver, Revillagigedo, and Galapagos, which are geographical dependencies of the adjoining Asiatic and American continents. These Polynesian islands—also called "South Sea" islands—are distributed over a vast area of the sea, nearly 11,000,000 square miles, but the extent of dry land in this extensive area is less than 200,000 square miles; while the total population is probably less than 1,500,000. Polynesia comprises the three broad divisions of Micronesia, Melanesia, and East Polynesia, and each of these is again subdivided into several secondary groups. Micronesia lies on the extreme northwest, almost entirely north of the equator, and consists almost exclusively of small volcanoes and atolls, forming the five archipelagoes of Pelew, the Marianas, the Carolines, Marshall, and Gilbert. The area of all the islands in this division is only a little over 1,000 square miles; the population is estimated at about 100,000. Melanesia lies in the extreme west, south of the equator, and consists mainly of coral and volcanic islands, disposed in parallel lines from northwest to southeast, forming the eleven archipelagoes of the Admiralty, Bismarck, D'Entrecasteaux, Louisiade, Solomon, Santa Cruz, Banks, New Hebrides, New Caledonia, Loyalty, and Fiji, all inhabited by the Melanesian or dark-brown, oceanic race. The land area of this division is estimated at about 65,000 square miles, and the population at about 410,000. East Polynesia, the third and largest division, lies on both sides of the equator, and consists of the twelve archipelagoes of Hawaii (Sandwich islands), now belonging to the United States, Phœnix, Ellice, Tokelau, Samoa, Tonga, Kermadec, Austral, Cook (Herney), Tahiti (Society), Tua-motu (Low), Marquesas, New Zealand, besides numerous islets, such as Norfolk, Chatham, Easter, and many others. This division is the special domain of the large brown race, commonly called Polynesians, in a special sense. Although the Polynesian islands are spread over so large an area, there is great uniformity of climate among them, except in New Zealand. The mean temperature is about 70°, both in Hawaii and New Caledonia (about the two tropics), with an extreme range from 50° to 90°. For more than a century the oceanic peoples have been in contact with Europeans and Americans, and many of the Polynesians, as well as many of the Melanesians, profess some form of Christianity, the first mission being that to Tahiti in 1797 by the London missionary society. But this contact appears to have caused a remarkable decrease of the native population. For instance, the population of the Hawaiian islands has fallen from 300,000 at the time of Cook's first voyage, in 1797, to 154,000 at the present time, and a similar falling off has occurred in other islands. Everywhere the pure Polynesian race seems to be disappearing, which is a result due in part to the introduction of alcoholic drinks, in part to the changes of habits, dress, etc., introduced by the missionaries, but mainly to the ravages of the various diseases to which the people are subject. See *An Account of the Polynesian Race*, etc., by Fornander.

Polyp (*pŏl'ĭp*), the individual feeding animal in a colony of hydroids. The body is tubular, surmounted by a disc which is surrounded by tentacles. The disc is also perforated in the center by a mouth. The fresh-water hydra is an example of a single polyp. The name also applies to individual coral animals. See HYDRA, and HYDROZOA.

Polypetalous (*pŏlĭ-pĕt'al-ŭs*) **Flowers**, those in which the individual petals are separate and distinct. The contrasting term is "sympetalous" (which see). Polypetalous flowers are thought to be more primitive than

those which are sympetalous. Common illustrations are the buttercups, roses, etc.

Polyphemus (*pol-i-fē'mus*), in classical mythology, the son of Poseidon and the nymph Thoosa. He was a shepherd of immense size, and had only one eye in the center of his forehead. When Ulysses landed on the island of Sicily, he and his companions were seized by Polyphemus and confined in a cave. After the huge cannibal had eaten six of his twelve companions, Ulysses got him intoxicated and put out his eye with a burning pole, thereby escaping from the cave.

Polytechnic (*pŏl-i-tĕk'nik*) **School,** (Greek *polys*, "many"; *techne*, "art"), an institution in which the practical sciences, such as engineering, architecture, etc., are taught. The first school of the kind was established at Paris in the year 1794, under the name of School of Public Works. The Polytechnic School, as it is now called, is the school in which France trains her artillery officers and engineers, her directors of roads and bridges, her telegraph officers, and, in fact, all her officials who need to know something of the higher branches of technical science. In America, the oldest institutions of the kind are the Rensselaer Polytechnic Institute at Troy, N. Y., and the Franklin Institute at Philadelphia, both founded in 1824.

Pombal (*pom-bäl'*), **Sebastian Joseph, de Carvalho e Mello,** Marquis of, the greatest of Portuguese statesmen, was born May 13, 1699, at the castle of Soure, near Coimbra. In 1739, he was appointed ambassador to London, and six years later was sent to Vienna in a similar capacity. Just before Joseph I. ascended the throne, Pombal was made secretary for foreign affairs, and after the great earthquake at Lisbon, in 1755, he displayed such wisdom and ability that in the next year the king appointed him prime minister. After subduing a revolt instigated by the great nobles and the Jesuits, he abolished slavery in Portugal, sought to establish good elementary schools, and published a new code of laws. In addition to this, he reorganized the army and established a Portuguese East India company. The tyranny of the Inquisition was also broken, besides numerous other reforms. On the accession of Maria I. (in 1777) who was under clerical influence, Pombal was deprived of office and banished from court, while many of his institutions were abolished. He died at his castle of Pombal, May 8, 1782. The peasantry of Portugal always speak of him as "The great Marquis."

Pome (*pōm*), a fruit, such as the apple, pear, quince, in which the fleshy part is developed by a flower structure outside of the pistils. This structure is commonly referred to as the calyx, but it is really the cup-like outgrowth from which the sepals, petals, and stamens all arise. See FRUIT.

Pomegran'ate, the fruit of *Punica granatum*, a tree belonging to the loosestrife family. It is a native of Asia, and is very commonly cultivated throughout the tropics and semi-tropics. It is a tree which rises to a height of 15 or 20 feet, and has numerous slender branches, some of which are armed with thorns. The fruit is globular, about as large as a small apple, but with a leathery rind, of a deep golden color tinged with red, and contains very numerous seeds coated with a juicy edible pulp.

POMEGRANATE.

Pomerania (*pŏm'e-rā'ni-a*), a province of Prussia, bounded on the north by the Baltic sea, on the east by west Prussia, on the south by Brandenburg, and on the west by Mecklenburg. It is one of the lowest regions in Germany, and contains but few hills of even moderate height, but numerous lakes and ponds. The river Oder divides Hither Pomerania (next Mecklenburg) from Farther Pomerania, the shore of the latter being lined with sand dunes. The larger portion of Pomerania is under tillage, the agricultural products being varied and numerous. Today, its area is 11,628 square miles, with a population of 1,634,659. Pomerania formed part of the territory of the ancient Vandals, and when they moved south in the 5th century, it was occupied by Slavic tribes, one of whom was called Pomerani — hence the name of the region. The native princes assumed the title of duke in 1170, and joined the German empire. The duchy was overrun by the imperialists in the "Thirty Years' war," and they were followed by the Swedes, who established themselves in Hither Pomerania and in some towns of Farther Pomerania, and it was not until 1815 that the last Swedish possession was surrendered to Prussia. The capital is Stettin, population 210,680.

Pomona (*pō-mō'nä*), the Roman goddess of fruits and flowers. She was greatly beloved by a number of the rustic divinities, among whom were Sylvanus, Picus, and Vertumnus. Propertius tells us that the last named, after vainly trying to approach her under various forms, at last succeeded by assuming the guise of an old woman; and having awakened her feelings of pity, suddenly transformed himself into a blooming youth. In works of art, Pomona is generally represented with fruits in her lap or in a basket, and with a

garland of fruits in her hair and a pruning knife in her right hand.

Pompadour (*pŏn-pä-dōr'*), **Jeanne Antoinette Poisson,** Marquise de, the most famous among the mistresses of Louis XV., was born at Paris, Dec. 29, 1721. She possessed remarkable grace and beauty, and charmed every one with her wit and vivacity. In 1741, she married Le Normant d'Etioles, and soon became a queen of fashion in Paris. But this did not satisfy her, as her heart was set on becoming the king's favorite. At length she attracted the attention of the king at a ball, and ere long she was established at Versailles with the title of Marquise de Pompadour. For twenty years she was almost the absolute ruler of France, the king being merely a spectator of his reign without even taking interest in it. She filled all public offices with her favorites, and made her own creatures ministers of France. Although her policy was disastrous and her wars unfortunate, she retained her position to the end by relieving the king of all business, by diverting him with private theatricals, and even by consenting to his vices and immoralities. At last her nerves gave way under the strain and excitement to which she was subject, and after an illness of twenty days she died April 15, 1764. Her breath fled on the wings of a playful sally, "Stay, Monsieur Curé," she said to the priest, who was leaving her room, "we shall go out together."

Pompeii (*pom-pā'yē*), an ancient Roman city, near the mouth of the Sarnus river and at the foot of Mt. Vesuvius, 13 miles southeast of Naples. It was founded by the Oscans about 600 B. C., and was afterward occupied by the Etruscans and Samnites, the latter being dispossessed by the Romans about 100 B. C. From that time until its destruction in 79 A. D., it was a sort of summer resort, frequented by the Roman aristocracy. In the year 63 A. D., its magnificent buildings were nearly all leveled to the ground by an earthquake, and some years elapsed before the citizens could be induced to return and rebuild them. Before this work was fully completed, in the year 79 A. D., the neighboring mountain of Vesuvius, whose volcanic fires had been slumbering for unknown ages, burst forth in a violent eruption, which buried the cities of Pompeii and Herculaneum under dense beds of cinders and ashes. Amid the deep gloom that covered land and sea the panic of the citizens was aggravated by repeated shocks of earthquake, and for three days the flight continued till Pompeii was abandoned by all who could effect their escape. By the fourth day the sun again became dimly visible, and the more courageous of the citizens began to return for such portions of their property as they could rescue from the ruins. The desolation and distress were so great that the Emperor Titus organized relief on a grand scale, and even undertook to clear and rebuild the city. This attempt, however, was soon abandoned; and the unfortunate city remained a heap of hardened earth and ashes until its very site was forgotten, and even the celebrated topographer Cluverius was unable to fix it with certainty. This difficulty arose in large measure from the fact that the convulsions attending the eruption had turned the Sarnus from its regular course, and so raised the sea beach that the ruins of the city were nearly a mile from the coast. It was not until the year 1748 that an accidental discovery revealed the fact that beneath the vineyards and mulberry grounds which covered the site, there lay the ruins of a city far more accessible, if not more interesting, than those of the previously discovered Herculaneum. The labor of excavation proceeded fitfully until the year 1860, when the Italian government commenced the work of unearthing the city in a systematic and scientific manner.

The general plan of the town is very regular, the streets being straight and crossing each other at right angles, or nearly so. The streets rarely exceed 20 feet in width, the broadest yet found being less than 30 feet, while the back street running parallel to the main lines are only about 15 feet. They are usually paved with blocks of lava fitted very closely together, and the marks of horses' hoofs and the ruts of chariot wheels are still plainly visible. The houses at Pompeii are generally low, rarely exceeding two stories in height. Not more than 300 skeletons have thus far been discovered in the ruins of Pompeii, chiefly in cellars and underground apartments, which fact makes it probable that most of the inhabitants escaped. According to Dion Cassius, a large number of people were assembled at the theatre when the catastrophe occurred; but as no bodies have been found there, they either fled from the city in time to avoid destruction, or their bodies were taken out and buried elsewhere. The population of the city has been estimated as low as 12,000, and as high as 50,000; but the more recent opinions of investigators incline to the lower number. See E. Neville Rolfe's *Pompeii, Past and Present.*

Pom'pey the Great was born in the year 106 B. C., and at the age of seventeen fought with his father in the Civil war between Marius and Sulla on the side of the latter. When Sulla returned from Greece to Italy to oppose Marius, Pompey hastened into Picenum, and there raised an army of three legions, with which he drove the soldiers of Marius out of the district, and then joined Sulla. Soon after this he was sent to destroy the remains of the Marian or democratic faction in Africa and Sicily; and on his return to Rome was granted a triumph and honored with the title of Magnus, "the great." His next exploits were driving the forces of Lepidus out of Italy and fighting the forces of the

brave Sertorius in Spain. Pompey suffered a number of defeats in this campaign, but was able to bring the conflict to a successful issue after the assassination of Sertorius. On his way back to Rome, he routed the remnant of the forces of Spartacus, and thereby closed the Servile war. For this service he was awarded a triumph, while Crassus, who had defeated the main body of the forces of Spartacus, received only an ovation. Pompey was now the idol of the people, and though legally ineligible to the consulship, he was chosen to that position, the senate removing his disabilities by a special act.

In the year 67–66B. C., Pompey again distinguished himself by clearing the Mediterranean sea of the pirates who had so long infested it; and during the next four years he conquered Mithridates, king of Pontus; Tigranes, king of Armenia, and Antiochus, king of Syria. On his return to Italy, he disbanded his army, and in the year 61 B. C. entered Rome in triumph for the third time. Pompey now sought to have his acts in Asia ratified by the senate and certain lands divided among his veterans; and on that body refusing to accede to his wishes, he, in connection with Crassus, formed the alliance with Julius Cæsar, known in history as the "First Triumvirate." For a time they carried everything before them, and the political alliance was made closer and stronger by the marriage of Pompey and Cæsar's daughter Julia. In the year after this, Cæsar led his army into Gaul, and there for nine years enjoyed a career of conquest and glory, while Pompey was idly wasting his time and energies at Rome. Jealousies arose between the two; and after the death of Julia, in the year 54 B. C., Pompey returned to the aristocratic party which desired to check Cæsar's progress, and, if possible, to strip him of his command. The senate ordered Cæsar to disband his army by a certain day, or be declared a public enemy; and he answered this demand by crossing the Rubicon with his soldiers and defying the senate and its army under Pompey. The civil war that ensued was ended with the battle of Pharsalia, in the year 48 B. C., in which Cæsar was completely victorious. Pompey fled to Egypt, and was treacherously murdered while landing from a boat. His head was cut off and presented to Cæsar on his arrival in Egypt. But Cæsar was too magnanimous to be pleased with such a sight, and caused the murderer of Pompey to be put to death.

Pom'pey's Pillar, a celebrated Corinthian column standing near Alexandria, in Egypt, on an eminence south of the walls. Its total height is 98 feet 9 inches, the height of the shaft being a little over 70 feet. The Greek inscription on the base shows that it was erected in 302 A. D., by Publius, prefect of Egypt, in honor of the Emperor Diocletian; and it is supposed to record the conquest of Alexandria by Diocletian in the year 296 A. D.

Ponce de Leon (*pŏn'thā dā lā-ōn'*), **Juan,** the discoverer of Florida, was born at San Servas, in Spain, in 1460; was a court page, served against the Moors, and in 1502 sailed with Ovando to Hispaniola, and became governor of the eastern part of the island. In 1510, he obtained the government of Porto Rico, and had conquered the whole island by 1512, when he was deprived of his post. He then, broken in health, set out in quest of the fountain of perpetual youth, and on the 27th of March, 1512, found Florida, landing a little to the north of where St. Augustine now stands. He secured the appointment of governor of the country, and attempted to conquer his new subjects, but failed and lost nearly all his followers. He died in Cuba, July, 1521.

Pon'cho, an important article of male attire in Chile, the Argentine Republic, and other parts of South America. It consists of a piece of woolen or alpaca cloth, six or seven feet long and three or four feet broad, with a slit of a foot or more in the middle through which the wearer passes his head, so that the poncho covers the shoulders and hangs down before and behind. Waterproof ponchos are worn by soldiers in the army to a great extent, especially by cavalrymen.

Pontiac (*pon'ti-ak*), chief of the Ottawa Indians, was born about the year 1712. In 1746, he defended Detroit, which was then a French settlement, against the attacks of certain hostile tribes, and he is also said to have led his warriors at Braddock's defeat in 1755. After the French had surrendered Canada, his hatred of the English prompted him to organize a combined attack upon all the English garrisons and settlements with a view to the extermination of what he called "those dogs dressed in red." The 7th of May, 1763, was selected as the day for the attack, which in most places was successful; but at Detroit, where Pontiac commanded in person, the commander was forewarned, and a five months' siege ensued. Pontiac resorted to every means familiar to savages to reduce the place, but was unsuccessful. Peace was finally made in 1766, Pontiac being forced to submit to British rule. He was killed at Cahokia, Ill., by a drunken Indian in the year 1769.

Pon'tifex, the title borne by the members of one of the great religious colleges among the ancient Romans, the other being the college of Augurs. Although it is customary to speak of the college of pontiffs as a "priesthood," it was not such, strictly speaking; that is, the members were not charged with the worship of any particular divinity, nor did they conduct sacrifices. The duties of the pontiffs embraced the regulation of all the religious rites and ceremonies of the state —how the gods should be worshiped, how

burials should be conducted, how the manes (departed spirits) of the dead should be appeased. In matters of religion, their authority was supreme; there was no appeal from their decisions; and they themselves were responsible neither to the senate nor to the people. Their president was termed pontifex maximus. Their number, including the pontifex maximus, was originally five, all of whom were taken from the patricians. In the year 300 B. C., the Ogulnian law raised the number to nine, four of whom were to be plebeians. The first plebeian, however, who attained the dignity of pontifex maximus was Tib. Coruncanius, in 254 B. C. Sulla, in 81 B. C., increased the number of pontiffs to 15, and Julius Cæsar to 16, he himself filling the position of pontifex maximus. During the empire, the emperors generally discharged the functions of the position, but after the establishment of Christianity the title was assumed by the bishops of Rome, and the term pontiff is now one of the designations of the pope.

Pontif'ical, one of the service books of the church of Rome, in which are contained the several services in which the bishop, or a priest delegated by the bishop, officiates. The pontifical now in use throughout the western world is the Roman pontifical, first printed in 1485, revised under Clement VIII., in 1596, and repeatedly republished since that time. It contains the services for ordinations, for religious processions, and receptions of monks and nuns, consecrations, benedictions, as well as of the solemn administration of those sacraments by a bishop which are ordinarily administered by priests. Besides the prayers to be recited, the pontifical also lays down the ceremonial to be observed.

Pontine (*pon'tēn*) **Marshes,** a low marshy district forming the southern part of the Campagna of Rome, and extending from Velletri southeast to the sea at Terracina. The length of the plain is about 28 miles, the breadth varying from 4 to 12 miles. The formation of these marshes is due to the fact that the streams flowing down the Volscian mountains cannot find their way to the Mediterranean on account of the accumulations of sand along the coast. The Appian way was projected through this district in the year 312 B. C., and various plans were tried by the ancient Romans for draining the marshes, but with poor success. Popes Boniface VIII., Martin V., and Sixtus V. made earnest efforts to redeem the tract from waste, but the results were far from satisfactory. By the expenditure of some $2,000,000, Pope Pius VI., during the years 1777–96, brought the Pontine marshes to their present state, in which a portion of the land is brought under cultivation, and other portions furnish pasture for horses, cattle, and other animals.

Pontoon' (Latin *pons*, "a bridge"), a number of boats connected together and stretched across a lake or stream of water so as to furnish a temporary bridge for the passage of an army. From the earliest times pontoon bridges have been used in crossing streams; and a pontoon train has become a necessity for every army manœuvering in a country where there are rivers too deep to be forded, many important campaigns having proved failures from lack of pontoons.

Pon'tus, the name given by the ancient Greeks to a country in the northeast of Asia Minor, bordering on the Pontus Euximus (whence its name), and extending from the river Halys in the west to the frontiers of Colchis and Armenia in the east. The name seems to have come into use after the era of Alexander the Great. Previous to that, Pontus was governed by a satrap of Persia. One of these satraps, Ariobarzanes by name, early in the 4th century B. C., laid the foundations of an independent sovereignty. He was succeeded by a line of princes mostly called Mithridates, the greatest of whom, Mithridates VI., proved one of the most formidable enemies that Rome ever encountered. After he was overthrown by Pompey, in the year 66 B. C., Pontus was annexed to Bithynia.

Poole, William Frederick, an American bibliographer and librarian, compiler of the *Index to Periodical Literature*, was born at Salem, Mass., Dec. 24, 1821, and graduated at Yale college in 1849. While at college he was librarian of a literary society, and prepared the first edition of his *Index*, subsequent editions appearing in 1853 and 1882. A supplement by Poole and W. J. Fletcher was issued in 1888. He was for many years librarian of the Chicago City library, and later was librarian of the great Newberry library in that city. He died at Chicago, March 1, 1894.

Poo'na or **Poo'nah,** a town in British India, situated on the Muta, 120 miles southeast of Bombay. Although the place abounds in beautiful gardens, the streets are mostly crooked and narrow, and the houses poor. The city was the capital of the Mahratta princes, but was occupied and annexed by the British in the year 1817. Here have been built the Decca college and the college of science, a normal school, a high school, and other educational establishments. Population with suburbs 171,000.

Poor Laws. The obligation of providing for the poor has been recognized by all civilized nations. Among the primitive peoples of the earth, the giving of alms to those who were in need was inculcated as a religious observance, and the ancient European nations regarded a provision for the poor as a matter of state policy. In early times, Athens could boast of having no citizen in want, "nor did any disgrace the nation by begging." But war at length brought poverty in its train, and the state decreed the maintenance of those

who were wounded in battle, and afterward of the widows and children of those who fell. There were also societies for the relief of distress among some of the Grecian states. Among the Romans the distribution of grain was introduced by Caius Gracchus, and continued till the fall of the empire. In the time of Augustus, 200,000 people were thus fed. Cicero mentions this provision of the Roman law as one in high favor with the people, since it furnished them abundant subsistence without labor; other Roman writers describe its results as injurious, creating a nation of idlers and mendicants, and leaving the soil uncultivated.

In the middle ages, the great body of the laboring classes were in a condition of serfdom, and looked to their feudal lords for support. But the Church of Rome constituted herself the great receiver and dispenser of alms. The rich monasteries and abbeys distributed doles to the poor, as is still done at the mosque under the Mohammedan system. In most states of continental Europe, the church remains to a greater or lesser extent the source of relief to the poor, the state only stepping in when the contributions of the church and of private charity are insufficient. In England, the statute of 1388 is the first that makes provision for the impotent poor. Various statutes were passed after that time, culminating in the statute of 1601, which has formed the basis of the poor-law system of England up to the present time. It taxed every inhabitant of every parish for the relief of the poor, and directed the justices in every county to appoint three or four substantial householders in each parish to be overseers of the poor in connection with the churchwardens.

Various efforts were made to remedy abuses which arose under this system, of which the workhouse system was one of the earliest. All who refused to be lodged in the workhouse were refused relief. But the act of 1796 repealed the workhouse test and allowed relief to be given in aid of wages, so that the poor-laws were practically turned into a mode of paying wages. Various changes were made from time to time, and finally in 1871 the poor-law board was abolished and its powers were transferred to the local government board. The fundamental rule in England and Wales is that each parish is bound to maintain its own poor, and this is done by a poor-rate which churchwardens and overseers may levy on all persons occupying land in the parish. In 1899, the poor-rates raised for the year, under the Local Government act of 1894, amounted to over a hundred million dollars.

In the United States, a system of relief somewhat similar to that of England prevails in most of the states. "Poor-houses" are established by the county authorities, to which persons unable to support themselves are transferred and cared for, such work as they are able to do being provided for them. In some states, provision has been made for "children's homes," where all children under a certain age, whose parents are dead or unable to provide for them, are fed, clothed, and educated. Happily thus far the number of dependent persons in America is so small that the tax for their support is not seriously felt.

Poore, Benjamin Perley, an American journalist, was born at Newburyport, Mass., Nov. 2, 1820. He was apprenticed to a printer when a boy and grew up in a newspaper office. From 1838 to 1840 he edited the *Southern Whig* at Atlanta, Ga. He was sent with the embassy to Belgium in 1841, as an attaché, and remained in Europe seven years. While abroad he collected valuable data for the archives of the state of Massachusetts. In 1854, he was Washington correspondent of the Boston *Journal*, and served at the same time as clerk of the Senate committee for printing records. He became editor of the *Congressional Directory* in 1867. He published a number of works, among which those most largely sold were the *Life of Zachary Taylor* (1848), the *Conspiracy Trial for the Murder of Abraham Lincoln*, and *Sixty Years at the Federal Metropolis*. He died at Washington, D. C., May 30, 1887.

Pope, a title first given to all bishops of the Christian church, but now exclusively applied to the bishop of Rome, or head of the Catholic church. Tradition, confirmed by the faith of the church, represents St. Peter as the first bishop of Rome. Whether he were such or not, it was certainly natural that the early bishops residing in the imperial city should acquire a large measure of influence and importance, and that after the empire became Christian, they should attain some considerable degree of temporal power. The temporal power of the pope was not fully established, however, until the year 754, under Pepin, king of the Franks. From that time forward, the history of the papacy has been a contest, of greater or lesser intensity, with the princes and rulers of Europe, in which now one and now the other of the contending parties prevailed. At the present time, the pope is stripped of all temporal power, but his authority over the church in all matters spiritual and ecclesiastical is supreme and unquestioned, the Vatican council which assembled at Rome in the year 1870 having proclaimed his infallibility on all questions of faith and morals. Whenever a vacancy occurs in the papal chair, it is filled by the cardinals choosing one of their number to occupy the place. A history of the more important popes will be found under their several titles.

Pope, Alexander, English poet, was born at London, May 21, 1688, his father being a Roman Catholic and a man of considerable means. Although Pope's early education

was rather irregular and unsystematic, his father retiring from business and removing to Binfield, near Wokingham, soon after his birth, his application to study must have been very close, for even in his juvenile poems there are many traces of profound thought. In 1711, Pope published his *Essay on Criticism*, which placed him at once in the front rank of the literary men of his day; and in 1712 appeared the *Rape of the Lock*, which may be considered the most imaginative of all his poems. Soon after this appeared his translation of Homer's *Iliad*, which brought him a fortune of some $30,000. A translation of the *Odyssey* followed a few years later, and in 1728 he issued the third volume of *The Dunciad*. The *Essay on Man*, published in 1734, is a didactic poem, and although almost wholly deficient in the imaginative quality, is a masterpiece of wit and versification. Pope's command of terse and smooth expression is here seen at its highest; and it has been well said that this poem contains more familiar quotations than any other poem of equal length in the English language. Pope died at Twickenham, near London, May 30, 1744, leaving behind him a literary fame that has suffered no eclipse in a century and a half.

Pope, John, an American general, was born at Louisville, Ky., March 16, 1822, and graduated at West Point in 1842, after which he entered the engineer corps of the United States army. He served in the Florida war of 1842–44, and afterward in the Mexican war, winning the rank of captain for his conduct at the battles of Monterey and Buena Vista. At the outbreak of the Civil war, he was appointed brigadier-general of volunteers, and in the spring of 1862 highly distinguished himself by the capture of New Madrid, Mo., and "Island No. 10," in the Mississippi river. On account of these signal successes he was transferred to the east and placed in command of the forces formerly under Generals Fremont, McDowell, and Banks, each of whom had been outgeneraled and beaten by "Stonewall" Jackson. He conducted a very active and vigorous campaign against Lee and Jackson, but was defeated at the second battle of Bull Run, Aug. 29–30, 1862. He then requested to be relieved, and was transferred to the department of the northwest. Pope attributed his defeat to the failure of Gen. Fitz John Porter to attack Jackson's forces, as ordered on the 29th of August. Porter was court-martialed for this offense and dismissed from the army, but in 1886 he was restored. In the year 1882, Pope was made a major-general in the regular army, and retired on half-pay in 1886. He died while on a visit to the Soldiers' and Sailors' Home at Sandusky, O., Sept. 23, 1892, and was buried at St. Louis, Mo., three days later.

Pop'lar, a species of the genus *Populus*, which belongs to the willow family. The genus contains about twenty-five species, which are natives to the northern hemisphere, about half of them belonging to North America. The poplars may be divided in general into two groups, the balsam poplars with sticky buds, and white poplars or aspens with buds not sticky. The common balsam poplar is *P. balsamifera*, sometimes also called "tacaamhac." One of its varieties (*candicans*) is known as the "balm of Gilead." The common "cottonwood" or "Carolina poplar" is *P. moniliferа*. The black poplar of Europe (*P. nigra*) is familiar in this country through its variety *italica*, which is the Lombardy poplar, probably of Asiatic origin.

POPLAR LEAF AND CATKIN.

The common American aspen is *P. tremuloides;* the larger species being *P. grandidentata*, which is in cultivation in its "weeping" forms. A very commonly planted wild poplar is the "abele" of Europe, *P. alba*, which has leaves white cottony beneath. The name "poplar" or "white poplar" has also been wrongly applied to a tree in a very different group, namely, the great "tulip tree" (*Liriodendron*), which is closely related to the magnolias. It is this tulip tree which yields the so-called "poplar" lumber of commerce.

Pop'lin, a fabric of dry goods produced by weaving a weft of worsted yarn into a warp of silk. On account of worsted yarns being thicker than the silk, poplins always have a corded appearance. They may be either plain or figured, and are used for dress goods, and for fine upholstery. The manufacture of poplin goods is of French origin, and was introduced into England and Ireland by Protestant refugees during the 17th century.

Popocatapetl (*pō-pō-kä-tä-pet'l*), a volcano about 40 miles southeast of the City of Mexico. It rises in the form of a cone about 1,700 feet above the level of the sea. Although smoke still issues from the mountain, no eruption has taken place since 1540. It is frequently scaled, and in its crater, which is nearly a mile in diameter and about 1,000 feet deep, much sulphur is found.

Pop'py, species of the poppy family (*Papaveraceæ*), but in the narrowest sense the name belongs to the genus *Papaver*, to which the opium poppy (*P. somniferum*) of the Old World belongs. This poppy is largely cultivated in Europe and Asia for its capsule, from which the drug opium and the poppy oil are obtained. It is a native of the Mediter-

ranean region. Among the commonest native poppies are the "argemones" or "prickly poppies," which are found in cultivation, and also occur over vast areas in the west. The common "blood root" (*Sanguinaria Canadensis*) of the early spring is also a poppy, while the "yellow" or "celandine poppy" (*Stylophorum diphyllum*) is also a well-known poppy of the early spring. The Californian poppy, with its pale dissected leaves and long-stalked brilliantly colored flowers, is *Eschscholtzia Californica*. It occurs in California in great masses, often giving most brilliant and variegated colors to a landscape. This poppy is extensively cultivated.

OPIUM POPPY.

Por'celain. See POTTERY.

Por'cupine, an animal with sharp spines or quills among the hairs. The Old World porcupines are ground animals and live in burrows; those of the New World are mainly tree animals. They belong to the group of rodents or gnawing animals. The common Canada porcupine has a stout body, about forty inches long, with a short tail. The hair is dark brown, and the spines are from four to six inches long. They are almost hidden in the hair. These animals occur from Maine to Texas. The tree porcupine of tropical South America and Mexico is of slighter build, and has a tail capable of grasping.

PORCUPINE.

Poros'ity, a term by which we express the fact that no body of matter, whether solid or liquid, completely fills the space it occupies, as the particles or molecules of all bodies have spaces between them filled with air, which spaces are called *pores*. Many objects, such as wood and cloth, show their porosity by the readiness with which they absorb water or any other liquid. Under heavy pressure, water has been forced through iron, silver, and other metals; and the porosity of water itself has been proven by mixing it with alcohol and noting the fact that the bulk of the mixture is much less than the sum of the two bulks before the mixture.

Porphyry (*pôr'fi-ry*), the name applied to those igneous rocks which are made up of large and distinct crystals, imbedded in a matrix of small and often indistinct crystals. The term also is sometimes applied to lavas, the matrix of which is but partly crystalline. The name, therefore, refers to the structure of the rock, not to its composition. A granite would be called porphyritic if some of its crystals, for example some of its feldspar crystals, were conspicuously larger than others. A quartz porphyry is one in which the conspicuous crystals (phenocrysts) are all quartz. Light-colored igneous rocks are more commonly porphyritic than dark ones.

Porpoise (*pôr'pŭs*), a sea mammal belonging to the group of toothed whales. They are similar in general appearance to dolphins, but have a shorter snout. They are dark above and whitish below. Porpoises are common in the North Atlantic near shore, and often ascend rivers. They feed on such fish as mackerel and herring, for the capture of which their teeth are well adapted. The bay porpoise of the Pacific coast is the smallest of the whale family, being often not more than four or five feet long. Some other species of porpoises reach a length of about nine feet. Their very thick hide is beaten down and made into soft leather. Their fat yields an oil of fine quality.

PORPOISE.

Port Ar'thur, called by the Chinese "Lu-shun-k'ow," is a naval station on the north coast of China, in the province of Shing-king, about 275 miles east of Peking. Up to 1881 it was merely a harbor of refuge for coast-wise sailing vessels; but in that year China determined to make it a naval port for her northern squadron. It is entirely surrounded by hills; and at great expense it was fitted up with dry docks, foundries for the casting of heavy ordnance, and everything needful to constitute it an important station. It grew from a mere handful of mud huts in 1881, to a place of 6,000 inhabitants in 1893. In 1894, it was destroyed by the Japanese, as a result of the war provoked by China. In 1898, Russia obtained a lease of this harbor for twenty-five years, subject to renewal; and with it was obtained possession of the adjacent seas and all the Chinese territory to the north. This whole area is under the civil and military control of a governor appointed by Russia. Port Arthur, though small, is naturally impregnable; and its many fortifications are being made still more formidable by the Russian authorities. A certain part of the harbor is open to the commerce of all nations, but other parts are strictly reserved for Russian (and Chinese) men-of-war. The acquisition of Port Arthur by Russia led to

the occupation of Wei-Hai-Wei by Great Britain.

Port Dar'win, one of the finest harbors in Australia, is situated on the coast of the northern territory of South Australia, which is nearly 16 times the size of England. Its entrance is two miles wide, and vessels of any tonnage can sail in it with safety. Palmerston, the chief town on its shores, is the land terminus of the overland telegraph, and is the starting-point of a railway to the gold fields of the interior, 150 miles distant. A telegraph line is run overland from the north to the south of Central Australia, that is from Port Darwin to Adelaide, the capital, a distance of over 2,000 miles.

Port Eliz'abeth, a seaport of the British colony of the Cape of Good Hope, is situated on the western shore of Algoa bay, 85 miles by rail from Graham's town, and 350 miles from Kimberley. Its public buildings are the town house, the provincial hospital, churches, a college, a library, a museum, etc. The town was laid out in 1820, and in 1891 the population had grown to 23,266.

Port Hu'ron, a city of Michigan, is on the St. Clair river, where it issues from Lake Huron. The city has a fine custom-house, shipyards, and dry docks, sawmills, grain elevators, and a large commerce in timber brought down by the Black river. A railway tunnel, passing under the St. Clair river, connects the town with Sarnia, in Canada, and steamboats ply the river daily between Port Huron and Detroit. Population in 1900, 19,158.

Port Lou'is, the capital and principal port of the British colony of Mauritius in the Indian ocean, is situated on the northwest coast, and is inclosed by a circle of lofty hills. It is a coaling station of the British navy, and has barracks, harbor defenses, and military storehouses. Population with suburbs in 1899, 52,517.

Port Said (*sä'ēd*), an Egyptian seaport town on the west side of the Suez canal, on a strip of land between Lake Menzaleh and the Mediterranean. The place was named after Said Pasha, the promoter of the Suez canal, and depends wholly on the canal trade, being mainly a coaling station for steamers. Population 42,095.

Port'cullis, a strong timber or iron grating sliding up and down in the jambs of an entrance to a castle for the purpose of defending it from assailants. The lower ends of the vertical bars had spikes to stick in the ground, or to injure those on whom it might fall. A powerful mechanism of windlasses was required to work the portcullis.

Por'ter, David, an American naval officer, was born at Boston, Mass., Feb. 1, 1780. He was appointed a midshipman in the navy in 1798 and lieutenant in the year after. At the beginning of the War of 1812, he was made captain, and captured the first British ship taken in the war. In 1813, with his ship *Essex,* he nearly destroyed the English whale-fishery in the Pacific and took possession of the Marquesas islands; but in March, 1814, his frigate was destroyed by the British in Valparaiso harbor, and he returned home on parole. He afterward commanded an expedition against the pirates in the West Indian waters, and was court-martialed and suspended from duty for six months for compelling the authorities of Porto Rico to apologize for imprisoning some of his officers. In the year 1826, Porter resigned his commission in the United States navy and was placed for a time at the head of the Mexican navy. In 1829, he was appointed consul-general to the Barbary states and afterward minister to Turkey. While acting in the latter capacity he died at Constantinople, March 3, 1843.

Por'ter, David Dixon, an American admiral, son of the above, was born at Chester, Pa., June 8, 1813. He accompanied his father on his cruise against the pirates in 1825, and was for some time a midshipman in the Mexican service. He entered the United States navy in 1829, and after being employed on the coast survey from 1836 to 1841 he became lieutenant, and then served till 1845 on the Mediterranean and Brazil stations, afterward returning to the coast survey. At the commencement of the Civil war, he was appointed commander of the *Powhatan* and ordered to Pensacola; but afterward he was placed in command of the mortar flotilla, with which, under Farragut, he successfully bombarded the forts of New Orleans. In 1863, he was placed in command of the Mississippi gunboats and rendered such signal service in the siege of Vicksburg that he was raised to the rank of rear-admiral. Transferred to the North Atlantic squadron, in December of the next year, he bombarded and silenced Fort Fisher, and in January, 1865, the place was captured by the combined action of the military and naval forces. At the close of the war, Porter was made vice-admiral, and in 1870 succeeded Farragut as admiral of the navy. He died at Washington, D. C., Feb. 13, 1891.

ADMIRAL PORTER.

Por'ter, Fitz-John, an American general, was born at Portsmouth, N. H., Aug. 31, 1822, and graduated at West Point in 1845.

During the Mexican war he participated in the siege of Vera Cruz and in the battles of Cerro Gordo and Chapultepec, and was wounded in the assault upon the City of Mexico. In the summer of 1861, having been appointed brigadier-general of volunteers, he was placed in command of a division of the army of the Potomac by General McClellan; and at the opening of the Virginia peninsular campaign, in the spring of 1862, he superintended the siege of Yorktown. Soon after this, Porter was placed in command of the 5th army corps, and took an active part, distinguishing himself both for courage and military skill in the "Seven Days' battles," especially at Malvern Hill. After McClellan's retreat, his corps was ordered to re-enforce General Pope in his campaign against Lee and Jackson. On the 29th of August, Porter received an order a short time before sunset to attack Jackson, which he did not obey. General Pope was much aggrieved at this failure of Porter's, and in the November following preferred charges against him, under which he was court-martialed and dismissed from the service. Pope claimed that Porter's disobedience was willful and was the cause of his defeat; Porter justified his action on the ground that the order was received at too late an hour to make the attack successful, and that he had only exercised the discretion that is allowed to subordinate commanders in such emergencies, as his corps would certainly have been overwhelmed by the superior forces in front of him if he had made the attack as ordered. The justice of Porter's sentence was the subject of discussion for more than twenty years, and in the year 1886 he was restored to his rank of colonel in the United States army. From 1884 to 1888, he was police commissioner of New York city, and from 1893 to 1897 was cashier of the New York post office.

Por'ter, Horace, an American soldier and diplomat, was born at Huntingdon, Pa., April 15, 1837, and educated at West Point. He served during the Civil war as chief of ordnance in the army of the Potomac and in the army of the Cumberland, and as aid-de-camp to General Grant in the last year of the war. He was also General Grant's military secretary for a number of years, and later his private secretary. He reached the rank of brigadier-general during his career in the army, from which he resigned in 1873. In 1897, he was appointed ambassador to France, which position he has since filled.

Por'ter, Jane, author of *The Scottish Chiefs* and other works, was born at Durham, England, in 1776, daughter of an army surgeon, who died soon after her birth. She was brought up at Edinburgh and at London, and made a decided reputation, in 1803, by her romance, *Thaddeus of Warsaw*, which was followed by her most famous work, *The Scottish Chiefs*, in 1810. This work has a remarkable interest for youthful readers, and had the merit of inspiring Sir Walter Scott to write *Waverley*. Among her other works were, *The Pastor's Fireside*, *Tales Round a Winter's Hearth*, *The Field of Forty Footsteps*, etc. She died at Bristol, May 24, 1850.

Por'ter, Noah, president of Yale college, was born at Farmington, Conn., Dec. 14, 1811, and graduated at Yale college in 1831. After teaching for a number of years and taking a course in theological study, he became pastor of a Congregational church at New Milford, Conn., and afterward at Springfield, Mass. In 1846, he was elected professor of metaphysics and moral philosophy at Yale college, and after filling that position for 25 years, in 1871 he was chosen president of the institution, which position he held until the year 1886, when he retired and was succeeded by Dr. Theodore Dwight. He died at New Haven, Conn., March 4, 1892. Among Dr. Porter's numerous works are, *The Human Intellect*, *Books and Reading*, *Elements of Intellectual Science*, *Elements of Moral Science*, and an edition of *Kant's Ethics*. He was the editor of Webster's *Unabridged*, and of the *International Dictionary*.

Port'land, the largest city and chief port of entry in Maine, is situated on Casco bay, about 60 miles from Augusta, the capital of the state, and about 100 miles from Boston. A number of islands in the bay are included in the corporation, but the city proper is situated on a peninsula three miles in length and less than a mile in width. The Grand Trunk railroad and six other lines terminate at Portland, and there are regular lines of steamers connecting the city with New York, Boston, and other points on the Atlantic coast. The harbor, which is defended by three forts, is deep enough for vessels of all sizes, and is seldom frozen over. A large foreign trade is carried on with the West Indies, and also with European and South American countries, the value of both imports and exports amounting to several million dollars every year. Portland was first settled by an English colony in 1632. In 1866, a destructive fire swept over the city, destroying property to the amount of $10,000,000, but the burned district has long since been rebuilt. Population 50,145.

Port'land, the largest city of Oregon, is on the Willamette river, near where it joins the Columbia, about 100 miles from the ocean, and about 800 miles from San Francisco. It is a prosperous port of entry, large ocean ships coming up to this point. Clearing-house returns for 1900 show a total commerce for that year of over $100,000,000, with an export trade of $20,000,000. Portland was founded in 1844, and became a city in 1851. Population 90,426.

Port'land, Isle of, a rocky island or peninsula in Dorsetshire, England, connected with

the mainland by a long, narrow ridge called Chisel Bank. It is four and a half miles long, one and a half miles wide, and nine to ten miles in circumference. The coast line is rough and precipitous, the only landing place being on the north, opposite Weymouth. From its highest point, the Verne (495 feet in height), presents an almost unbroken slope to Portland Bill, the southern extremity, where stand two lighthouses, showing fixed lights 210 and 136 feet above the sea level. Between this point and the Shambles, is a dangerous reef three miles southeast, while a surf, called the Portland Race, is raised by the impetuous tides. By the construction of a magnificent "breakwater," over two miles in length, the building of which occupied twenty-three years, a harbor of refuge has been formed, affording anchorage for a large fleet of vessels. Population 11,000.

Port'land Vase, a celebrated ancient Roman glass vase or cinerary urn found during the pontificate of Urban VIII. (1623–44) in the Monte del Grano, near Rome. It was purchased by Sir Willian Hamilton in 1770, and a few years later by the Portland family, who deposited it in the British museum. The vase was broken into pieces by a lunatic in 1845, but the fragments were very skillfully united again. It is ten inches in height, and is the finest specimen of an ancient cameo cut glass that is known.

Por'to Rico (*rē'kō*), a West India island formerly belonging to Spain, first settled by Ponce de Leon in 1510. It is about 100 miles in length and 36 in width, and is traversed from east to west by ranges of mountains, from whose bases rich tracts of soil extend to the sea on all sides. Its estimated area is 3,600 square miles. Rain falls in much greater abundance on the northern than on the southern part of the island. The principal products are sugar, coffee, and rice, although tobacco, corn, yams, bananas, and tropical fruits are grown. The chief towns are San Juan, the capital, Mayaguez, and Ponce. The population of Porto Rico has increased from 155,400 in 1800, to about 953,243 in 1899. At the conclusion of the Spanish-American war, in 1898, Porto Rico was ceded to the United States. At present (1901) the island is under military rule, but legislation is in progress at Washington to secure for it representative government, with, if practicable, free trade between the United States and it. In May, 1900, an act of congress, designed to provide revenues and erect civil government, went then into effect.

Ports'mouth, the chief naval arsenal of Great Britain, is situate on the southwest shore of Portsea island, at the entrance to Portsmouth harbor, and opposite the town of Gosport, with which it is connected by a steam ferry. The fortifications of Portsmouth comcomprise, on the landward side, the outer line of the Portsdown forts and the Hillsea lines; to seaward, the Spithead forts. Portsmouth harbor, only about 400 yards wide at its entrance, expands into a spacious basin, extending inland about four miles, and having a breadth of three miles along its northern shore. This harbor is situated in the middle of the channel, close to the anchorage of Spithead, where 1,000 ships of the line may ride without danger or inconvenience, and is under the shelter of the Isle of Wight. Opposite to it is the French arsenal of Cherbourg. Population 115,000.

Ports'mouth, county seat of Scioto county, O., stands on the Ohio river at the mouth of the Scioto, 100 miles above Cincinnati. It has several iron foundries, rolling mills, and various manufactories, besides newspapers, schools, churches, etc. Population 17,870.

Ports'mouth, Va., the capital of Norfolk county, on the Elizabeth river, opposite Norfolk, with which city it is connected by ferry. Near by, at Gosport, is the Norfolk United States navy yard, on an islet of the Atlantic, south of Hampton Roads. It is served by the Atlantic and Danville, the Seaboard Air Line, and the Norfolk and Caroline railroads. It has steamship connection with Baltimore and the chief Atlantic seaports; it has dry docks, a naval hospital, and marine barracks. Here, too, are the shops of the Seaboard Air Line railroad. Population 17,427.

Por'tugal, a kingdom in Europe on the west side of the Iberian peninsula, about 350 miles in length, and from 70 to 140 miles in width. It is bounded on the north and east by Spain, and on the south and west by the Atlantic ocean. Total area, 36,038 square miles. The population increases steadily, but slowly. In 1851, it numbered only a little over 3,000,000; in 1874, it was over 4,000,000; and at the present time it may fairly be estimated at 5,050,000.

The most important mountain range of Portugal is the Sierra da Estrella, a westward continuation of the Spanish Sierra Guadarrama system; and the Sierra Morena is also continued westward in southern Portugal. Ocean breezes temper the climate of Portugal, and exempt it from the dry heat to which Spain is subject. The inequalities of surface, however, produce considerable diversities of climate; thus while snow falls abundantly on the mountains in the northern provinces, it is never seen in the lowlands of the southern districts, where spring begins with the new year and harvest is over by midsummer. The soil is generally fertile; but agriculture is in a backward state, little more than half the area of country being put to profitable use. The most prosperous branches of industry are the cultivation of the vine and the olive; from the former is derived the rich red wine, familiarly known as "Port," from its being shipped at Oporto, "the port." The total quantity of wine annually exported from Portugal amounts to 20,000,000 gallons.

Fish are abundant in all the rivers and off the coasts; and of late years attention has been given to the cultivation of oysters. The manufacturing industries of Portugal are chiefly concentrated in the two cities of Lisbon and Oporto. In all, about 90,000 persons are engaged in manufacturing pursuits, and nearly half of these are employed in weaving wool. In 1898, about 1,464 miles were open, of which 507 miles belonged to the state. The exports of the kingdom average about $32,000,000 annually, and the imports are nearly twice that amount. The chief mineral products include copper precipitate and copper ore, ore for sulphur, lead ore, and anthracite, and lignite. The national debt of Portugal has increased from about $100,000,000 in 1856 to about eight times that amount at the present time. Every male Portuguese over 21 years old is liable to service in the army — the term being three years with the colors and nine in the reserve. On a peace footing, the army embraces about 30,000 men, the war strength being about 150,000 men of all arms. The state religion is Catholic, but toleration is extended to all creeds. Education is superintended by a council and is entirely free from the control of the church. Compulsory education was enacted in 1844, but is not generally enforced; and therefore Portugal is far behind in education and intelligence. The one university, at Coimbra, established in 1290, is one of the oldest in Europe, and has 75 professors and nearly 1,300 students. Lisbon has a learned society, the Academy of Sciences, and a public library of 250,000 volumes.

Portugal is a constitutional monarchy, the crown being hereditary alike in the male and the female line. The parliament, or *cortes*, is composed of the house of peers and the house of deputies. The house of deputies consists of 138 members, elected by the people, elections being held every four years. The Portuguese differ greatly from the Spaniards, whom they regard with no small degree of hatred, mainly on account of attempts of Spain to subvert the independence of Portugal in the past. Lisbon and Oporto have a population, the former of 301,206, and the latter of 138,860; no other town in the kingdom reaches 30,000. The history of Portugal in ancient times, and for several of the first centuries of our era, was coincident with that of the Iberian peninsula as a whole; but in 1143 Alfonso I. made it an independent kingdom. During the latter part of the 15th century and the earlier part of the 16th, Portugal ranked as one of the most powerful monarchies in Europe, and Lisbon, the capital, was the distributing center of the products of the east, as well as one of its most important commercial cities. But from various causes it so declined and degenerated that in 1580 Philip II. annexed it to Spain. It remained subject to the Spanish monarchy until 1640, when after a forced union of sixty years, it succeeded in recovering its independence; and in 1668 its independence was formally recognized by the Spanish government. But, in her conflicts with Spain and the Netherlands, Portugal lost many of her colonies, and the nation which had once been the greatest maritime power on earth became one of the weakest and most insignificant. Under the reign of Joseph I., his minister, Pombal, sought to revive the national credit and restore the government to its former vigor and efficiency, but when Joseph's daughter Maria became queen, all progress was arrested. The insanity of Maria led, in 1799, to the establishment of a regency under her eldest son, John; and when that prince learned that Napoleon had resolved on the extinction of his dynasty, he left Portugal in 1807, and transferred the seat of government to Rio de Janeiro, in Brazil, which country at that time belonged to Portugal. Even after the French were driven out of Portugal, and Napoleon's power was broken, John continued to reside in Brazil, leaving Portugal to be governed by English officers — Marshal Beresford and others. This gave rise to such abuses and discontent that in 1820 a constitutional form of government was proclaimed at Lisbon in place of an absolute monarchy. John hurried home in this emergency, but was immediately forced to sign the new constitution, and to recognize the independence of Brazil, of which his son, Pedro, became emperor. On the death of John, in 1826, Pedro IV. organized the government after the model of the English, and then renounced the crown in favor of his daughter, Maria II., but in 1828, her uncle, Miguel, gathered around him a number of the clergy, army officers, and the old nobility, and was proclaimed king by the Cortes. Then ensued a period of great confusion and misrule; but in 1834 Miguel was overthrown, and renounced all pretensions to the crown. Maria II. remained queen until her death, in 1853, when she was succeeded by her son, Pedro V. Upon the sudden death of Pedro, in 1861, he was succeeded by his brother, Dom Luis, who continued to reign over the kingdom until he was succeeded by his son, Charles I., in 1889. The dependencies still owned by Portugal include Macao, in China; Timor, in the Malay archipelago; the Cape Verde islands; also those of St. Thomé and Principe, Portuguese Guinea, Portuguese East Africa, and Angola. See *Portugal* ("History of Nations" series), by Morse Stephens.

Poseidon, the Greek name for the mythical deity called by the Romans Neptune. He was said to be the son of Cronos (Time), and brother of Zeus. He was the husband of Amphitrite. He chose as his portion of the universe, the sea; and to the Greeks, surrounded by the sea, he naturally figures much in their literature and art. Under him are all other sea divinities. The waves are his horses; the trident, his scepter, and he is lord

of storms and giver of calm. He is usually depicted riding in his chariot; Zeus, as sitting upon his throne.

Po'sen, a province of Prussia, bounded north by West Prussia, east by Poland, south by Silesia, and west by Brandenburg. The province belongs to the great plain of north Germany, and there are several lakes in the east. About 60 per cent. of the area (11,184 square miles) is arable land and under cultivation, the principal products being grain, potatoes, and hops. Posen formed an integral part of Poland till 1772, when at the first partition the districts north of the Netze were given to Prussia; to these was added, in 1793, Great Poland, except Masovia, the whole being incorporated under the name of South Prussia. In 1807, Posen was included in the duchy of Warsaw; but it was reassigned to Prussia by the congress of Vienna in 1814, under the name of the Grand-duchy of Posen. Population 1,888,055, of whom 880,000 are Poles, and 725,000 Germans.

Po'sen, the chief town of the Prussian province of Posen, and a fortress of the first rank, is situated on the Warthe, 150 miles by rail from Berlin. In the 16th century, it was an important trading mart, but before the end of the same century it began to decline. The chief manufactures are artificial manures, agricultural implements, furniture, carriages, etc. Population 117,014.

Post-Mor'tem Exam'ination (Latin *post*, "after," and *mors*, "death"). Examination of the body after death is a duty which has to be performed by physicians in a variety of circumstances, of which the most important are (1) cases of sudden and accidental death, (2) cases of illness in which the nature of the disease could not be determined.

Post Office, the department of government whose business it is to convey letters, papers, books, and small parcels of merchandise from place to place. It is so called from the posts established along the roads of the Roman empire where couriers were placed in readiness for conveying news and dispatches. Some other ancient countries had similar posts; but in all cases they were for government service only, the carrying of private letters or dispatches being no part of their duties. The beginning of a postal service in the United States dates from the year 1639, when a house in Boston was employed for the receipt and delivery of letters for or from beyond the seas. In 1672, the government of New York colony established "a post to go monthly from New York to Boston"; and in 1702 it was changed to a fortnightly one. A general post office was established in Virginia in 1692, and in Philadelphia in 1693. A deputy postmaster-general for America was appointed in 1692; and by an act of parliament, in 1710, he was directed to keep his principal office in New York, "and other chief offices in some convenient place or places in other of her majesty's provinces or colonies in America." The system, however, was a comparative failure until Dr. Benjamin Franklin became postmaster-general in 1753. Franklin filled this office until the year 1774 with such ability and efficiency that when he was removed from the position in 1774 the net revenue of the department exceeded $15,000.

In 1789, when the new Federal government was organized, the number of post offices in the thirteen states was only about seventy-five. The following table will show the progress that was made during the first century of our history:—

Years.	No. of Offices.	Revenue.	Expenditures.
1790.....	75	$ 37,935	$ 32,140
1800.....	903	280,804	213,994
1810.....	2,300	552,366	495,969
1820.....	4,500	1,111,927	1,160,926
1830.....	8,450	1,850,583	1,932,708
1840.....	13,468	4,543,522	4,718,236
1850.....	18,417	5,552,971	5,212,953
1860.....	28,498	8,518,067	19,170,610
1870.....	38,492	19,772,221	23,998,837
1880.....	42,989	33,315,479	36,542,804
1890.....	62,401	60,858,783	66,645,083
1899.....	75,000	95,021,384	101,632,160

As will be seen, the expenditures of the post office department exceed the receipts, which is due to the fact that the postage on papers, books, etc., is so low that they must necessarily be carried at a loss, and also to the improvements that are made in the service from year to year. Some idea of the vast business of the department may be obtained from the number of letters, papers, etc., carried in the year 1890:—

Letters, postal cards, etc	2,289,950,015
Newspapers, etc	778,428,515
Other articles	519,247,199
Articles sent free of postage	376,509,165
Articles of all kinds for foreign countries	41,273,312

From the organization of the post office department until 1816, the rate of postage on letters varied, according to distance, from 8 to 25 cents. In 1816, these rates were changed so as to vary from 6¼ cents to 25 cents; and in 1845 the rate was reduced to 5 cents for each letter not exceeding ½ ounce in weight, and 5 cents for each additional ½ ounce or fraction thereof, carried for a distance under 300 miles; over 300 miles 10 cents. In 1851, the rate was made 3 cents for all distances under 3,000 miles, if prepaid, and 5 cents if paid on delivery. In 1855, a law was passed requiring all letters to be prepaid; and, in 1863, the rate was made uniform to all offices in the United States; and by act of congress, approved March 3, 1885, the rate was still further reduced to 2 cents for each ounce or fraction thereof, carried to any part of the United States or territories. The same rate is charged for drop letters where there is free delivery by carriers; where there is no such delivery, only one cent is charged.

Mailable matter is divided into four classes, of which letters and any matter sealed against

inspection constitute the first class. The second class embraces newspapers and all other periodicals issued regularly at least four times a year. The postage on matter of this class is one cent a pound, except that such periodicals may be sent to actual subscribers, living in the county where they are published, free of postage. Matter in the third class includes books, transient newspapers, and, in general, all printed matter, not issued periodically; it also extends to proof sheets and manuscript copy accompanying the same, and, in general, to any paper, cardboard, or parchment, on which an impression has been made by printing or other mechanical process, except the copying press or typewriter. The postage on matter of this class is one cent for each two ounces or fractional part thereof. The fourth class includes articles of merchandise, and, in general, all mailable matter not belonging by its nature to either of the other three classes, and the rate charged on it is one cent an ounce. The limit of weight is four pounds. Matter belonging to the first, third, or fourth class may be registered on payment of eight cents in addition to the postage. In 1864, the money-order system was established at the leading post offices of the country, which has been a great convenience to the public. The following are the rates charged: For sums not exceeding $5, 5 cents; over $5 and not exceeding $10, 8 cents; over $10 and not exceeding $15, 10 cents; over $15 and not exceeding $30, 15 cents; over $30 and not exceeding $40, 20 cents; over $40 and not exceeding $50, 25 cents; over $50 and not exceeding $60, 30 cents; over $60 and not exceeding $70, 35 cents; over $70 and not exceeding $80, 40 cents; over $80. and not exceeding $100, 45 cents. A single money order may include any amount from 1 cent to $100. During the fiscal year ending June 30, 1891, the number of money orders issued was 11,451,274, covering the sum of $119,122,236; fees for same, $1,104,457.

In addition to the money-order system, the 3-cent postal note was authorized by congress in 1883, and is issued at the uniform charge of 3 cents for any sum from 1 cent up to $4.99. This note is payable to any person holding the same at any money-order office in the United States, within three months from the last day of the month in which it is issued. During the year ending June 30, 1891, the number of postal notes issued was 6,802,558, covering the sum of $11,753,849.28, the fees for the same being $204,076.24.

The number of post-offices in the United States authorized to issue money orders and postal notes, July 15, 1892, was 14,858, of which number 2,296 were also international money-order offices. There were at the same date 718 post offices authorized to issue postal notes only.

The one-cent postal card was first issued in 1873, large numbers of which are now used for brief communications. The two-cent card, with a "reply card" attached for the return of an answer, was first issued during the year 1892.

In 1864, the free-delivery system was introduced into the larger cities of the country, and it has since been extended to all towns and cities having over 10,000 inhabitants, or doing a post-office business of over $10,000. Provision has since been made for the extension of this system to villages and rural communities, and this has been accomplished to a limited degree. All post offices whose gross receipts amount to $1,000 or more are divided into three classes, first, second, and third, and are filled by presidential appointment; those whose receipts are less than $1,000 constitute the fourth class, and are filled by the appointment of the fourth assistant postmaster-general. The salaries of the postmasters appointed by the President vary from $1,000 to $6,000, according to the amount of business transacted. The salaries of fourth-class postmasters are derived from the percentage allowed on the sale of stamps, etc.

By the action of an international postal convention, which met at Berne, Switzerland, in 1874, the postage on all letters between the countries included in that union, as well as those that have since joined it, was fixed at the uniform rate of five cents on each letter weighing one half-ounce.

Among other improvements in the United States postal service that have been discussed but not yet adopted, are postal savings banks, the reduction of letter postage to one cent.

Potassium (*po-tas'si-um*), a bluish-white metal discovered by Sir Humphrey Davy in the year 1807. It is the lightest of all the metals except lithium, and as its specific gravity is only .865, it readily floats on water. In so doing it reacts violently with the water, forming caustic potash, and giving off hydrogen, which ignites spontaneously from the heat of the reaction. At the temperature of 32° Fahrenheit it is brittle, like glass; at 59° it is soft and malleable; at 144° it becomes liquid. Potassium is widely diffused in the vegetable, animal, and mineral kingdoms. Some of the more important potassium compounds are caustic potash (the hydroxide), the carbonate, the bicarbonate; also potassium chloride, bromide, iodide, nitrate (saltpeter), sulphate, chlorate, cyanide, etc. Of these iodide, bromide, and chlorate are used for medicines, the others being employed more or less in the arts.

Pota'to, the tubers of *Solanum tuberosum*, a genus of the nightshade family, which contains about 900 species, distributed almost everywhere, but most abundant in tropical America. Only about 25 of these species are found in North America. The potato, from which numerous cultivated varieties have originated, came from Chile, and is native in the mountains as far north as southern Colorado. The importance of these tubers as an

article of food is well known. It is sometimes called "Irish potato" or "white potato," to distinguish it from the "sweet potato," which belongs to a totally different plant. The cultivated varieties of potatoes are exceedingly numerous, and additions to the list are being made yearly. That this tuber is a modified stem is apparent from the so-called "eyes," which are buds appearing in the axils of minute scales. As is well known, these buds are able to develop into new plants, so that in planting the tubers care is taken in cutting them to include one or more eyes. In 1900, the acreage in the United States of potato-raising was 2,611,054 acres, and the value of the year's crop was estimated at nearly ninety-one million dollars. The total number of bushels in the gross yield was two hundred and ten million.

Pota'to Bug or **Pota'to Bee'tle,** a widely known beetle infesting potato vines. In twenty-five years it spread over the country, from the Colorado region to the Atlantic coast, and from Virginia to Maine. Up to 1859, this insect fed upon the sand-bur, a wild plant related to the potato, but, about that year, began to appear upon the potato vine. It multiplied rapidly and migrated eastward, causing extensive destruction, and, in 1874, had reached the Atlantic coast. It has been combatted with paris green and is now fairly well under control. The last part of its name (*Doryphora decemlineata*) refers to the ten dark lines on the wing covers.

Potential (*pō-tĕn'shal*), a term employed in physics, astronomy, and electric engineering. The region round about any attracting body where work has to be done to carry mass from one point to another is known as a field of force. The potential at any point in such a field of force is defined as the amount of work required to bring up a unit mass from infinity to that point. It is to be noted that nothing is here said as to the path by which this unit mass is brought up, for the work is the same whatever the path, provided the attraction obeys the law of inverse squares. This quantity was first introduced into physics by Laplace in his *Mécanique Céleste;* but the name, *potential,* is due to George Green (1828). The enormous importance of this quantity in electrical science will be appreciated best by reading some such treatment as J. J. Thomson's *Elements of Electricity and Magnetism.*

Poto'mac, a river of the United States, formed by two branches which rise in the Allegheny mountains in West Virginia, and unite 15 miles southwest of Cumberland, Md., from which point the river flows in a southeasterly course 400 miles, and empties into Chesapeake bay, after forming an estuary 100 miles long and from two to seven miles wide. A few miles above Washington, it forms a cataract, 35 feet high, and between this and Westport it falls more than 1,000 feet. The scenery in this portion of its course is wild and beautiful, especially where it passes through the Blue Ridge at Harper's Ferry. The Potomac forms a great part of the boundary line between Virginia and Maryland.

Potosi (*pō-tō-sē'*), a city of Bolivia, South America, nearly 50 miles southwest of Chuquisaca (Sucre). It is built on the side of the Cerro de Potosi, 13,000 feet above the level of the sea, and is one of the loftiest inhabited places on the earth. The streets are too steep or narrow for wagons or carriages, and fully one-half of the town is composed of tottering and ruined buildings, uninhabited and desolate. There are considerable changes in the climate, but it is generally very cold, owing to the snow on the surrounding mountains, which scarcely ever melts. Yet Potosi is one of the principal commercial towns of South America, the industry of the place being limited to silver mining. As the country near Potosi is very unproductive, all supplies have to be brought from a distance. The town was founded in 1545, and in 1611 had 160,000 inhabitants, but its population at the present time does not exceed 16,000. The department of Potosi is rich in minerals and cattle, and has an area of 52,100 square miles, and a population of 250,000.

Potpourri (*pō-pör-ē'*), the name of a mixture of sweet-scented flowers, dried and placed in a vase with a perforated lid, so that their odor may be diffused through the room in which they are placed. But it also signifies a dish of different viands, and corresponds in this sense to the *hotch-potch* of Scotland and the *olla podrido* of Spain. In music, the name is applied to a selection of pieces strung together without much system or arrangement—a sort of medley.

Pots'dam, the chief town of the Prussian province of Brandenburg, and second residence town of the royal family of Prussia, is situated on an island beside the river Havel, sixteen miles by rail from Berlin. It is a handsome city, with broad streets, public gardens, and fine squares, and in the neighborhood of the town are more than half a dozen royal palaces. The manufactories of Potsdam include sugar, chemicals, harness, silk, waxcloth, beer, etc. Flower gardening, especially of violets, is an active industry. The illustrious Alexander von Humboldt was a native of the place. Potsdam owes its creation as a town to the great elector Frederick William and to Frederick II. Prior to that period it was only a fishing village, built on the site of an ancient Slav settlement. Population 58,455.

Pot'stone, a mineral composed of a mixture of talc, mica, and chlorite. It is soft and easily cut when newly dug up, but becomes hard after exposure to the air. It is made into pots and other utensils, which are cleaned by the fire. It was well known to the ancients,

and Pliny describes the manner of making vessels of it. It is quarried in Moravia, Norway, Sweden, Greenland, etc.

Pottawat'tomies (signifying fire-makers), a tribe of North American Indians, belonging to the Algonquin stock. The early French settlers established a mission among them at Green Bay, Wis., and to this day many of them are Roman Catholics. They sided with the English both during the Revolution and in the War of 1812, and afterward settled in Kansas, where one band of over 400 now live in houses and cultivate the ground. Another band, 500 in number, is on a reservation in the same state, under the care of the Society of Friends.

Pot'ter, Alonzo, an American bishop of the Protestant Episcopal church, was born at La Grange, N. Y., July 10, 1800. He graduated at Union college in 1818, and a year later became a tutor in that institution, being afterward elected to the professorship of mathematics. Entering the ministry of the Protestant Episcopal church, he became rector of St. Paul's church at Boston in 1826, and in 1845 was chosen bishop of the diocese of Pennsylvania, a position which he filled with rare fidelity and efficiency, until he died at San Francisco, July 4, 1865. Among his works are *Political Economy*, *Religious Philosophy*, and *Handbook for Readers and Students*.

Pot'ter, Henry Codman, an American clergyman, was born at Schenectady, N. Y., May 25, 1835, and educated at Union college. His theological course was taken in the seminary at Alexandria, Va. His first service in the ministry was in a small village of Pennsylvania, from which charge he was called to St. John's Church, Troy, N. Y. After serving there and in Trinity, Boston, he was made rector of Grace church, New York city, where he remained until consecrated assistant bishop of New York, in 1883. In 1887, the death of his uncle Horatio, then bishop, placed upon him the whole responsibility of that office. He has published several works, among which may be mentioned *Sisterhoods and Deaconesses*, *The Gates of the East*, or a *Winter in Syria and Egypt; Sermons of the City*, etc. He has taken very prominent part in the attempts to purify the municipal politics of New York city and excited the animosity of those classes which are accused of sheltering vice for a remuneration.

Pot'ter, Paul, the greatest animal-painter of the Dutch school, was born at Enkhuizen in 1625, and was the pupil of his father, Pieter Potter, a landscape-painter, with whom he came to Amsterdam in 1631. He was also an excellent etcher and was so precocious that his best-etched pieces, *The Herdsman*, and *The Shepherd*, were finished when he was only eighteen years old. He established himself at The Hague in 1649, but in 1653 he returned to Amsterdam. He died there in 1654, at the untimely age of twenty-nine. His *Dairy Farm*, measuring 48¼ by 19½ inches, was sold in London in 1890 for $30,450, or $65 per square inch.

Pottery, a term applied to all objects made of baked clay. This art is of high antiquity, being practiced among various races in prehistoric times. We find mention of earthenware in the Mosaic writings. The Greeks had important potteries at Samos, Athens, and Corinth, and attained great perfection as regards form and ornamentation. Demaratus, a Greek, the father of Tarquinius Priscus, king of Rome, is said to have instructed the Etruscans and Romans in this art. The Arabs seem to be entitled to the credit of having introduced the manufacture of glazed ware into modern Europe. The Italians are said first to

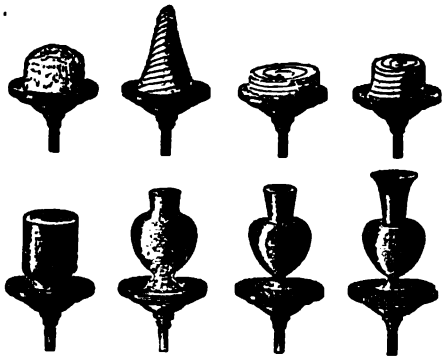
ETRUSCAN VASES.

have become acquainted with this kind of ware as it was manufactured in the Island of Majorca, and hence they gave it the name of *majolica*. They set up their first manufactory at Faenza in the 15th century. In Italy the art was improved, and a new kind of glaze was invented, probably by Luca della Robbia. The French derived their first knowledge of glazed ware from the Italian manufactory at Faenza, and on that account gave it the name of *faience*. About the middle of the 16th century the manufactory of Bernard Palissy at Saintes in France became famous on account of the beautiful glaze and rich ornaments by which its products were distinguished. A little later the Dutch began to manufacture at Delft the more solid but less beautiful ware which thence takes its name. The principal improver of the potter's art in Britain was Josiah Wedgwood in the last century. Porcelain or chinaware first became known in Europe about the end of the 16th century through the Dutch, who brought it from the East. In the United States the manufacture of pottery and porcelain is of recent development, but has already attained considerable dimensions, the leading establishments being located at Trenton, N. J., Cincinnati, Akron, and East Liverpool, O.

There are certain general principles and processes which are common to all kinds of pottery and porcelain. The first operations are connected with the preparation of the potter's paste, which consists of two different ingredients, an earthy substance, which is the

clay proper; and a siliceous substance, which is necessary to increase the firmness of the ware, and render it less liable to shrink and crack on exposure to heat. The clay is first finely pulverized, and reduced to the consistency of cream, when it is run off through a set of wire, gauze, or silk sieves into cisterns, where it is diluted with water to a standard density. The other ingredient of the potter's material is usually ground flints, or flint powder, as it is called, which treated in much the same way as the clay, is finally passed as a creamy liquor into a separate cistern. These liquors are now mixed in such measure that the dry flint-powder bears to the clay the proportion of one-sixth or one-fifth, or even more. The mixture is then forced into presses, lined with cloth, by means of a force-pump, the cloth retaining the clay and allowing the water to escape. The clay now forms a uniform inelastic mass, which is cut into cubical lumps and transferred to a damp cellar, where it remains until a process of fermentation or disintegration renders it finer in grain and not so apt to crack in the baking. It is then subject to another operation, called *slapping* or *wedging*, which consists in repeatedly breaking the lumps across and striking them together again in another direction, dashing them on a board, etc. This final process of incorporation is now most frequently performed by machinery.

In making earthenware vessels, if they are of a circular form, the first operation after the paste has been made is turning, or what is technically called *throwing* them on the wheel.



Successive Stages of Earthenware Vessel on the Potter's Wheel.

This is an apparatus resembling an ordinary turning-lathe, except that the surface of the *chuck*, or support for the clay, is horizontal instead of vertical. The chuck is in fact a revolving circular table, in the centre of which a piece of clay is placed, which the potter begins to shape with his hands. The rotary motion of the table gives the clay a cylindrical form in the hands of the potter, who gradually works it up to the intended shape. It is then detached from the revolving table and dried, after which, if intended for finely-finished ware, it is taken to a lathe and polished. It is at this stage that the handles and other prominent parts are fitted on, which is done by means of a thin paste of clay called *slip*. The articles are now removed to a room in which they are dried more thoroughly at a high temperature. When they have reached what is called the *green* state they are again taken to a lathe and more truly shaped, as well as smoothed and burnished. When the articles are not of a circular form, and accordingly cannot be produced by means of the wheel, they are either pressed or cast in moulds of plaster of Paris.

When shaped and dried the articles are ready for the kiln, in which they are exposed to a high temperature until they acquire a sufficient degree of hardness for use. After the kilns have been allowed to cool very slowly, the articles are taken out, and if they are not to be decorated in color, and sometimes also when they are to be so decorated, they are immersed in a composition called *glaze*, which, after the vessels have been a second time subjected to heat, is converted into a coating of glass, rendering the vessels impermeable to water.

There are two methods of printing on earthenware: press-printing, which is done on the bisque, and bat-printing, done on the glaze. In both cases an engraving is first executed in copper, and thence transferred, by means of a sheet of paper containing an impression, to the article requiring to be printed; but the processes are slightly different in detail. When the vessel has received its impression it is ready to be fired in the enamel kiln. Painting on earthenware is effected with a brush over the glaze.

Porcelain or chinaware is formed only from argillaceous minerals of extreme delicacy, united with siliceous earths capable of communicating to them a certain degree of translucency by means of their vitrification.

The processes employed in manufacturing porcelain wares are very much the same as those used for other kinds of earthenware, but requiring more delicacy and care. Metallic oxides incorporated with some fusible flux, such as borax, flint, etc., are used for painting on porcelain. The colors are mixed with essential oils and turpentine, and applied by means of a camel's-hair brush. When the painting is finished the vessels are baked in a peculiar kind of ovens called *muffles*, which are also used for fixing the printed figures on the glaze of stoneware. In order to secure the desired tint the baking must be stopped at precisely the proper time.

Potts'town, Pa., a borough in Montgomery county on the Schuylkill river and canal, and on the Philadelphia and Reading, and the Pennsylvania railroads, 18 miles southeast of Reading and 40 miles northwest of Philadelphia. Here are the plants of the Philadelphia Bridge company, and of the Pottstown Iron company, together with many

industrial establishments for the manufacture of nails, pig-iron, boilers, carriages, agricultural implements, cigars, etc. It has some schools, including the Hill school, the Normal institute, besides churches, libraries, banks, and other civil institutions. Population 13,696.

Potts'ville, Pa., a borough, the capital of Schuylkill county, on the river of the same name, in the rich anthracite coal regions of the state, 35 miles northwest of Reading, and 92 miles northwest of Philadelphia. It was at the Pottsville furnaces that hard coal was first successfully used for smelting purposes in 1839; it continues to be notable not only as a shipping-point for anthracite coal, but as an industrial center; there are rolling, spike, and planing mills, stove foundries, nut and bolt factories, machine and engine shops, silk, skirt, and stocking factories, breweries, etc. Population 15,710.

Poughkeepsie (*pō-kip'si*), a city of New York state and county seat of Dutchess county, is situated on the east bank of the Hudson river, 65 miles by rail from New York city. The Hudson is here crossed by a steam ferry and spanned by a railroad bridge of masonry, steel, and iron. Poughkeepsie is the largest town between New York and Albany; its manufactures include machinery, ironware, silks, boots and shoes, clothing, etc., and it has a rolling-mill, a blast furnace, and several breweries. Two miles to the north of the city, is the state hospital for the insane, which cost $750,000; but Poughkeepsie has chief reason to be proud of its educational facilities. The famous Vassar college is just beyond the eastern limits of the city, and the town also contains a collegiate institute, a business college, and a number of academies and seminaries, besides the public schools. Population 24,029.

Poul'try (Latin *pullus*, "a chicken"), the term used to designate the birds domesticated by man, usually embracing chickens, ducks, geese, turkeys, and guinea fowl. From the time when men began to abandon their wandering mode of life and settle down in fixed habitations, poultry in some form or other has taken the place of the wild birds which they are no longer able to snare and kill. Poultry are raised for the food furnished by their flesh and their eggs. Their flesh enters largely into the food-supply of the country, and is both healthy and nutritious. It has been estimated that the daily consumption of eggs in the United States is 50,000,000, which would represent an annual value of $200,000,000.

In France, where poultry are bred to so great an extent, — the sale of eggs amounting to about $30,000,000 annually, — there are no poultry farms, in the exclusive sense, but fowls are kept by every farmer and cottager. The same remark applies to Italy, Denmark, and Ireland, all of which export large quantities of both eggs and poultry. In the wine districts of France, fowls are permitted to wander among the vines nearly all the year round, and they do excellent service in cleaning off insects, as well as in manuring the ground. To make poultry profitable, they should be well housed and well fed, with sufficient space for obtaining gravel, grass, worms, garbage, etc. Their houses should also be kept clean, as the richness of their manure makes the ground very foul. For laying hens it has been found that soft food is very beneficial, and that it should be given in the morning, with hard corn in the latter part of the day. Sitting hens should have a quiet nest, where they will not be disturbed during the twenty-one days required for incubation. Artificial incubation has been very largely adopted by poultry raisers, most of the machines now sold working with great precision and regularity. The advantage of incubators is that they can be worked at all seasons of the year.

Pound, the English form of the Latin word, *pondus*, meaning weight, is now used in two distinct senses, *first*, a gold coin having the value of 20 shillings and, *second*, a standard of mass, equivalent to 7000. grains or 0.45359265 kilograms. The standard pound is not a "weight," but a "mass," and is kept at the Standard's office in London. The pound described above is the Avoirdupois pound; the Troy pound used only rarely by dealers in precious stones and metals has 5760. grains in it. (See Mass.) The old English pound, which is said to have been the standard of weight from the time of William the Conqueror to the time of Henry VII. was derived from the weight of 7,680 grains of wheat all taken from the middle of the ear and well dried. The pound weight of silver, the common money standard among the ancient Romans, was introduced by them into the countries which they conquered, and thus the term "pound" became the designation of a certain amount of coined money. The English pound is now considered as the simple equivalent in value of twenty shillings; but it originally denoted the actual pound of silver that was coined into twenty shillings. From the time of Edward II. the coins were more and more diminished in size until the reign of George I., when the pound (in weight) of silver was coined into 66 shillings; and this rate still continues, the term "pound" meaning 20 of these shillings.

Pout'er. See Pigeon.

Pow'derly, Terence Vincent, an American labor leader, who came into prominence as General Master Workman of the Knights of Labor, was born at Carbondale, Pa., Jan. 22, 1849. He entered the employ of the railroad as a switch-tender at the age of twelve, and as a machinist at nineteen. While in this latter employment at Scranton, he was elected secretary of the Machinists' and Blacksmiths'

union, retaining that office until 1880. He was a delegate to the International Union at Louisville, Ky., in 1874. He joined the Knights of Labor in that year and was elected mayor of Scranton in 1877, and again in 1878. He was raised to the chief office in the Knights of Labor at their meeting in Chicago in 1879, remaining master workman until succeeded by James R. Sovereign in 1893. It was through Mr. Powderly's persistence that the Knights of Labor became an open instead of a secret organization. He studied law and was admitted to the bar in 1894, and threw himself actively into politics as a Republican. He was appointed commissioner of immigration by the late President McKinley in 1897.

Pow'ell, John Wesley, an American geologist and anthropologist, was born at Mount Morris, N. Y., March 24, 1834, and served through the Civil war, in which he lost his right arm and rose to the rank of major. After filling the chair of professor in the Wesleyan university at Bloomington, Ill., for a number of years, in 1870 a survey of the Colorado river and its tributaries was placed under his direction by act of congress. While engaged in this service he gave special attention to ethnology, and in 1879 was made director of the new bureau of ethnology; in 1881 he was also appointed director of the United States Geological survey. Major Powell received the degree of doctor of philosophy from Heidelberg in 1886, and the degree of doctor of laws from Harvard in the same year; and in 1887 was president of the association for the advancement of science. His works include *Explorations of the Colorado River*, *Lands of the Arid Region of the United States*, *Studies in Sociology*, *Contributions to North American Ethnology*, and *Outlines of the Philosophy of the North American Indians.*

Pow'er, a term used in physics and engineering to denote the *rate of work.* When an engine hoists a carload of coal from the bottom of a pit to the surface of earth, it does the same amount of work whether the hoist be made in one minute or in one hour. Yet there is a very great difference between these two cases; and we say that it requires a much more "powerful" engine to make the hoist in one minute. Accordingly, we define the *power* of an agent as the rate at which it does work, that is, the ratio of the work divided by the time. *Activity* is used as a strict synonym for power.

The *unit of power* most frequently employed in England and America is the "horse-power," introduced by James Watt and defined as the activity of an agent capable of raising 550 pounds through a vertical distance of one foot in one second. The French horse-power is such that it will raise 75 kilograms one meter per second. In purely scientific work the unit of power is that which will accomplish the work of *one joule per second.* This unit is called a *watt;* and is numerically equal to 10^7 *ergs per second.* In electrical work, the kilowatt, or one thousand watts, is the unit most frequently used. Electrical energy, whether for lighting or for power purposes, is sold at so much "per kilowatt-hour." It is important for the student to remember that one horse-power is equal to 746 watts.

Pŏw'ers, Hiram, a distinguished American sculptor, was born at Woodstock, Vt., July 29, 1805. While still a boy he went to Cincinnati, O., where he became an apprentice to a clock maker, and about the same time formed the acquaintance of a German sculptor, who taught him to model in clay. In 1835, he went to Washington, where he executed the busts of several distinguished persons. Two years later, he went to Italy to study his art, and resided in Florence until his death, which took place June 27, 1873. There he produced his statue of *Eve*, and numerous other works; but the famous production of his genius was the *Greek Slave*, of which six copies in marble and innumerable cast copies were produced.

Powhatan (*pow-ha-tăn'*). See POCAHONTAS.

Poyn'ter, Sir **Edward J.,** an English artist, was born at Paris, March 20, 1836. His father was an architect and his great-grandfather a well-known sculptor. He was a student at Brighton college, and even while an undergraduate was interested in art. It was while spending a winter in Madeira for his health (1852–53) that he determined to devote his attention wholly to art. Going to Rome soon after, he was encouraged by those he met; and in 1856 he pursued his studies in Paris at l'École des Beaux-Arts. In 1859 he exhibited at the British institution his *Pifferari*, the painting receiving much praise. During the following years his pictures were exhibited in the chief salons of Europe, and in 1871 he was elected professor of art at University college, London. Having been for some time a member of the Royal academy he was elected to its presidency in 1896, invested with the insignia of office, and knighted at Windsor, Nov. 26 of that year. Among his most celebrated paintings perhaps the best known is his *Atalanta's Race* (1876), but his mosaics in the house of parliament at Westminster have attracted favorable attention. He has made numerous stained windows, designed coins, etc., and he wrote and published *Ten Lectures on Art.*

Pozzuoli (*poz-zu-ō'lē*), a city of southern Italy on the bay of Naples, seven miles from the city of Naples, with which it is connected by a tramway. Pozzuoli is particularly interesting from its memorials of ancient times. Its cathedral was the temple of Augustus. There are the remains of an amphitheatre which seated 30,000 persons, and in which

Nero fought as a gladiator; also remains of temples to Diana and Neptune, and of the ancient harbor of Puteoli. Some of the pillars of the temples of Serapis, still standing, are much eaten into by the water animals, which form holes in solid rocks in which they lodge themselves, showing that this volcanic coast was for a considerable time submerged to a depth of several feet below the sea level, and subsequently upheaved again. Part of the ruins of the temple are still under the sea level. Population 13,000.

Præ'tor, the title given to the consuls of ancient Rome as leaders of the armies of the state; but it was specially employed to designate a magistrate whose powers were scarcely inferior to those of a consul. The prætor's functions were chiefly judicial, his principal business (although he sometimes commanded armies in the field) being the administration of justice in matters both civil and criminal; and to the edicts of successive prætors the Roman law owes much of its development. Originally, there was but one prætor; but in 246 B. C., a second prætor was appointed to settle disputes that might arise between Romans and foreigners temporarily residing in Rome. In 227 B. C., two new prætors were appointed to administer affairs in Sicily and Sardinia, and a few years later, two for the Spanish provinces. Sulla increased the number to eight and Julius Cæsar to sixteen.

Præto'rian Guard, a special body of soldiers organized for protecting the person and upholding the power of the Roman emperors. We read of a select guard of soldiers attached to the person of Scipio Africanus, but it was by Augustus that they were first organized as a separate force. He formed nine or ten cohorts of 1,000 men each, but kept only three of them at Rome. Tiberius, however, assembled the nine cohorts in a permanent camp at Rome, while Vitellius increased their number to sixteen cohorts. They soon acquired great power, which they exercised often in a most unscrupulous manner, elevating and deposing emperors at their pleasure. Candidates for the imperial dignity found it necessary to bribe them largely; while those who attained the position were accustomed to purchase their favor by liberal donations. After the death of Pertinax (193 A. D.) they sold the imperial purple to Didius Julianus for a sum of money; but in the same year their organization was broken up by Severus, who formed new cohorts out of the best legions serving on the frontiers, which he increased to four times the number of the old. After several other changes the prætorian guard was finally dispersed among the other Roman legions by Constantine the Great in the year 312.

Pragmat'ic Sanc'tion, a solemn ordinance of the head of a kingdom relating either to affairs of church or those of state. The term originated in the Byzantine empire, and signified a public and solemn decree by a prince, in distinction from the simple rescript, which was a mere declaration of law in answer to an individual. This name is applied to several important treaties, of which the chief ones are (1) that of St. Louis in 1269, and (2) that of Charles VII. in 1437, in both of which the rights of the Gallican church were asserted; (3) the instrument which settled the empire of Germany in the house of Austria in 1439; (4) the ordinance by which Charles VI., emperor of Germany, settled his dominions on his daughter, the archduchess Maria Theresa; (5) the settlement of the succession of the kingdom of Naples, which was ceded by Charles III. of Spain, in 1759, to his third son and his descendants.

Prague, the capital of Bohemia, and the third largest town in Austria-Hungary, is situated on the Moldau, 220 miles from Vienna, and 120 from Dresden. It offers a highly picturesque appearance, from the beauty of its site and numerous towers, more than 70 in number, which rise above the many noble palaces, public buildings, and bridges of the city. The fortifications have been gradually demolished since 1866. The university, founded in 1348, received a new constitution in 1881, and now has two coordinate sides or sections, one German and one Czech, with 1,100 and 2,600 students, respectively. At Prague there is also a government technical high school, with 1,300 students, and teachers of both nationalities, German and Bohemian. The city has at various times been ravaged by wars, and here peace treaties have been enacted, notably that of 1635 between Ferdinand II. and the Elector of Saxony, and that of 1866 between Prussia and Austria, when the latter ceded to Prussia her rights in Schleswig-Holsten, and paid her a war indemnity of fifteen million dollars. Population 190,000.

Prai'rie (French, a "meadow"), the name by which the French explorers called the great fertile and treeless plains lying between Ohio and Michigan on the east, and the desert plains on the west. They embrace the western part of the state of Ohio, nearly all of Indiana, Illinois, and Iowa, the southern part of Michigan, the northern part of Missouri, and parts of Wisconsin, Kansas, and Nebraska. These prairies vary from 100 to 1,000 feet in height. At Cairo, Ill., they are from 400 to 550 feet above the sea, while near the center of the state they average from 650 to 750 feet, and in the northern part they are from 800 to 900 and even 1,000 feet. In southern Wisconsin, the highest points are 1,100 feet above the sea, while near Prairie du Chien the prairies are only 400 feet high. In Iowa, the prairie tableland of Nicollet is from 1,400 to 1,500 feet above the sea, and divides the waters of the Missouri from those of the Mississippi. The prairies on the headwaters of the Illinois and Wabash rivers,

and south and west of Lake Michigan, are called flat, because very smooth and level, while the regions broken by depressions of streams are rolling prairies. Trees are seldom seen west of the Mississippi, and near the 98th meridian they disappear altogether. East of the Mississippi, they are found in scattered groves along the streams, or on low, rocky ridges. Prairies have almost no stones, the soil being a vegetable mould, black and very rich, producing wonderful crops of corn and wheat. The mound prairies near Puget Sound, and elsewhere along the Pacific coast, are thickly studded with earth mounds, from three to four feet in height, and from 30 to 40 feet in diameter at the base. The vast plains lying between the 99th and 104th meridians, and reaching from the Big Horn mountains south to the Llano Estacado, are arid and partly desert, although by irrigation they have recently been developed into fertile fields.

Prai'rie Dog, a species of marmot belonging to the ground squirrel family. The animal is in no sense a dog. They inhabit burrows on the western plains and prairies, throwing up hillocks, which often cover a large territory, making a "village." On the approach of travelers, the animals are seen perched, often erect, on their hillocks. There are two species, one living east and one west of the Rocky mountains; they are about a foot long, and their fur is of a pale chestnut brown color. They prefer sandy or gravelly soil, and make underground galleries of great extent. They feed on buffalo-grass. The small burrowing owl and a rattlesnake have been found in their burrows, but it is not now believed that this association is from choice, or is it harmonious.

Praxiteles (*prax-it'e-lēs*), one of the greatest sculptors of ancient Greece, of whose life little is known except that he was a citizen of Athens in the 4th century B. C. His principal works, most of which have perished, were statues of Aphrodite, Eros, Dionysius, Apollo, and Hermes carrying Dionysius. Feminine beauty and Bacchic pleasures were his favorite subjects, and in his treatment of these he displayed the greatest sweetness, grace, and naturalness. He has been justly called the sculptor of the beautiful.

Preces'sion, is the name given to the slow motion of the earth, which causes the equinoxes to recede slowly along the ecliptic (apparent path of the sun around the earth), so that the sun comes to them in its annual revolution a little *earlier* than it otherwise would. The cause of this motion is the attraction of the sun and moon upon the protuberant part of the earth about the equator — the equatorial diameter of the earth being 26 miles longer than the polar diameter. The moment of force thus exerted tends to tilt the earth, which, like a top, "precesses" instead of falling over. As this disturbing force on the earth is very small relatively to its mass, this turning of its axis about the pole of the ecliptic takes place at about the rate of 50.1″ per annum, and it therefore requires 25,868 years for the equinoxes to describe a complete circle on the ecliptic. See TOP, EARTH, and POLE STAR.

Pre'cious Stones. See STONES, PRECIOUS.

Pre-emp'tion. Under the laws of the United States, an actual settler on the public lands enjoys the right, in preference to any one else, of purchasing at a fixed price the land on which he has settled, to the extent of 160 acres. In the case of "offered" lands, the settler must file his "declaratory statement" within thirty days after entry, and within a year proof must be made of settlement and cultivation, and the land paid for at $1.25 per acre, if outside the limits of a railroad grant, or $2.50 if within such limits. If the tract settled on is "unoffered," an approved plan of the township must first be received at the district land office; the statement must then be filed within three months, and final proof and payment be made within thirty months thereafter. Title to land is thus obtained much sooner than under the homestead laws; but a homestead settler may at any time after six months purchase the land under the pre-emption laws; as, on the other hand, the holder of a pre-emption claim may convert it into a homestead.

Pren'tice, George D., a distinguished American journalist, was born at Preston, Conn., Dec. 18, 1802, and graduated at Brown university in 1823. After studying law and editing the *New England Review* for two years, in 1831 he became editor of the Louisville (Ky.) *Journal*, which position he continued to hold until his death in the year 1870. The *Journal* became famous under his editorship as an organ of the Whig party; and during the war it gave an unflinching support to the cause of the Union. Prentice's witty paragraphs also constituted a feature of the paper much noted and admired. He published a selection of these paragraphs in the year 1860, the title of the book being *Prenticeana*. He also achieved considerable reputation as a public lecturer, and was the author of a number of short poems. After his death, the Louisville *Journal* was consolidated with the *Courier* of the same city, under the name of the *Courier-Journal*.

Pre-Raph'aelitism, a term used by Holman Hunt, J. E. Millais, and W. M. Rossetti, three English painters of the 19th century, to denote their predilection for the great masters before the time of Raphael, who studied nature rather than technical rules and dogmas. The three artists above named as representatives of the pre-Raphaelite school, appeared in the exhibition season of 1849, Millais with *Lorenzo and Isabella*, Hunt with *Rienzi*, Rossetti with *The Girlhood of the Virgin*, and excited the most flattering attention; but

numerous critics and enemies arose, and in the third year of its existence the new school was threatened on all hands with the most powerful opposition. Happily, however, there appeared in the London *Times* three letters from Ruskin denouncing the spirit of jealousy and injustice with which the young men had been assailed, and pointing out the merits of their works, and the great influence for good which the revival of their principles was likely to have. There followed later a succession of pictures from the three artists, whose titles have become as familiar as household words.

Pres'burg, a town of Hungary, stand son the left bank of the Danube, 40 miles by rail from Vienna and close to the Austrian frontier. Its principal buildings are the cathedral, in which the kings of Hungary used to be crowned, the town house, the parliament house, etc. The chief manufactures are beer, dynamite, wire, starch, spirits, confectionery, etc. Presburg, or to give it the Czech name, Pozsony, was a prominent town during the 11th and 12th centuries, and was frequently chosen for conferences and meetings between the rulers of Austria and Hungary. From 1541 to 1784 it was the capital of Hungary. Population of the city, styled in Hungary Pozsony, 60,000.

Pres'cott, William Hickling, a distinguished American historian, was born at Salem, Mass., May 4, 1796, and graduated at Harvard college in 1814. During his college course his left eye was put out by a piece of bread playfully thrown by a fellow-student, and the other eye was soon sympathetically affected, so that he was obliged to live for several months in a darkened room. He next traveled in England, France, and Italy, married in 1820, and abandoned the study of law for literature, devoting himself to intense study, although he was able only to use his remaining eye a portion of the time. His first studies were in Italian literature; and it was not until 1826 that he entered on the work of his life, the study of Spanish history. After laboring with great patience for several years, in 1838 he issued his *History of Ferdinand and Isabella*, a work which at once gave him a brilliant reputation, both in America and in Europe, and was translated into French, Spanish, and German. In 1843, he published his *Conquest of Mexico*, and in 1847 his *Conquest of Peru*. In 1855, he published two volumes of his *History of Philip II.*, but before the third volume was completed he died of apoplexy at Boston, Jan. 28, 1859. Prescott's style alone would have given him great popularity; and to this day he is without a rival for clear and vigorous narrative and sustained power of color. He cannot be called a philosophical historian; but he is a master of narrative and incident, and there is not a dull passage in all his works. See his *Life*, by George Ticknor.

Pres'ident of the United States, the chief executive officer of the government, chosen by electors from the various states every four years. Nine Presidents — Washington, Jefferson, Madison, Monroe, Jackson, Lincoln, Grant, Cleveland, and McKinley have been chosen for two terms; but a third term, although not prohibited by the constitution, is practically prohibited by the popular prejudice against it. Any native male citizen of the United States over 35 years of age is eligible to the office of President. The salary of the office is $50,000 a year, but the President must receive no other emolument during his term from the United States or any state. He is commander-in-chief of the army and navy; has the power to grant reprieves and pardons for offenses against the laws of the U. S., except in cases of impeachment, and (by and with the advice and consent of the senate) to make treaties, appoint ambassadors, consuls, and all U. S. officers not otherwise provided for. Every bill which passes congress must have the approval of the President before it becomes law, unless two-thirds of both houses pass it over his veto. The President administers the government through heads of departments who are known as secretaries, and who constitute his cabinet. These officials are appointed by the President and confirmed by the senate. He also presents to congress, when it assembles, a comprehensive statement of the affairs of the nation, with suggestions as to such matters as need its action. See UNITED STATES, DEPARTMENTS OF.

Presidential electors are chosen by the states, each state being entitled to two electors at large, and one for each congressional district, the total number at the present time being 447. A majority of all the electors chosen is necessary to an election of President and Vice-president, and if no candidate receives such a majority the house of representatives must choose the President from the three highest numbers on the list, and the senate the Vice-president from the two highest. In the election of President by the house, the vote is by states, each state having one vote, and a majority of all the states being necessary to a choice. The two Presidents elected by the house of representatives were Thomas Jefferson in 1801, and John Quincy Adams in 1825.

The election of President and Vice-president — or rather the selection of presidential electors — occurs every fourth year, on the Tuesday after the first Monday of November; and on the second Monday of January following, these electors meet in the capitals of their respective states and cast their votes, and transmit the result of the same to the president of the senate. On the second Wednesday of February, the president of the senate counts the votes of all the states in the presence of both houses of congress and announces the result, and on the 4th of March thereafter, the persons so chosen for President

and Vice-president are inaugurated for the term of four years. In case of the death or disability of the President, the Vice-president becomes President, and assumes all the duties of the office during the term for which he was chosen Vice-president. If the office of President and Vice-president both become vacant, provision is made by law for filling the office of President from members of the presidential cabinet in the following order: (1) secretary of state, (2) secretary of the treasury, (3) secretary of war, (4) attorney-general, (5) postmaster-general, (6) secretary of the navy, (7) secretary of the interior, (8) secretary of agriculture.

The following is a list of the Presidents of the United States, with the years during which they filled the office: (1) George Washington, 1789–97; (2) John Adams, 1797–1801; (3) Thomas Jefferson, 1801–9; (4) James Madison, 1809–17; (5) James Monroe, 1817–25; (6) John Quincy Adams, 1825–29; (7) Andrew Jackson, 1829–37; (8) Martin Van Buren, 1837–41; (9) William Henry Harrison, March–April, 1841; (10) John Tyler (chosen Vice-president with Harrison), 1841–45; (11) James K. Polk, 1845–49; (12) Zachary Taylor, 1849–50; (13) Millard Fillmore (elected Vice-president with Taylor), 1850–53; (14) Franklin Pierce, 1853–57; (15) James Buchanan, 1857–61; (16) Abraham Lincoln, 1861–65; (17) Andrew Johnson (elected Vice-president with Lincoln in 1864), 1865–69; (18) Ulysses S. Grant, 1869–77; (19) Rutherford B. Hayes, 1877–81; (20) James A. Garfield, March—September, 1881; (21) Chester Allan Arthur (elected Vice-president with Garfield), 1881–85; (22) Grover Cleveland, 1885–89; (23) Benjamin Harrison, 1889–93; Grover Cleveland, 1893–97; (24) William McKinley, 1897–Sept. 1901; (25) Theodore Roosevelt (elected Vice-president with McKinley), whose term began on the death of McKinley, Sept. 14, 1901, and will expire March 4, 1905.

The following table shows the number of electoral votes allowed to each state since the census of 1890:—

Alabama	11	Nebraska	8
Arkansas	7	Nevada	3
California	8	New Hampshire	4
Colorado	5	New Jersey	10
Connecticut	7	New York	37
Delaware	3	North Carolina	10
Florida	3	North Dakota	2
Georgia	13	Ohio	23
Idaho	3	Oregon	4
Illinois	25	Pennsylvania	32
Indiana	15	Rhode Island	4
Iowa	13	South Carolina	9
Kansas	10	South Dakota	4
Kentucky	13	Tennessee	12
Louisiana	9	Texas	16
Maine	6	Vermont	4
Maryland	8	Virginia	12
Massachusetts	14	Washington	3
Michigan	14	West Virginia	5
Minnesota	9	Wisconsin	11
Mississippi	10	Wyoming	3
Missouri	16	Utah	3
Montana	3	Total	447

Press. See PRINTING.

Pres'sure, a term used in physics and in engineering to denote the force per unit area which a fluid exerts upon any surface. To obtain the total force which a fluid impresses upon any given surface we have, therefore, only to multiply the average pressure by the area of this surface. In pure science, the *unit of pressure* is that which exerts a force of *one dyne per square centimeter*. A larger, and often more convenient, unit is that which was adopted by the Paris congress of physicists in 1900, namely, one million dynes per square centimeter. This unit is practically exactly represented by the pressure exerted by a column of mercury 75 cm. high at sea level at O°C. This larger unit is called a *barye*. One barye = 10^6 C.G.S. units of pressure.

Pres'sure Gauge. See MANOMETER.

Preto'ria, the capital of the Transvaal, was formerly the seat of government of the South African republic, but was taken possession of by the British troops June 5, 1900. It was named after the Boer leader Pretorius. The town Pretoria lies 980 to 1,000 miles northeast from Cape Town, and 285 miles west from Delagoa bay. It is connected with both by railways. Its white population was estimated at 10,000 at the outbreak of the war with Britain. In 1896, the town was thoroughly fortified; and in 1899, the president of the republic sent an ultimatum to England demanding the withdrawal of all English troops from the neighborhood, and the submission of all questions at issue to arbitration. The troops from Pretoria immediately invaded the English colonies, and the war (elsewhere described) followed. See BOER WAR.

Pri'am, king of Troy at the time of the Trojan war, was the son of Laomedon and Strymo or Placia. The name means "the ransomed," and was given him on account of his having been ransomed by his sister Hesione from Hercules, into whose hands he had fallen. He was the husband of Hecuba by a second marriage, and had fifty sons, the best known of whom were Hector, Paris, and Troilus, and a daughter Cassandra. Priam is represented in Homer as too old to take an active part in the Trojan war, and only once appears on the field of battle. The oldest Greek legends are silent respecting his fate; but later poets, like Euripides and Virgil, say that he was slain by Pyrrhus when the Greeks stormed the city of Troy.

Prich'ard, James Cowles, English physician and ethnologist, was born at Ross, in Herefordshire, Feb. 11, 1786. After taking a thorough course in medical study and learning a number of foreign languages, in 1810 he commenced practice as a physician in Bristol. In 1813, he published *Researches into the Physical History of Mankind*, which at once gave him high standing as an ethnologist. The successive editions of this

work were further proofs of the zeal with which he continued his ethnological investigations. Being appointed a commissioner in lunacy, in 1845, he removed to London, where he died Dec. 22, 1848.

Pric'kle, a spiny outgrowth, such as those which occur on the stems of roses. They involve not merely the epidermis, but also more or less of the cortex beneath. See EMERGENCE.

Prim (*prēm*), **Juan,** a Spanish general, was born at Reus, in Catalonia, Dec. 6, 1814. He entered the army at an early age, and in 1843, on account of his services in overthrowing Espartero, he was made count of Reus and a general. In 1862, he was appointed to the command of the Spanish forces sent to Mexico, but soon withdrew his troops from the enterprise, his course being approved by the Spanish cortes when his reasons were given to that body. Failing in an insurrectionary movement in 1866, he fled to England and Brussels, but here he guided the movement that in 1868 overthrew the government of Queen Isabella. He was appointed war minister, with the rank of marshal, by Serrano, and soon became virtual dictator. In 1870, he selected Prince Leopold of Hohenzollern as Spanish king, which Napoleon III. made the pretext for his declaration of war against Germany. But as Leopold declined the crown offered to him, Prim prevailed on Amadeus, an Italian prince, to accept it; but on the day the new king landed in Spain, Dec. 28, 1870, Prim was shot, at Madrid, by an assassin, and died two days later.

Prime, Samuel Irenæ'us, Presbyterian minister and editor of the New York *Observer*, was born at Ballston, N. Y., Nov. 4, 1812, and graduated at Williams college in 1829. After studying theology at Princeton, he was ordained to the ministry and became pastor of a church on the Hudson river, opposite Newbury, N. Y. In 1840, he became the editor of the New York *Observer*, which position he held until his death, which occurred at Manchester, Vt., July 18, 1885. Besides his editorial writings, he published *Travels in Europe*, *Annals of the English Bible*, and numerous other works.

Prim'rose, a general name of species of the primrose family (*Primulaceæ*), but more specially applied to a species of the genus *Primula*, which includes about 150 species, most of which belong to the northern hemisphere. About 13 species are native to North America. The most common primrose of cultivation is the so-called Chinese primrose (*P. sinensis*), a downy house plant with enlarged calyx. The common "English cowslip," whose cultivated varieties are known as different kinds of "polyanthus," is *P. officinalis*. In the same family belong such forms as the beautiful "American cowslip" or "shooting star," and the very similar cultivated Cyclamen.

PRIMROSE.

Prince, a title given to the sons of kings, emperors, and other rulers, sometimes with a territorial addition, such as Prince of Wales, Prince of Orange, etc. In various parts of continental Europe, the title is borne by families of very high rank, but not possessed of sovereignty; but in England the term is restricted to members of the royal family. In a more general sense, the word "prince" is often used for any ruler or sovereign of a state.

Prince Ed'ward Island, the smallest of the provinces of the Dominion of Canada, is situated in the gulf of St. Lawrence and separated from New Brunswick and Nova Scotia by Northumberland strait. Cape Breton, to the eastward, shelters it from the boisterous Atlantic. The greatest length of the island is about 125 miles, its breadth varying from 4 to 34 miles. Total area about 2,000 square miles, with a population of about 55 to the square mile, or 103,258 in all. Although discovered by the Cabots, the island did not come into the possession of Great Britain until 1763. The surface is undulating, but never rises higher than 500 feet above the sea level. The soil is fertile, and all kinds of cereals, roots, and vegetables are raised. A natural manure, called mussel mud, formed from decayed shells of oysters, clams, and mussels, is found on the coasts of the island and is highly prized by the farmers. The coast line is a succession of bays and projecting headlands, the island being divided into three peninsulas by the three large bays of Egmont, Hillsboro, and Cardigan. Manufactures are not carried on to any large extent, although shipbuilding was an important industry previous to the substitution of iron and steel vessels for wooden ones. There is a government railway running from one end of the island to the other; there is also steam communication with the mainland, although it is sometimes interrupted in winter. In the Dominion senate the province is represented by four members, and in the house of commons by five. It has a government of its own, the local legislative assembly, with twenty-nine members, of which nine compose the

ministry or executive council, under a lieutenant-governor. Charlottetown is the capital and seat of government (population 12,080). The climate is temperate and healthy; the salubrity of the land is such that it is frequently called "the garden of the Dominion."

Prince of Wales is the title usually borne by the eldest son of the reigning sovereign of Great Britain. The monarchs of Wales during its independence were so designated, and upon its becoming a part of the realm of England the principality of Wales was bestowed by Henry II. upon his son, afterward Edward I. In 1343, the title was bestowed upon Edward the Black Prince, and from that time to the present the custom has been followed by each reigning sovereign of Great Britain. The title is not inherited but bestowed, and usually some time after the coronation of the sovereign. On the death of the Prince of Wales, the title has been transferred to the next heir apparent, if a male. An annuity of $200,000 was settled upon the Prince of Wales by 26 Vict. c. 1. By a statute, the Prince of Wales becomes a Knight of the Garter as soon as he receives the former title. The particular badge of the Prince of Wales is a design of three white ostrich feathers encircled by the ancient coronet of Wales, and accompanied by the motto "Ich dien" (I serve). This device is said to have been assumed by the Black Prince in 1346, when he took such a plume from John, King of Bohemia, whom he slew in battle. The origin of the motto has never been satisfactorily traced.

Prince'ton, a pleasant town in Mercer county, N. J., forty-four miles by rail from New York, and about the same distance from Philadelphia. On the 3d of January, 1777, it was the scene of a battle between the British under Colonel Mawhood and the Americans under Washington, in which the British were defeated. Here, the continental congress sat in 1773, and it was from Princeton that Washington dated his farewell address to his army. The place, however, is chiefly celebrated as the seat of the Presbyterian college of New Jersey, founded at Newark in 1746, but removed to Princeton in 1756. The second president of this college was Rev. Aaron Burr, father of Aaron Burr who afterward became Vice-president of the United States. Among its other presidents have been Jonathan Edwards and Dr. James McCosh; and among its graduates are some of the most distinguished names in American history. Since the Civil war the endowment has been largely increased, and the college now possesses five museums, two observatories, four laboratories, and libraries numbering 145,000 volumes. Princeton university has a faculty numbering about 100, with a student body of nearly 1,300. The Theological seminary, founded in 1812, has a full corps of professors and about 200 students. With this seminary is associated the fame of the *Princeton Review*, founded in 1825 and edited until 1872 by Dr. Charles Hodge, when it was united with the *Presbyterian Quarterly*, published in New York. Population of Princeton 3,899.

Prince'ton Univer'sity. The college of New Jersey, now known as Princeton university, was founded in 1746, being the fourth American college in date of founding. It was first opened at Elizabethtown in 1747, but the same year was removed to Newark and soon after to Princeton. Here in 1754–55 was erected the first college building, Nassau hall, famous as having been used as barracks, and as a hospital during the War of the Revolution. On Oct. 22, 1896, the 150th anniversary of the signing of the first charter, the title of Princeton university was assumed. The institution now includes the academic department, graduate department, and John C. Green school of science, including departments of civil and electrical engineering. Princeton has always held rank among the first educational institutions in the country. In the list of its instructors, past and present, and among its alumni are found the names of many distinguished men. Its present faculty numbers 91, with an attendance of 1,277 students.

Print'ing is the art of producing impressions from characters and figures on paper or any other substance, but in this article it is confined to the art of making impressions with movable types, which may justly be esteemed among the greatest of human inventions. But notwithstanding the importance of this invention, it is not certain to whom the credit of it belongs, as it is contested by the Holland-Dutch in favor of Lourens Coster, and by the Germans in favor of Johannes Gutenberg. The most general opinion would seem to be in favor of Gutenberg, but it is not unlikely that they both made the discovery at about the same time, which was during the first half of the 15th century. Between 1450 and 1455, Gutenberg printed a Bible, copies of which are still in existence, although exceedingly rare and valuable; and besides this Bible, some other specimens of work from his press at Mayence have been discovered. The Dutch at Haarlem preserve and show similar specimens of early printing by Coster. Mayence, Haarlem, and Strasburg were certainly the places where printing was done before the art was extended to Rome, Venice, Florence, and other European cities. The art was introduced into England in the year 1471 by William Caxton, who set up a press in Westminster Abbey.

The first printing press in the United States was set up in the house of the president of Harvard college at Cambridge, Mass., in the year 1639, and in 1674 another was established in Boston, after which other presses were gradually introduced throughout the colonies. Until the beginning of the 17th

century the press used was a screw press, with a contrivance for running the form of types under the point of pressure; force having been thus applied, the screw was relaxed and the form withdrawn, with the impression executed on the paper. The defects of this press were at length partially remedied by William Jansen Blaen, of Amsterdam, who invented a press in which the carriage holding the form was wound below the point of pressure, which was given by moving a handle attached to a screw, hanging in a beam having a spring, which spring caused the screw to fly back as soon as the impression was made. This kind of press, which was mostly of wood, continued to be used in every country in Europe, as well as in America, until the beginning of the 19th century. The first improvement on this press was made by the celebrated earl of Stanhope, who constructed a press of iron, and applied such a combined action of levers to the screw as to secure an easier and more efficient working. Numerous improvements succeeded this, the screw being dispensed with, and the pressure being effected by levers. The chief among these was the Columbian press, invented by George Clymer, of Philadelphia, in the year 1818.

Meantime, in the year 1811, Frederick König, a German printer, had invented a press in which the impression was given by a cylinder, the inking being done by rollers, and the paper being carried through the machinery on tapes. Mr. John Walter, of the London *Times*, was so favorably impressed with this method of printing that he engaged König to make a double cylinder press which should print two copies of a form at each revolution of the cylinder, but only on one side of the sheet. This press, which was completed in 1814, made about 1,800 impressions per hour, and was the first printing press in the world operated by steam power. A few years later, König invented an improvement on this press, in which the sheet, after an impression had been made on one side by one of the cylinders, was turned over to receive an impression on the other side by another cylinder; but the march of improvement did not stop here. The circulation of newspapers increased to such an extent that in 1855, Richard M. Hoe, of New York, brought out the rotary printing press, in which the pages of type were placed on a horizontal cylinder revolving on its axis, against which the sheets were pressed by a number of smaller cylinders, which were so arranged in a framework as to require a feeder for each one of these smaller cylinders. Such a press with six cylinders, each making 2,000 impressions an hour, could turn out 12,000 sheets, printed on one side, in an hour, and those with eight and ten cylinders in proportion. But the Hoe machine, with all its advantages, printed only one side at a time, and some years afterward — between 1863 and 1868 — the Walter press was devised, by which printing is done from a continuous roll of paper, which is printed on both sides from stereotype plates, cut in separate sheets and pasted. This press, when first introduced, printed from 12,000 to 15,000 sheets per hour; but since that time many other web-printing presses have been introduced, by which sheets of four pages are printed at the rate of 50,000 or more per hour. By the introduction of steam presses the trade of the printer has undergone a remarkable revolution in the past century, and although fewer hands are needed for working the presses in proportion to the amount of printing done than formerly, the increase of employment to compositors, bookbinders, etc., has been very great. The manufacture of printing machinery, as well as the manufacture of paper, has itself become a great industry, and no one can safely predict what progress will be made in this field during the present century. See *The American Dictionary of Printing and Bookmaking*.

Prism, an optical instrument composed of two plane refracting surfaces. The angle between these two planes is called the "refracting angle" of the prism. Since in any kind of matter, except ether, lights of different color travel with different speeds, it follows that lights of different color will each have a different direction impressed upon them on passing through a prism. A prism thus produces "dispersion" in a beam of white light and is used, therefore, in the spectroscope to separate the various colors which compose the incident beam. Any transparent material whose refractive index is desired is generally cut in the form of a prism; for on measuring the angle of deviation for any ray, call it D, and the refracting angle of the prism, which we may call A, we have the following relation: —

$$\text{Refractive index} = \frac{\sin\left(\frac{A+D}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$

See articles LUXFER PRISM, SPECTROSCOPE, and LIGHT.

Pris'oners of War are persons captured from the enemy during military or naval operations. In ancient times, the treatment of prisoners of war was very severe, it being no uncommon thing to put the population of a conquered city or state to the sword, or to reduce them to slavery. Although the practice of putting prisoners to death became less frequent, as the principles of Christianity became more widely diffused, they and their families were commonly reduced to slavery as late as the 13th century. By degrees the more humane custom of exchanging and paroling prisoners was adopted, although in all wars there is still more or less suffering among prisoners. The miseries endured by Union soldiers at Andersonville and other southern prisons during the Civil war fur-

nishes the darkest chapter in the history of that conflict.

Pris'ons, strange to say, are a development of civilization, and also of personal liberty. The abolition of slavery and the decay of the feudal system made it necessary in all countries to take the punishment of crimes out of private hands and turn the offender over to the power of the state. In the exercise of this power the various governments have punished their subjects by death, direct torture, transportation, exposure in the pillory, etc. All these, except death, have been abandoned by most civilized nations; and in all of them the death punishment is inflicted only for the most serious offenses; and as a consequence, imprisonment for a greater or lesser period is resorted to as a means of protection to society. How crudely, how barbarously, this power has often been exercised has in part been revealed to the world — and, if the whole story could be told, how dark would be the picture! It is a relief to turn from the contemplation of the miseries and horrors of prison-life to the efforts that are being made by prison reformers throughout the world to reduce prison discipline to a humane system, and to make it a means of reformation to the prisoner, as well as a means of protection to the public. The prisons of the world are yet very far from perfection; but in every civilized nation there are earnest men and women studying all the questions connected with prison reform, and the results are already seen in a more intelligible and more Christian system of discipline. In the United States, especially, our jails and penitentiaries have been relieved of many degrading features, and in a number of the states "reform schools" have been established for juvenile offenders. In the year 1877, the state of New York established a reformatory at Elmira for the reception of all prisoners under thirty years of age, in which, while strict order and discipline are maintained, the inmates are carefully trained and educated and encouraged to earn a parole, and even a discharge, by good conduct and thorough reformation. In the state of Ohio, in addition to a "reform school" for girls at Delaware and a "reform farm" for boys at Lancaster, an "intermediate penitentiary" has been established at Mansfield, O., which is conducted after the manner of the Elmira reformatory. Similar steps have been taken in other states. See *The State of Prisons in the Civilized World*, by Wines.

Pri'vateer, a ship owned by a private individual, or by a number of individuals, which, under letters of marque, makes war upon the shipping commerce of a hostile power. Privateering was abolished among European nations, except Spain, by the treaty of Paris in 1856; but the United States has never signed this agreement. During the War of 1812, and to some extent during the Revolutionary war, British commerce suffered severely at the hands of American privateers, there being over 200 of these afloat during the War of 1812. In the Civil war, the Confederate privateer, the *Alabama*, captured a considerable number of United States merchant vessels, for which England afterward paid damages for allowing a privateer to depart from one of her ports. By act of congress, passed in 1864, the entire proceeds of a prize taken by a privateer go to the captors, unless otherwise provided and specified in the ship's commission, the sum awarded being divided equally between the ship's company and her owners.

Priv'y Coun'cil, an institution peculiar to the English government, having its origin in feudal times, when it was the custom of the sovereign to summon his barons and nobles to give him advice in matters of state. The list of privy councilors includes, besides the prime minister and members of the cabinet, the archbishops of Canterbury and York, the bishop of London, the lord chief-justice of England, the lord-chancellor, and numerous dignitaries. In ordinary cases, only the cabinet ministers, the great officers, and the archbishop of Canterbury, are summoned to the meetings of the privy council, but in extraordinary cases the whole body is summoned.

In theory, the cabinet is only a committee of the privy council, but, in point of fact, power is exercised by the cabinet alone, and the privy council is only occasionally consulted, or consulted rarely. The privy council cannot, however, be truthfully described as dead or obsolete, as it still exercises important powers in special cases. In 1788, it took on itself the duty of inquiring into the sanity of George III., and in 1821 it determined the constitutional question of Queen Caroline's right to be crowned as queen consort. Still, in a general sense, it may be described as a reserve force, kept apart from the active and working forces of the government.

Proa (*prō'a*) is a peculiarly shaped canoe used by the natives of the Malay archipelago and on the China seas, especially by the Ladrone islanders. It is about thirty feet in length by three feet in width, and has the stem and stern equally sharp, so as to change its course without being turned around. One side is flat and in a straight line with stem and stern; the other side is rounded like an ordinary boat. This peculiar formation would make it easy to upset, were it not for a framework which projects to windward and supports a weight which counterbalances the great pressure of the wind on the sail.

Proc'ter, Adelaide Anne, daughter of B. W. Procter, was born at London, Oct. 30, 1825, and died there Feb. 3, 1864. By her *Legends* and *Lyrics*, some of them being first written for *Household Words*, she won no small measure of poetical renown.

Proc'ter, Bryan Waller ("Barry Cornwall"), was born at London, Nov. 21, 1787. Educated at Harrow with Byron and Peel for school-fellows, he came to London, when about twenty years of age, and soon began to contribute poetry to the *Literary Gazette*. A few years later, he published four volumes of poems, and produced a tragedy at Covent Garden theatre, whose success was largely due to the acting of Macready and Kemble. He was a metropolitan commissioner of lunacy from 1832 to 1861, and died Oct. 4, 1874. His works, issued under the pseudonym of "Barry Cornwall," comprise *Dramatic Scenes*, *A Sicilian Story*, *Marcian Colonna*, *The Flood of Thessaly*, and *English Songs*, besides *Memoirs of Kean*, and *Charles Lamb*. Although "Barry Cornwall" cannot be assigned to a place in the front rank of literary genius, he will long be remembered as an author whom every one loved; in the language of Mr. Gosse "he has written more songs that deserve the comparative praise of *good* than any other modern [English] writer, except Shelley and Tennyson." See *Bryan Waller Procter, an Autobiographical Fragment*, edited by Coventry Patmore.

Proc'tor, Richard Anthony, a distinguished English astronomer, was born at Chelsea, England, March 23, 1837, and was educated at St. John's college, Cambridge, where he graduated in 1860. He published an article on "Double Stars" in the *Cornhill Magazine* for December, 1865, and from that time wholly devoted himself to the study of astronomy. He came to America on a lecturing tour in 1873, and again in 1875, where he succeeded, as he had previously done in England, in interesting large numbers of people in the science of astronomy. He died at New York, Sept. 12, 1888; and in 1890 a memorial observatory was erected in his honor near San Diego, Cal. Among his numerous works are *Half-Hours with the Telescope*, *The Sun*, *The Moon*, *Other Suns than Ours*, *Old and New Astronomy*, *Light Science of Leisure Hours*, and *Myths and Marvels of Astronomy*.

RICHARD A. PROCTOR.

Prometheus (*prō-mē'thūs*), a hero of Grecian mythology, who, on account of various services rendered to men, was chained by Zeus to a rock, where a vulture was sent to devour his liver by day, Zeus causing it to grow again by night. As Prometheus continued to endure this torture without yielding, the wrath of Jupiter was at length appeased, and the victim was released. Some legends represent the offense of Prometheus as stealing fire from heaven for the benefit of men; and in the tragedy of Æschylus he is an immortal god, a friend of the human race, who does not shrink from opposing the evil designs of Zeus against mankind, and even from sacrificing himself for their salvation. The possession of fire was very important to the early races of men, and the legend of its having been originally stolen from heaven is very widely spread over the world.

Prosenchyma (*prŏs-ĕn'kĭ-ma*) (in plants), a tissue in plants whose cells are elongated or fibrous. It is a general name covering all elongated and fiber-like cells, as distinct from "parenchyma," which is a tissue composed of cells whose three diameters are approximately the same.

Proserpina (*pro-ser'pi-na*), daughter of Zeus and Demeter. While gathering flowers on the plains of Sicily, she was abducted by Pluto and taken to his abode in the underworld, where she was found by her mother after a nine-years' search, and given up by Pluto only on condition that she should live part of the year underground. The myth is very clearly an expression of the revival of nature every year, after winter is over.

Protagoras (*prō-tag'ō-ras*) the earliest of the Greek sophists, was a native of Abdera, born about 481 B. C. The basis of his philosophy is the proposition that "man is the measure of all things." All his works are lost, and he himself perished at sea while on his way to Sicily to escape a charge of atheism brought against him at Athens. He died about 411 B. C.

Protandry (*pro-tăn'drĭ*), (in plants), a condition in which the stamens are mature and shedding pollen before the stigma of the same flower is ready to receive it. See POLLINATION.

Protec'tion is the aid given by government to particular industries by bounties, or by taxation of other industries, or more commonly by tariff or import duties on foreign products. See POLITICAL ECONOMY.

Protec'tor, a title which has sometimes been conferred on the regent or governor of the kingdom during the minority of the sovereign. Oliver Cromwell, in 1653, took the title of lord-protector of the commonwealth of England, Scotland, and Ireland, and ruled over those countries under that title until his death, in 1658.

Prot'estantism, a term derived from the *protest* of Luther and his adherents against the decree passed by the Catholic states at the second diet of Speier, in 1529. The principles involved in this protest were, that the Catholic church has no authority over the Reformed church, that the authority of the Bible is supreme and above that of bishops

and councils, and that it is to be interpreted, not according to tradition, but by its own language. The right of private judgment in reference to the interpretation of the Scriptures is the principle of Protestantism that especially distinguishes it from Roman Catholicism. Protestant churches are divided into numerous branches, with wide differences of doctrine and forms of worship, but they all agree in the assertion of independence of the Roman See.

Proteus (*prō'tē-us* or *prō'tūs*), in the oldest Greek mythology, appears as an "old man of the sea," who tends the seal flocks of Neptune, his father, and is endued with the gift of prophecy. His favorite residence, according to Homer, is the island of Pharos, near the mouth of the Nile. Here he rises at midday from the floods, and sleeps in the shadow of the rocky shores, surrounded by the monsters of the deep. But when caught by persons who sought to have him foretell future events, he would try to escape by assuming all manner of ugly shapes and disguises, and would refuse to exercise his gift until he found that further resistance would be useless.

Prothallium (*prō-thăl'lī-ŭm*), among plants, is a name applied in a general way to the gametophytes of Pteridophytes and Spermatophytes. It specially belongs, however, to the ferns, in which the prothallium, often written "prothallus," is a quite distinct but very small green and notched thallus. Upon the under side of this small body the antheridia and archegonia occur. From the fertilized egg within the archegonium the ordinary leafy fern plant arises. When in other plant groups the prothallium ceases to be independent, as in seed plants, it often retains the name. For example, many would speak of the female gametophyte (endosperm) found in seeds as a female prothallium. See GAMETOPHYTE.

Protococcus (*prō'tō-kŏk'kŭs*), a genus of plants which are among the simplest of the green algæ. The mature plants are single spherical green cells, which occur in masses. See CHLOROPHYCEÆ.

Protogyny (*prō-toj'ĭ-nĭ*) (in plants), a condition in which the stigma is ready to receive before the pollen of the same flower is ready for shedding. See POLLINATION.

Protonema (*prō'tō-nē'ma*) (in plants). When the asexual spores of mosses germinate they produce at first green branching filaments, which are prostrate and resemble ordinary green algæ. Upon this filamentous body the ordinary leafy branches arise. This alga-like body is known as the protonema. See MUSCI.

Protoplasm (*prō'tō-plaz'm*), the living substance in animals and plants. Huxley called it the "physical basis of life." It is the only substance endowed with life. It is very similar in animals and plants, and within it all living activities take place. It is a jelly-like, colorless substance, appearing finely granular under the microscope. It is composed of two parts, one more solid, which stains deeply with dyes (*chromatin*), and a fluid part (*achromatin*), which stains very faintly or not at all. The discovery of protoplasm, and the gradual appreciation of the part it plays in the living world, is one of the greatest scientific advancements of the nineteenth century. In 1835, Dujardin, a French naturalist, was studying the simplest animals (*Protozoa*) under the microscope. He observed that their bodies were composed of a sort of transparent jelly, that moved and contracted and showed evidences of being alive. This soft jelly-like substance he called *Sarcode*, and described it as living matter endowed with life. Some years after, in 1846, Hugo von Mohl, a botanist, called attention to the viscid contents of plant cells, for which he proposed the name *protoplasm*. This name had previously been used, in 1840, by Purkinje, for animal substance, but Von Mohl first brought it into general use. Presently, naturalists began to suspect that the *sarcode* of the zoologists, and the *protoplasm* of the botanists, were essentially identical in nature. This was definitely maintained by Cohn in 1850. Finally, in 1860, Max Schultze placed the matter on a secure basis, and applied the term protoplasm to all living substance, either animal or vegetable. This led to what is known as the protoplasm theory, which absorbed the cell theory of Schleiden and Schwann. By Max Schultze the cell was defined as a mass of protoplasm surrounding a nucleus. Although protoplasm is so similar in appearance and reactions in all living beings, nevertheless, there must be unperceived differences — possibly not of kind but of degree of modification. See CELL DOCTRINE.

Protozoa (*prō'tō-zō'a*), the simplest animals. Collectively, they form the sub-kingdom protozoa. They are microscopic and unicellular, and are abundant in stagnant water. They are of great interest to zoologists and physiologists because, in them, the processes of life are reduced to their simplest expression. By studying them, many facts are obtained that help in understanding the more complex animals. They have recently been studied in reference to their reactions to stimuli, and many important results obtained. The daily life of a protozoon was made the subject of study in one of our laboratories of psychology. The group includes simple forms like the amœba and its relatives, having root-like feet, and constituting the class *Rhizopoda*. Many of the rhizopods have no covering, but others either secrete a shell, or gather hard particles and build one. Chalk is largely made up of minute limy shells of protozoa. The form most common in chalk

is a cluster of globular chambers, varying in size. The walls of these shells are perforated by minute holes, through which the soft protoplasm of the animal protrudes. They constitute an order called foraminifera or hole-bearers. These animals are abundant in warm and temperate seas. They live near the surface and, as they die, their shells sink of their own weight and reach the bottom. Deep-sea explorations have brought from great depths a soft ooze, formed almost entirely of these shells of foraminifera. Somewhat similar forms make shells of great beauty, of quartz or silica, which cannot be dissolved by acid or melted by fire. They constitute the order *Radiolaria*. The higher protozoa belong mainly to the class *Infusoria* (which see). These minute animals have hair-like processes (*cilia*), which propel the body through the water like the action of many small oars. In some forms, the hair-like threads are large, and reduced in number to one or two, and are called flagella. Thus the class infusoria is separated into two divisions, the *Flagellata* and the *Ciliata*. The latter contains the highest developed of the protozoa. Among the more common forms may be noted: the slipper animalcule (*Paramœcium*), with a free swimming slipper-shaped body; the bell animalcule (*Vorticella*), with a bell-shaped body anchored by a stalk, and the trumpet animalcule, or stentor. The rhizopoda and the infusoria are the chief classes; two others of less importance are recognized. See Leidy's *Fresh Water Rhizopods of North America* (1879), beautifully illustrated, published by the United States government; and Kent's *A Manual of the Infusoria* (1880–82).
